SUBSCRIPTION RATE: $3.00 a year; $1.75, six months; $1.00, three months; postpaid anywhere

The Canadian Engineer

Published Weekly — Established 1893

A Weekly Paper for Civil Engineers and Contractors

Including chiefly municipal, railroad, hydraulic, structural, highway and consulting engineers; surveyors; mine managers; contractors; and water works superintendents

Index to Volume 37

July 1 to December 31, 1919

156036
17/9/20

Published every Thursday by THE MONETARY TIMES PRINTING CO. OF CANADA, LIMITED
HEAD OFFICE: CORNER CHURCH AND COURT STREETS, TORONTO, ONTARIO
JAMES J. SALMOND, President and General Manager *ALBERT E. JENNINGS, Assistant General Manager*
Telephone Main 7404, Branch Exchange connecting all Departments
Cable Address: "Engineer, Toronto"
WESTERN CANADA OFFICE: 1206 McArthur Building, Winnipeg G. W. GOODALL, Western Manager

The Canadian Engineer

INDEX TO VOLUME 37

July 1 to December 31, 1919

A

Abbott, C. E.; Flat Rate vs. Meters. 221.
Abrams, Duff A.; Effect of Rodding Concrete**. 491.
Abrams, Duff A.; Effect of Vibration, Jigging and Pressure on Fresh Concrete. 192.
Abrams, Duff A.; Experiments Show Effect of Fineness of Cement. 438.
Act—Regulations Under Canada Highways. 567.
Action Follows Electrolysis — Court†. 553.
Activities—Engineers Favor Employment†. 449.
Adams, Thomas; Housing and Town Planning*. 435.
Adams, Thomas; Municipal Engineers and Town Planning. 178.
Adams, Thomas; Planning and Development of Cities in Ontario. 509.
Adams, Thomas; Regional Planning of the Niagara District. 187.
Adams, Thomas; The Planning of Land in Relation to Municipal and Social Problems. 472.
Advance in Book Prices. 223.
Advantages to Owners—Concreting in Cold Weather Offers Strong; A. E. Wells. 411.
Advisory Board to Dominion Highway Branch Confers with Provincial Officials. 283.
Aeroplanes in Business Life†. 285.
Agents—Rensselaer Valve Co. Appoints. 299.
Aid in Procuring Contracts—Financial Statements in; Daniel J. Hauer. 440.
Air-Lift Pumping; Chas. J. Deem. 441.
Air-Lift Pumping*; John Oliphant. 121.
Alberta Industrial Congress. 256.
Algæ in Irrigation Canal—Screen Wheel for Removal of; E. Court Eaton. 242.
Alleys—Laying Water Mains in†. 134.
American Association of Engineers†. 499.
American Association of Engineers—No Room for Trade Unionism in Engineering Profession, Say Directors of. 498.
American Association of Engineers—Unique Membership Campaign Launched by. 444.
American Society for Municipal Improvements—The. 419.
American Water Works Association to be Held June 21-26, 1920, in Montreal —Fortieth Annual Convention. 381.
Amherstburg Filter Plant*. 526.
Amos, Arthur; Water Power Policies of the Quebec Government. 235.
Analysis of Concrete — Proportioning Theories*; Roderick B. Young. 487.
Anderson, J. T. Noble; Pressures in Penstocks Caused by the Gradual Closing of Turbine Gates. 425.
Andrew Carnegie—Death of. 247.
Approval of Plans—Municipal Bureau's. 276.
Aqueduct Arbitration—Montreal. 281.
Aqueduct Construction—Earth Slides in Winnipeg*; Douglas L. McLean. 469.
Arbitration—Montreal Aqueduct. 281.
Arbitration vs. Investigation†. 394.
Architects Meet in Toronto. 353.
Area Proportioning Method—Studies in Surface.; Llewellyn N. Edwards. 359.
Areas by the Method of Co-Ordinates—Computing Cross-Section*; J. A. McDonald.
Armstrong, J.; Backfilling the Red River Tunnel*. 367.
Armstrong, James Wadsworth; Some Observations and Experiences in the Operation of Coagulating Basins*. 405.
Armstrong, John H§. 554.
Armstrong Returns to Canada, William. 290.
Armstrong, William; Mineral Resources of Canada, with Special Reference to Lignites and Their Treatment**. 482.
Arthur Young Co.'s Classification—Objections to. 275.
Asphalt Association—The†. 499.
Association of Canadian Building and Construction Industries Constitution†. 394.
Association of C.B. and C.I. News Notes. 356.
Association of Canadian Building and Construction Industries Proposed Constitution. 381.
Association of Engineers—American†. 499.
Association of Engineers—Unique Membership Campaign Launched by American. 444.
Association—The Asphalt†. 499.
Austin, R. N.; Test Shows 82.1% Overall Efficiency of Motor-Driven Centrifugal Pumps*. 347.
Auto Truck Peril for Hydrants†. 116.
Award Highway Contracts Early!†. 499.
Awards Rescinded—Ontario Highway†. 321.

B

Babbitt, H. E.; Economics of Reinforced Concrete Walls for Uncovered Reservoirs*. 258.
Babcock, H. A.; Riveted Joints for Steel Penstocks and Tanks*. 195.
Backfilling the Red River Tunnel*; J. Armstrong. 367.
Bacteriology of Water—Studies in the; Denis B. Wood. 179.
Baird, Geo. H.§; 230.
Balbach, E.; Convenient Method of Calculating Trash Racks*. 137.
Baldwin's Canadian Steel Corporation. 243.
Baltimore—Proposed Schedule of Civic Salaries at. 393.
Bare vs. Weatherproof Wires†. 357.
Basins—Some Observations and Experiences in the Operation of Coagulating*; James Wadsworth Armstrong. 405.
Bass, Frederic; The Relation of the Engineering Profession to Engineering Education. 185.
Bates, P. H.; Cements Producing Quick-Hardening Concrete. 113.
Beall, John S.; Highways to Lower the High Cost of Living. 332.
Beams—Doubly Reinforced Concrete*; E. Montgomery. 471.
Bear River Bridge—The; A. T. Macdonald. 311.
Beaudin, J. A. A.; Piecework System in Meter Reading. 534.
Beck, Edw. H.; Quantity Surveys vs. "Payment"**. 376.
Belle Isle Dam—Strait of†. 485.
Belle Isle Straits to Change Newfoundland's Climate—Propose Dam Across. 316.
Belleville, Ont., Water Supply*. 439.
Bents—Formulæ for One-Story and Two-Story*; E. Maerker. 213.
Bill Classifying Civil Service—Council of the Engineering Institute Supports. 407.
Blanchard, Arthur H.; Education of Highway Engineers. 276.
Blanchard's Appointment — Prof.**; H. E. Riggs. 236.
Blasting Explosive—TNT as a; Charles E. Munroe and Spencer P. Howell. 170.
Block Units for Homes of Moderate Price — Lot and; Arthur Coleman Comey. 425.
Blocks for Toronto Breakwater—Making Concrete*; Frederick Phillips. 119.
Board Encountered Difficulties—Lignite. 216.
Bond Premiums on Government Contracts. 222.
Book Prices—Advance in. 223.
Books Reviewed:—
Cost-Keeping and Construction Accounting, by G. Ed. Ross. 508.
General Lectures on Electrical Engineering, by Dr. Charles Proteus Steinmetz, reviewed by A. H. Hull. 326.
"Bore for Power!" Says Sir Chas. Parsons. 417.
Boulevard—Toronto's Marginal*; Reginald B. Evans. 543.
Bowden, W. A.; Canada's Canal System. 243.
Breakwater—Making Concrete Blocks for Toronto*; Frederick Phillips. 119.
Bricknell, F. W.; Some Lessons and Problems. 337.
Bridge Inspection — Points Requiring Special Observation and Investigation in; Herbert C. Keith. 145.
Bridge—The Bear River; A. T. Macdonald. 311.
Bridging at the Front—Heavy Steel Highway*; A. C. Oxley. 377.
Briquettes Next August—Lignite. 407.
British Columbia—Forests of†. 193.
British Columbia—Power in†. 413.
British Columbia — Report on Water Powers of*. 461.

*Illustrated. **Letter to the Editor. †Editorial. ‡Author of Book Review. §Obituary.

British Columbia — Road Construction in. 572.
British Columbia—Roads of. 506.
British Columbia Technical Association. 448.
British Columbia — Water Powers of. 223.
British Columbia—Water Powers of†. 466.
British Engineering Standards Reports. 294.
British Industries Fair. 106.
British Optical Firms Busy†. 431.
Broken 24-in. Water Main—An Experience with a; S. L. Etnyre. 444.
Brookman, F. W.; Collection and Disposal of Refuse in the Future. 207.
Brown, Stephen Pearson§. 536.
Brownridge, Charles; Problems Confronting Municipal Engineers. 282.
Bureau — Quebec Municipalities' Engineering†. 413.
Bureau's Approval of Plans—Municipal. 276.
Business Life—Aeroplanes in†. 285.

C

Calculating Trash Racks — Convenient Method of*; E. Balbach. 137.
Campaign Launched by American Association of Engineers—Unique Membership. 444.
Campbell, Duncan McD.§. 414.
Canada—Central Electric Stations in†. 571.
Canada Highways Act — Regulations Under. 567.
Canada Must Develop Her Great Fuel Resources; Arthur V. White. 349.
Canada—Production of Coal in*; F. D. Gray. 238.
Canada To-day—The Railway Situation in. 529.
Canada's Canal System; W. A. Bowden. 243.
Canada's Dependence on Electric Power. 135.
Canada's Fuel Problem†. 173.
Canada's Fuel Problem—Some National and International Aspects; Arthur V. White. 141.
Canada's Needs of the Hour—Efficiency, Production and Conservation†. 321.
Canadian Building and Construction Industries Constitution—Association of†. 394.
Canadian Building and Construction Industries—G. B. Greene Heads Ottawa Branch. 561.
Canadian Building and Construction Industries Now Has Dominion Charter. 458.
Canadian Building and Construction Industries Proposed Constitution—Association of. 381.
Canadian Engineering Standards Association. 320.
Canadian Good Roads Association. 288.
Canadian Mining Institute Comment on Classification†. 394.
Canadian Steel Corporation—Baldwin's. 243.
Canal Diversion — Chicago Drainage†. 431.
Canal for Niagara—Proposes Drainage. 274.
Canal—Progress of Queenston—Chippawa Power*. 249.
Canal System—Canada's; W. A. Bowden. 243.
Case, E. D.; Water Waste Control by House Inspections with District Metering. 163.
Cauchon, Noulan; Ethical and Practical Sides of Town Planning. 512.
Cauchon, Noulan; Town Planning, with Special Reference to Ottawa. 455, 477.
Cement Co., Owen Sound—Federal. 412.
Cement—Experiments Show Effect of Fineness of; Duff A. Abrams. 438.
Cements Producing Quick-Hardening Concrete; P. H. Bates. 113.
Central Electric Stations in Canada†. 571.
Central Health Laboratory Required†. 152.
Centrifugal Pump—Test Shows 82.1% Over-all Efficiency of Motor-Driven*; R. N. Austin. 347.
Centrifugal Pumps — Horsepower Requirements of*. 237.
Charter—Canadian Building and Construction Industries Now Has Dominion. 458.
Chicago Drainage Canal Diversion†. 431.
China—Engineering Opportunities in**; P. E. Doncaster. 481.
Chlorination and Its Effect on Typhoid Fever—Advance in; John Kienle. 120.
Christie, Fred.; Trade Unionism and Engineers**. 551.
Cities for To-morrow—Zoning; W. J. Donald. 510.
Cities in Ontario—Planning and Development of; Thomas Adams. 509.
Citizen?—Are You an Unresponsive†. 265.
Civic Development—Reconstruction and; C. H. Mitchell. 423.
Civic Salaries at Baltimore—Proposed Schedule of. 393.
Civil Service—Council of the Engineering Institute Supports Bill Classifying. 407.
Civilization—Electricity and. 283.
Clamer, Gwilliam H.; Standardization. 225.
Classification and Salaries of Engineers. 397.
Classification—Canadian Mining Institute Comment on†. 394.
Classification — Objection to Arthur Young Co.'s. 275.
Classification of E.I.C. Members†. 303.
Classifying Civil Service—Council of the Engineering Institute Supports Bill. 407.
Clearing House for Information—Why Quebec Municipalities Should Have; Charles A. Mullen. 569.
"Closing" the Profession in England†. 535.
Closure—Pressure Rise Caused by Gradual Gate*; Norman R. Gibson. 269.
Coagulating Basins—Some Observations and Experiences in the Operation of*; James Wadsworth Armstrong. 405.
Coal in Canada—Production of*; F. D. Gray. 238.
Cobourg, Ont., Reconstruction of Water Works at*; A. E. Davison. 287.
Cold Weather—Concreting in*. 516.
Cold Weather Offers Strong Advantages to Owners—Concreting in; A. E. Wells. 411.
Cole, A. B.; World's Most Powerful Prime Mover*. 125.
Concreting in Cold Weather Offers Strong Advantages to Owners; A. E. Wells. 411.
Collection and Disposal of Refuse in the Future; F. W. Brookman. 207.
Comey, Arthur Coleman; Lot and Block Units for Homes of Moderate Price. 425.
Commission—Nova Scotia Power†. 431.
Commission—Nova Scotia Power. 458.
Committee for Montreal Convention. 458.
Committee—Report of Joint Committee of Technical Organizations Status†. 517.
Committee to Joint Committee of Technical Organizations—Report Presented by Status. 501.
Compensation Committee—Progress by Engineering Council's. 109.
Compensation — Ontario Hydro Asks. 264.
Computing Cross-Section Areas by the Method of Co-Ordinates*; J. A. McDonald. 561.
Concrete Beams—Doubly Reinforced*; E. Montgomery. 471.
Concrete Blocks for Toronto Breakwater —Making*; Frederick Phillips. 119.
Concrete — Cements Producing Quick-Hardening; P. H. Bates. 113.
Concrete Construction—Significance of Cracks in Reinforced; Stanley H. Harris. 333.
Concrete—Economics of Placing†. 535.
Concrete—Effect of Rodding**; Duff A. Abrams. 491.
Concrete—Effect of Rodding*; F. E. Giesecke. 217.
Concrete—Effect of Vibration, Jigging and Pressure on Fresh; Duff A. Abrams. 192.
Concrete Hardening—Acceleration of. 106.
Concrete Houses—Conference on. 568.
Concrete Materials—Proportioning of†. 375.
Concrete—Preparation of Specifications for; I. F. Morrison. 160.
Concrete-Proportioning — Investigation of†. 517.
Concrete — Proportioning of Pit-Run Gravel for*; Prof. R. W. Crum. 165.
Concrete-Proportioning Theories — Analysis of*; Roderick B. Young. 487.
Concrete Railway Track Support*. 277.
Concrete Road Construction Gangs—the Organization of Efficient; Halbert P. Gillette. 244.
Concrete Road Construction — Recommended Practice of Mississippi Valley State Highway Departments for. 260.
Concrete Road Slabs from Wheels of Heavy Trucks—Stresses in. 264.
Concrete Sands—Fine-Grained; F. E. Giesecke. 279.
Concrete Walls for Uncovered Reservoirs —Economics of Reinforced*; H. E. Babbitt. 258.
Concrete Wharf—Suggested Standard*; C. R. Coutlee. 140.
Concreting in Cold Weather*. 516.
Conference at Hamilton—Town Planning. 486, 514.
Conference at Detroit — Inter-Professional†. 466.
Conference at Ottawa—Joint Town-Planning. 403.
Conference—Inland Waterways. 494.
Conference on Concrete Houses. 568.
Conference—The National Industrial†. 357.
Congress—Alberta Industrial. 256.
Congress—National Industrial. 257.
Conservation Canada's Needs of the Hour — Efficiency, Production and†. 321.
Constituents of Garbage—Recovery of Valuable**; J. G. Pickard. 508.
Constituents of Garbage—Recovery of Valuable; Samuel A. Greeley. 495.
Constitution—Association of Canadian Building and Construction Industries†. 394.
Constitution—Association of Canadian Building and Construction Industries Proposed. 381.

*Illustrated. **Letter to the Editor. †Editorial. ‡Author of Book Review. §Obituary.

Construction Gangs—The Organization of Efficient Concrete Road; Halbert P. Gillette. 244.
Construction of Highways — Problems Affecting Design and; W. G. Thompson. 484.
Construction—Significance of Cracks in Reinforced Concrete; Stanley H. Harris. 333.
Consulting Engineering Ethics†. 246.
Consulting Firm, Gore, Nasmith & Storrie, to Specialize in Public Health —New. 322.
Consumption—Metering and Water; H. P. T. Matte. 181.
Contract—An Improved Cost-Plus†. 152.
Contract — Cost-Plus-Fixed-Fee; A. E. Wells. 301.
Contract—Cost-Plus-Fixed-Fee**; J. A. L. Waddell. 522.
Contract Forms†. 210.
Contract-Letting Made Practicable — Ideal*; Dr. J. A. L. Waddell. 527.
Contract Prices Should Lead Neither to Postponement Nor to Day Labor—High. 283.
Contractor — The Logical; William S. Wollner. 480.
Contractors for Estimating—The Case Against Payment to; William Graves Smith. 331.
Contractors for Estimating—The Kelley System of Payment to. 315.
Contractor's Salary as "Overhead"—The; J. F. Lidral. 479.
Contracts—Bond Premiums on Government. 222.
Contracts Early! — Award Highway†. 499.
Contracts—Financial Statements on Aid in Procuring; Daniel J. Hauer. 440.
Contracts — Protection of Owners on Cost-Plus*; F. A. Wells. 323.
Contracts vs. Percentage Contracts—Unit Price; W. L. Darling. 131.
Convention—Committee for Montreal. 458.
Convention—New England Water Works. 374.
Cooper, Theodore§. 286.
Co-Ordinates—Computing Cross-Section Areas by the Method of*; J. A. McDonald.
Corner—Establish an Interesting†. 303.
Corrosion—Protecting Iron and Steel Standpipes from. 368.
Corrugated Paper Used to Separate Wood Block in Paving St. Thomas Track Allowance*; John Stanley Crandell. 525.
Cost of a Mile of Road*; George A. Duren. 161.
Cost of Living—Highways to Lower the High; John S. Beall. 332.
Cost-Plus Contract—An Improved†. 152.
Cost-Plus Contracts—Protection of Owners on*; F. A. Wells. 323.
Cost-Plus-Fixed-Fee Contract; A. E. Wells. 301.
Cost-Plus-Fixed-Fee Contract**; J. A. L. Waddell. 522.
Cottrell, G. Gordon; Some Aspects of the Salvage and Wrecking Business. 346.
Council's Compensation Committee—Progress by Engineering. 109.
Courses — U.S. Engineering Council's Committee on Curricula Opposes Present Adoption of Six-Year Engineering. 443.
Court Action Follows Electrolysis†. 553.
Coutlee, C. R.; Metric System Revised**; 193.
Coutlee, C. R.; Present System is Convenient**. 173.
Coutlee, C. R.; Suggested Standard Concrete Wharf*. 140.
Cracks in Reinforced Concrete Construction—Significance of; Stanley H. Harris. 333.
Crandell, John Stanley; Corrugated Paper Used to Separate Wood Block in Paving St. Thomas Track Allowance*. 525.
Crandell, J. S.; Patrol Maintenance on Hard Surface Roads*. 542.
Creager, William P.; Pressures in Penstocks Caused by the Gradual Closing of Turbine Gates. 434.
Cross-Section Areas by the Method of Co-Ordinates—Computing*; J. A. McDonald. 561.
Crum, Prof. R. W.; Proportioning of Pit-Run Gravel for Concrete*. 165.
Crushers—Large, Portable Road*; R. R. Shafter. 274.

D

Dam Across Belle Isle Straits to Change Newfoundland's Climate — Propose. 316.
Dam—Strait of Belle Isle†. 485.
Dams—Effect of Water Uplift on Overturning of*; Erwin Maerker. 433.
Dams—Effect of Water Uplift on Overturning of***; E. Maerker. 491.
Dams Proposed for St. Lawrence River —Four. 545.
Dams—Water Pressure Under†. 449.
Darling, W. L.; Unit Price Contracts vs. Percentage Contracts. 131.
Davison, A. E.; Reconstruction of Water Works at Cobourg, Ont.*. 287.
Day Labor—High Contract Prices Should Lead Neither to Postponement Nor to. 283.
Dayton — 10,000,000-Gal. Reservoir at. 369.
Death Rate—Garden City's Low Infant. 513.
Death Rates—Sanitation and Municipal; George A. Soper. 475.
Deem, Chas. J.; Air-Lift Pumping. 441.
Denis, L. G.; Detection of Water Waste. 187.
Denis, L. G.; Super-Power Plants. 243.
Depreciation to Investment—The Relation of; W. C. Hawley. 127.
Design and Construction of Highways—Problems Affecting; W. G. Thompson. 484.
Detroit — Inter-Professional Conference at†. 466.
De Vall, C. L.; Frost Heaves Street Railway Paving Slabs in Edmonton*. 493.
Development of Cities in Ontario—Planning and; Thomas Adams. 509.
Development of Hamilton Harbor—Proposed*; John M. Wilson. 537.
Development of the South Shore of the St. Lawrence River Opposite the City of Montreal—The Future*. 532.
Development on the Seguin River — Hydro-Electric*. 231.
Development—Reconstruction and Civic; C. H. Mitchell. 423.
Development—Town Planning in Relation to Industrial; C. W. Kirkpatrick. 524.
Diehl, George C.; Cost and Service of New York State Highways. 190.
Difficulties—Lignite Board Encountered. 216.
"Direct Oxidation" Experimental Sewage Treatment Plant at Easton, Pa.—Operating Results of*. 389.
Disease—More Flushing, Less†. 571.
Disposal of Refuse in the Future—Collection and; F. W. Brookman. 207.
Disposal Problem—Present Status of the Sewage; Dr. George G. Nasmith. 519.
Disposal Problem—Toronto's Sewage†. 339.
Diversion — Chicago Drainage Canal†. 431.
Dobson, John§. 572.
Dominion Charter—Canadian Building and Construction Industries Has No. 458.
Dominion Highways Branch Confers with Provincial Officials — Advisory Board to. 283.
Donald, W. J.; Zoning Cities for Tomorrow. 510.
Doncaster, P. E.; Engineering Opportunities in China**. 481.
Downey, Joseph A.§. 486.
Drafting Practice—Rules for. 388.
Drafting Practice—Rules for**; Gerald Hamilton. 432.
Draftsmen's Association Organized. 244.
Drainage and Foundations—Road; Geo. Hogarth. 300.
Drainage Canal Diversion — Chicago†. 431.
Drainage Canal for Niagara—Proposes. 274.
Draney, J. R.; Correction**. 170.
Drifting Sand Filters at Toronto—Operation of*; Norman J. Howard. 341.
Drifting Sand Filtration in Toronto**; George A. Johnson. 507.
Duff, Louis Blake; The Town Plan and the Factory. 544.
Duren, George A.; The Cost of a Mile of Road*. 161.

E

Earth Slides in Winnipeg Aqueduct Construction*; Douglas L. McLean. 469.
Earthwork—How to Reduce Risks in; Halbert P. Gillette. 224.
Eastern Canada—Town Planning in. 284.
Eastern Part of York Township, Ont.—$2,357,000 Sewerage Scheme Recommended for*. 540.
Easton, Pa.; Operating Results of "Direct Oxidation" Experimental Sewage Treatment Plant at*. 389.
Eaton, E. Court; Screen Wheel for Removal of Algæ in Irrigation Canal. 242.
Economic Values in Sewage and Sewage Sludge; Raymond Wells. 563.
Economical Size of Pipe for Given Loss of Head*; Prof. E. W. Rettger. 148.
Economics of Placing Concrete†. 535.
Edmonton—Frost Heaves Street Railway Paving Slabs in*; C. L. De Vall. 493.
Edmonton Public Utilities Improving. 126.
Education—The Relation of the Engineering Profession to Engineering; Frederic Bass. 185.
Education of Highway Engineers; Arthur H. Blanchard. 276.
Edwards, Llewellyn N.; Studies in Surface Area Proportioning Method*. 359.
Effect of Fineness of Cement—Experiments Show; Duff A. Abrams. 438.
Effect of Rodding Concrete**; Duff A. Abrams. 491.
Effect of Water Uplift on Overturning of Dams***; E. Maerker. 491.
Efficiency, Production and Conservation Canada's Needs of the Hour†. 321.
Elections—Engineering Institute. 211, 257, 357, 450, 531.
Electric Power—Canada's Dependence on. 135.

*Illustrated. **Letter to the Editor. †Editorial. ‡Author of Book Review. §Obituary.

Electric Power—Widening Radius for. 476.
Electric Stations in Canada—Central†. 571.
Electricity and Civilization. 283.
Electrification—The Prospects of Railroad; F. H. Shepard. 387.
Electrolysis — Court Action Follows†. 553.
Elevator Investigation—Port Colborne†. 229.
Employment Activities—Engineers Favor†. 449.
Engineering Bureau — Quebec Municipalities†. 413.
Engineering Council's Compensation Committee—Progress by. 109.
Engineering Courses—U.S. Engineering Council's Committee on Curricula Opposes Present Adoption of Six-Year. 443.
Engineering Ethics—Consulting†. 246.
Engineering in Modern Warfare—Light Railway*; Lieut. C. H. R. Fuller. 101.
Engineering Institute Elections. 211, 257, 357, 450, 531.
Engineering Institute of Canada Members—Classification of†. 303.
Engineering Institute of Canada—Ontario Provincial Division. 500.
Engineering Institute of Canada President—R. A. Ross to be. 414.
Engineering Institute Supports Bill Classifying Civil Service—Council of the. 407.
Engineering Opportunities in China**; P. E. Doncaster. 481.
Engineering Profession, Say Directors of American Association of Engineers —No Room for Trade Unionism. 498.
Engineering Profession to Engineering Education—The Relation of the; Frederic Bass. 185.
Engineering Standards Association — Canadian. 320.
Engineering Standards Reports—British. 294.
Engineering—Usefulness of Vegetation in Maritime*; E. T. P. Shewen. 327.
Engineering Work at the Front†. 553.
Engineers—American Association of†. 499.
Engineers and Town Planning—Municipal; Thomas Adams. 178.
Engineers—Classification and Salaries of. 397.
Engineers—Education of Highway; Arthur H. Blanchard. 276.
Engineers Favor Employment Activities†. 449.
Engineers—Problems Confronting Municipal; Charles Brownridge. 282.
Engineers—Salary Schedule for Highways†. 571.
Engineers—Trade Unionism and**; Fred. Christie. 551.
Engineers—Trade Unionism and**; N. C. Mills. 562.
Engineers—Unique Membership Campaign Launched by American Association of. 444.
England—"Closing" the Profession in†. 535.
Essex Border Water Works. 567.
Establish an "Interesting Corner"†. 303.
Estimates—Supplementary. 124.
Estimates—To Consider Pay for. 434.
Estimating—H. W. Nelson's Plan of Payment for. 445.
Estimating—The Case Against Payment to Contractors for; William Graves Smith. 331.
Estimating—The Kelley System of Payment to Contractors for. 315.
Ethical and Practical Sides of Town Planning; Noulan Cauchon. 512.
Ethics—Consulting Engineering†. 246.
Etnyre, S. L.; An Experience with a Broken 24-in. Water Main. 444.
Evans, Reginald B.; Toronto's Marginal Boulevard*. 543.
Expenses — Effect of the War Upon Water Works' Revenues and; Leonard Metcalf. 111.
Experimental Sewage Treatment Plant at Easton, Pa.—Operating Results of "Direct Oxidation"*. 389.
Explosive—TNT as a Blasting; Charles E. Munroe and Spencer P. Howell. 170.
Exports—Large Imports and†. 413.

F

Factory—The Town Plan and the; Louis Blake Duff. 544.
Fair Play for the G.T.R.†. 321.
Federal Cement Co., Owen Sound. 412.
Ferry Service—Saskatchewan's Public*; G. A. Palmer. 523.
Field — Mathematicians Enter Industrial†. 229.
Filter Manufacturing Co.—Agents for Roberts. 108.
Filter Plant—Amherstburg*. 526.
Filter Plant—Proposed Peterboro'. 552.
Filters at Toronto—Operation of Drifting Sand*; Norman J. Howard. 341.
Filters at Toronto—Operation of Slow Sand; Norman J. Howard. 317.
Filtration in Toronto—Drifting Sand**; George A. Johnson. 507.
Filtration Works, Montreal—Point St. Charles*. 155.
Financial Statements on Aid in Procuring Contracts. Daniel J. Hauer. 440.
Financing of Highway Improvements; J. E. Pennybacker. 132.
Fineness of Cement—Experiments Show Effect of; Duff A. Abrams. 438.
Fire Lines—Water Departments and Private; Dow R. Gwinn. 335.
Fires—Generator. 239.

The Canadian Engineer

A Weekly Paper for Civil Engineers and Contractors

Light Railway Engineering in Modern Warfare

Principles of Construction, Maintenance and Operation — Movement of Supplies, Ammunition and Troops — Different Types of Light Railways Built by French and British Armies — Their Use in Gas Attacks — Inner Rail of Turnouts Slightly Raised

By LIEUT. C. H. R. FULLER
Formerly Assistant Engineer, Toronto-Hamilton Highway Commission

IN the construction of standard gauge railways, highways and canals in Canada and the United States, light railways, in the last few years previous to the war, assumed a prominent part. The wise and energetic contractor or engineer found it cheaper to grade or haul material for his work, directly to the spot required, by light railway than by the old method of teams.

The nearest standard gauge railway siding is sought for, and the light railway laid from this to the work in question. Material is then transhipped and hauled to the work by flat cars or other types adjusted to the light rail.

In grading, the light railway may be laid parallel to the highway proposed or railway, as the case may be, and earth moved from cuts to fills by trains of dump-cars, thus reducing the cost to a great extent. As the work advances, the light railway rails are pulled up and moved ahead, the weight of the rails lending itself to this.

Value Not Realized at First

During the first year of the war the value of light railways was not realized; in fact, the British army, outside the building of a few trench tramways, had practically none at all; however, towards the end of the first year a few light railways were constructed on the Somme by Canadians and Royal Engineers. These lines were mainly lines connecting broad-gauge railways to R.E. dumps for carrying materials.

STANDARD TYPE OF BRIDGE ERECTED BY THE CANADIAN RAILWAY TROOPS

The value of light railways used in the little work they performed during the first year was soon realized. An increase in the number of technical units or construction and operation of this type of railway immediately took place, most of the construction being handled by Canadian railway engineers and operation by Royal Engineers and Australians. Light railways then came into operation on all fronts, and an organization to handle this branch became imperative. A director of light railways for the British army was created; under him, for each army, were assistant directors. Each A.D.L.R. had his own organization for each armmy, which subsequently became as follows:—

A Light Railway Chief Engineer, in charge of construction, etc.; a Superintendent of Operation; an Army Locomotive Superintendent; and an officer in charge of telephones and signals.

BRICK ARCH NEAR COURTRAI BLOWN OUT BY HUNS, TRACKS CURIOUSLY REMAINING INTACT

When a construction unit comes into an army area, they automatically come under the A.D.L.R. for that army, and, consequently, the Army Chief Engineer. An operating company is controlled by the Superintendent of that army.

This organization was brought into a state of greater efficiency by opening up minor appointments in different parts of the work where needed.

Canadian Railway Units were in a corps composed of themselves alone for administration, discipline, etc., under a brigadier-general, but were distributed all along the front under different army A.D's.L.P. for their technical work.

Principles of Supply in an Army

The service of supplies in an army is assured by means of: (a) Supply depots on lines of communication; (b) railway trains; (c) mechanical transport supply columns; (d) trains; (e) supplies carried by transport units and the individual.

Supply depots may be base depots, main supply depots, or field depots. A base supply depot is located at the base of operations to receive supplies from overseas. Main supply depots are placed along the lines of railways or at an advanced base. Field depots are small, temporary depots in the immediate neighborhood of troops.

Troops are supplied with supplies by rail and fast-moving mechanical transport, delivering daily to trains, and thence to troops from railheads. At railheads the supplies are received by the supply columns and conveyed to rendezvous and refilling points. A rendezvous is a spot where representatives of the H.Q. concerned, order the supply columns to refilling points situated in the locality concerned. These are usually fixed at the actual refilling point.

Ammunition differs somewhat from the system of supplies on account of the fact that the replenishment of ammunition is more or less spasmodic, and neither the precise quantities nor the times they will be wanted can be exactly foreseen.

ANALYSIS Traffic Dead Weight Tonnage Standard Weights	SECTION Ouderzeele Tons	Watou Tons	Vox Vrie Tons	Weston Hoek Tons	Total Tons
Personnel	90	1,851	2,322	3,027	7,290

*Includes 32,267 tons in French System.

The reserves of ammunition are divided as follows: (1) Regimental reserves; (2) artillery brigade ammunition column reserves; (3) divisional ammunition column reserves.

Parks are placed within easy reach of ammunition columns, who carry the ammunition forward. Refilling points may be placed at various distances from the parks to suit the situation.

"Personnel" includes the movement of troops, which is usually carried out by means of standard gauge trains and marches. Motor buses and lorries are also used for quick movements.

Wounded are brought to field ambulance units by ambulances or stretchers from advanced dressing stations and taken to clearing hospitals in ambulances.

Light Railways Supersede Older Methods

Light railways have superseded the supply column to a great extent. All kinds of supplies, such as trench material, steel, sandbags and cement, are carried from the supply depots to the most advanced dumps directly by light railway. Approximately 400 tons of R.E. material may be hauled in twenty-four hours on an army front under ordinary conditions of trench warfare, besides other supplies.

Under ordinary conditions of warfare, contours of country, etc., most ammunition is hauled from refilling points in the back areas to forward area dumps, or else direct to the batteries concerned. For heavy batteries ammunition is often transhipped directly from a railhead to light railways, and hence direct to batteries. These conditions illustrate the amount of labor and handling of ammunition which is done away with by making use of light railways. Many batteries are so situated that it would be impossible to get ammunition into them efficiently by any other way except by a light railway. Main lines are constructed through a battery area, with spurs running into each battery to be supplied. These main lines are connected in the rear by lateral lines and various other back area lines, enabling dumps to be placed out of reach of forward area shelling, although they may be subject to some long range shelling and bombing.

Another advantage of using light railways is the fact that they may be built through the front between roads. Ammunition carried along roads is subject to far heavier shelling owing to the fact that they are usually well marked by enemy batteries. A light railway is hard to range on, and when it is broken, is it very quickly repaired, causing practically no delay.

Within 500 Yards of the Trenches

Two thousand tons per twenty-four hours of delivered ammunition is an average carried by light railways under ordinary conditions. If abnormal battle conditions exist, as much as 5,000 tons may be carried forward.

Light railways are usually built up to within 500 yards of the trenches in the forward area. This enables them to be used also for the transport of infantry, working parties, etc. An infantry battalion going into rest, or a battalion going up to the front, may be brought directly back to approximately the location of their rest billets or taken up to within a short distance from their location in the trenches. This has a great advantage over the long marches "up the line" over roads constantly under shell-fire. Wounded cases are brought back directly to clearing hospitals from advanced dressing stations, which advantage is obvious.

The amount of personnel handled in twenty-four hours by light railways, of course, depends on the character of the front. If an offensive is in operation on one part of the front, more personnel will be carried than on a comparatively quiet front, although it is impossible to carry all the troops in the area and other supplies as well. On the Ypres front in May, 1918, approximately one complete division was carried forward to relieve another division which was carried out of the line back to rest stations, besides carrying on the supply of ammunition and material at the same time. The accompanying table shows the minimum mileage and tonnage figures per week in the Ypres system.

A new use of light railways was brought into use by the cloud gas attack during the end of the month of May, 1918. The method of operation was as follows:—

The object of this gas attack near Ague and Tmulet was to discharge gas at a very high concentration to produce a cloud of gas that would penetrate in lethal strength to a considerable depth behind the enemy's lines. The cloud was estimated to be highly lethal to a depth of 9,000 to 10,000 yards from the point of discharge.

The gas was discharged from trains of special trucks, containing cylinders fitted with an electrical device for opening all cylinders simultaneously. These trucks were conveyed from railway bases to power heads by tractors on the light railway. Forward of power heads, infantry pushing parties, consisting of fifteen parties of twenty men each, pushed the trucks ahead. Each light railway forward line was allotted seventy-five trucks, each containing twenty-one cylinders. The number of cylinders amounted to about 4,725 in all.

The seventy-five trucks were sent up along each line in seven trains of ten trucks and one train of five trucks. The pushing parties, after pushing to the discharge points, were withdrawn to a trench system in the vicinity, where they awaited the completion of the attack. After completion, the pushing parties organized as before, hauled the empty trucks back to power heads by means of 40-foot ropes,

which were used to keep the men away from residual gas. On reaching the power heads the trucks were made up into trains as before and conveyed by tractors back to the railway bases.

Royal Engineers load cylinders into the trucks and provide a sapper to accompany each truck. Maintenance of track was carried on during the attack by Canadian Railway Engineers, who ensured that the track stood the loads required. An adequate supply of material and tools were kept ready to fix breaks due to shell-fire. The importance of this is shown by the fact that due to breakage of tracks by enemy shell-fire the attack was delayed one hour and three quarters, although the track was immediately repaired.

A pilot engine was used to travel in front of each group to avoid every chance of delay by collisions and breaks in track, etc.

In order to carry out this attack, the Light Railways on the day previous had to be closed to ammunition and food supply from 12 o'clock noon onwards. It was arranged that two days' supply would be taken up on a previous day, thus allowing for one day's supply to be used following the night of the gas attack.

Construction of Light Railways

The following types of light railways existed in France during 1918:—

(a) Metre gauge railways.—Weight of steel 451 lbs. per yard.

(b) Light railways, 2 ft. gauge.—Weight of steel 20 lbs. per yard.

(c) French light railways, 60 c.m. gauge.—Weight of steel 9.5 kilos per yard.

(d) Artillery decauville, 60 c.m. gauge.—Weight of steel 9 kilos per yard.

Metre gauge railways were in use in France and Belgium long before the war. The rolling stock is limited and is seldom used except by French and the civic governments. Latterly they were used more extensively.

Light railways are the railways most used in the British army, which we are considering in this article. The gauge is 2 ft. and weight of steel 20 lbs. per yard. In back areas and rear forward areas wooden ties are used. In front areas sectional steel, assembled on steel ties with clip bolts, are used to ensure greater speed in maintenance.

The French light railway has slightly less weight than the English light railway, due to the fact that the French system of standard weights includes the ties, fastenings and both rails.

Artillery decauville is assembled steel on steel ties. It is primarily used for pushing small flat cars about in a battery position and also used for trench tramways in the extreme forward line. Locomotives are not used on it. It is valuable in serving as the connection between the light railway spur and the actual guns.

On Fronts After Advance

On the ordinary stationary front caused by the continual trench warfare, with little variance in the trench line of either side, a system of light railways is quickly built and reaches a point where maintenance and a few extra spurs here and there is the only work carried on; however, an advance by our forces quickly throws the construction machinery into action. Gun spurs, spurs into ammunition dumps, R. E. dumps, etc., then become useless due to the forward movement of batteries, dumps, dressing stations, etc. The main lines must quickly be extended to the forward batteries and spurs built into new positions. New switch lines must be constructed so that no delay occurs in the forward movement. New locomotive and storage yards also must be built forward of their former locations.

After an Enemy Advance

If the advance by the enemy is over considerable territory, necessitating a retirement (for strategical reasons) of the whole army affected, the network of light railways becomes nonexistent and must be relayed farther back to conform to the new front. This was especially the case after the German advance on the Ypres front extending to south of Armentieres in 1918. Every one knows the old military principle that a line of communication must run at right angles to the front line. After the enemy's advance a decided salient was created, causing the line of communication to swing around to the northwest to conform, thus causing the necessity of a large increase in new light railways to be built rapidly to serve new ammunition depots, new refilling points, new R. E. dumps, new workshops, new clearing hospitals, etc.

This causes a feverish activity on the part of railway engineers, who work day and night building up a new system. The light railway line which exists farthest from the front line should be extended to enable all rolling stock, etc., to be evacuated quickly in case of a further advance by the enemy. Lines are constructed running parallel to the new front line caused by the salient. Every consideration is given to running lines to meet standard gauge railways for transhipment purposes. Spurs are constructed to serve ammunition depots, and in the case of the Ypres area it was

BRIDGE BETWEEN LILLE AND BRUSSELS DESTROYED DURING HUN RETREAT—REBUILT BY CANADIAN RAILWAY TROOPS

decided to built light railways in the French army area due to the close co-operation of the two armies at this stage.

When the above work is completed it is thought advisable to construct cross lines to serve reserve battery positions which are constructed in case of another advance by the enemy. Also in the new forward area all locomotive yards and storage yards are dismantled, leaving only the running tracks over the main lines. Any lines which are double tracked and are in the new forward area are also torn up, leaving only a single track. It was at this stage that the French army realized the full importance which was attached to the light railways and many appreciative remarks were made regarding this work. A letter from the general commanding the French army of the north appears on the next page.

On New Fronts

On new fronts devoid of light railways, an entirely new system, both in forward and back areas, must be built up. This will happen in an area taken from a force of different nationality than our own. A system of forward lines to feed batteries and dumps is first considered but not constructed. There may be three to six forward main lines decided on. Then a main back area line is located and built to serve the forward main lines which are then constructed in turn. As the track advances, forward locomotive and storage yards are constructed, spurs built into forward standard gauge lines for transhipment and the usual spurs to serve batteries.

Before an Advance

This is a case of advancing light railways as far as possible towards the trenches and constructing a few new

spurs into advanced dumps established preparatory to the advances.

It was shown in 1918 that light railways could be maintained and constructed ahead of the H.Q. of the infantry battalion in the line. This enables the advance of our forces to be closely followed up by a network of steel and thus assisting their progress by bringing up supporting troops quickly from back areas to the line and delivering rations and ammunition.

In order to carry this out, a railway map of the existing light railway lines in the front under consideration should be consulted. The lines which could be used as main lines and those which could be used as cut-off lines or avoiding lines should be picked out and placed under increased maintenance so that these may be in the best running condition possible at the moment of the advance. As soon as the advance, progresses, if it is successful for

---

(Translation)

General Plumer, Commanding,
2nd British Army.

The chief lines making up the new network of 60 c.m. railways, the construction of which was decided last 12th May, have been completed by the British Army in every case very satisfactorily, very quickly, and well constructed.

I have the honor to express to you my very sincere thanks for the co-operation and the valuable aid which is given us also by the 60 c.m. railway construction services of the 2nd British Army.

Remaining yours respectfully,

(Signed) H. de Mitry,

Commander of Detachment of the Army of the North, French Forces.

---

any reasonable distance, the lines decided on should be immediately constructed on ahead with the avoiding lines so that ammunition, rations, etc., will follow without delay.

Before an Enemy Advance

The knowledge that an attack on any front is pending is usually gained by information received from prisoners, aerial observation and from our own spies; preparations should then be made in case it is necessary to retire for a short distance as after an enemy advance.

The strictest attention should be directed to light railway bridges the size of which would be sufficient to warrant demolition to cause delay to the enemy advance. These should be mined by means of gun cotton and fuses and sentries posted ready to demolish on receipt of orders from the proper authority.

Surveys, Construction and Maintenance

The principles of surveying and locating standard gauge railways in any country should be made to apply in light railway work. In some armies light railways are not surveyed but constructed only on information gained by a preliminary reconnaissance. This is poor practice and at the present time experience has shown that instrumental surveys and proper preparation of plans and profiles will give better results.

The first step in connection with any proposed light railway line should be to obtain the best available maps of the country in question. Sheets on a scale of 1/20,000 are very useful. On such maps routes may be sketched and a very good idea of the maximum grades of the railway obtained. Routes which are obviously unsatisfactory are eliminated from further consideration. Those that look favorable should be examined by travelling over them. This method minimizes the actual amount of field examination. Grades, curvature, length of time, earthwork and character of soil, bridging and general drainage should be taken into consideration.

Of course, in all consideration of these matters, the serving of R.E. dumps, ammunition dumps, gun positions, A.R.P.'s, etc., should not be lost sight of. The traffic to be accommodated by the proposed light railway may be heavy in one direction and light in the other, in which case a grade of 1 per cent. may not be as serious in one direction as a grade of 0.5 per cent. will be in the opposite direction.

An approximate route having been decided on, a preliminary survey is run, composed of a transit party, level party and an officer in charge. A profile of the preliminary line should be kept up to date during the progress of the survey to give aid in judging whether to push ahead or back up and run the line over different ground. On completion of the preliminary survey the final grade line is decided on and placed on the profile, due regard being given to keeping total quantities of excavations and embankments to a minimum. Long cuttings should be avoided, especially in the forward area. Vertical curves are not used, but short breaks in grade may be decided on to ease, for instance, a level grade connecting a 1 per cent. grade.

Lines should not be located across in front of artillery positions but always in rear when possible. Broad gauge crossings should be 90 degs., 75 degs., 60 degs., or 45 degs. Metre gauge crossings should be made to conform with above angles as nearly as possible. Main lines should not parallel roads closer than 200 yards distance and should be located to serve groups of batteries and not single units.

Plans of proposed lines are plotted on a scale of 200 ft. to 1 in. They should show nature of ground, buildings, roads and other railway lines, streams, the kind of crop and measurements of trees, etc., which may be destroyed. Profiles are plotted on scales of 200 ft. to 1 in. horizontally and 10 ft. to 1 in. vertically. A route map on standard square system must always be prepared to accompany plan and profile. Yard and station plans are plotted on a scale of 40 ft. to 1 in.

Construction by Railway Engineers

Grading.—On authority being received to commence construction, various units should be attached to railway engineers for unskilled labor. Each railway battalion is equipped with a complete set of slush escapers hauled by mule teams, which are used to grade the heavier portions of the line. A level party must lay out the work by means of slope stakes before grading. Quantities must not exceed 3,000 yards a mile. The general principles of standard gauge railway practice should be made to apply to light railways. A sufficient berm must be left between borrow pits and the toe of the embankment. All culverts should be properly bedded to take care of the drainage. Culverts should always be laid at right angles to the line diverting drainage courses where necessary. Concrete 8 ins. and 12 ins., and corrugated pipe 18 ins. and 24 ins. diameter are used.

Bridges.—Where a single span only is required, wood stringers 9 ins. by 18 ins., or 8 ins. by 16 ins., should be used. Wherever the soil is unsuitable, in case of wide spans, pile foundations will be driven by a track driver. A record of driving must be kept, giving penetration measurements.

Bridges should be avoided, if possible, in the forward areas, owing to their vulnerability. Another important point to note is that shore bents are not placed on sills but pile driven invariably.

Track.—Rails of 20 lbs. per yard are used on all lines. Track is laid with staggered or broken joints with nine ties per five metre rail length. If the formation is very soft, this number may be increased by two. Joints are supported and not suspended. In the case of soft formations, 5-in. by 2-in. slabs are laid under the ends of the ties, particularly inside of curves.

Assembled track is laid with even joints and 2,929 steel sleepers per mile. When metre gauge ties are used ,the spacing is 2 ft. 6 ins. centre to centre of the ties. Gauging should be most accurate, especially on curves. Tie plates shall be used, two per tie, on all curves of a lesser radius than 100 metres. Guide rails may be placed where necessary on inner rails.

All turnouts are of 30-metre radius. Where the turnouts are riveted through steel ties, the two rivets tying the check rails to the two centre ties are cut out. The centre

block is removed and check rail jim-crowed, so that the clearance between it and running rail is 1¼ ins. The bolt, if present, is replaced and tightened and the block of wood wedged in between the check rail and the throat of the frog.

In case of unriveted turnouts, the gauge at the nose is exactly 2 ft. and a block of wood inserted between the middle of the check rail and the throat. The gauge throughout the curved part should be ⅜-in. slack, easing off to the heel of the switch in a length of about 4 ft.

In order to facilitate the passage of Baldwin and petrol electric locomotives, a slight raise of the inner rail on turnouts has been found most satisfactory. This is an important point to remember in light railway practice.

The gauge of all curves should be ⅜-in. slack, except where rails are riveted to steel ties, which, of course, cannot be altered.

Four spikes should be used on each tie, two inside, opposite one another, and two outside. On curves, eight spikes per tie should be used.

One-eighth-inch expansion should be left at the joint in each five metre rail length. Experience has shown that no elevation should be put on the outer rail of 50 metre curves. On 30 metre curves a slight super-elevation should be placed on the inner rail. This is done on account of the passage of very slow-moving trains hauled by Baldwin locomotives. One-half inch elevation on outer rail should be applied to curves of 100-metre radius.

Ballast.—Every attempt should be made to obtain ballast locally, particularly from ruined brick buildings. Ballast is also brought in by train. It may be sand or mine earth.

The minimum allowance of ballast per running yard of track is 0.2 cubic yards. The width of ballast should be 6 ins. beyond the end of the tie. The average lift is 6 ins. under the tie, made in two lifts of 3 ins. each, well tamped, two men working diagonally packing under the rail. Earth on no account should be packed on the ballast shoulder, as this stops drainage. A light earth skimming may be thrown on top of light sand ballast to prevent loss through wind storms.

Road and farm crossings should be built as required. Mine earth approaches and an inner platform of four rails inside the running rails and outer guard rails, filled with mine earth well packed, make good crossings.

Reports.—These should be turned in by company commanders to their chief engineer daily and weekly on a standardized form.

Daily reports should indicate the area in charge of the company, number of officers and other ranks employed on the work, including attached labor, also the number employed on each class of work. Work is usually classified as follows: Grading, tracklaying and ballasting, in yards lineal; unloading B.G. cars and distributing L.R. cars, number of cars; dismantling of track, number of rails, ties, etc.; salvage of mine earth, number of cars of light railway.

A separate daily report should show the number of breaks in last 24 hours, on account of shell fire, with time and main locations. Also another daily report should indicate the detail of work by power allotted to the construction unit. Weekly reports should show total grading, ballast, tracklaying, tons of ballast in dumps, amount of track salvaged during week, etc.

Maintenance

Forward Area.—Maintenance in the forward area is probably the most important part of light railway work, where the highest technical skill is required.

It is most essential that forward area lines be intact and in fine working order at all times. Patrols of all lines in charge of an officer of technical knowledge should be placed day and night. The patrol should be able to tell quickly what part of the lines require repair and to be placed under increased maintenance.

Assembled steel is usually used to repair shelled out track quickly. As many as 50 breaks may occur on a line in 24 hours. This will make it difficult for any but highly skilled railway construction men to keep the lines open for operation. Care should be taken that too much attention is not paid to any one section of line when other sections are in need of ballasting and lifting. Gauge of track should be checked continually. A sufficient supply of reserve material should be kept to repair blown-out track.

Forty miles of forward area maintenance may be handled by one company of railway engineers. Five or six petrol tractors should be allotted to each company and about twelve box cars. The line is patrolled by four or five patrols, each travelling by means of a train, made up of a tractor, one box car carrying the personnel, one box car of ballast and one box carrying steel rails, ties, tools, etc. Each patrol has a certain area to keep up. The strength of each patrol depends on the condition of the track in its area and the amount of shell fire and blown-out track.

It is found that the light railway lines lying between the trenches and the battery area require very little maintenance, while the track running through the battery areas requires the most maintenance. Consequently, parts of battery areas should be allotted to all patrols. It is found that spurs to batteries and tracks running along sides of roads are shelled out more than other parts of the lines. Hence, all such track should be carefully examined by patrols.

Back Areas.—The maintenance work in back areas is much different from forward maintenance, since track is very rarely shelled out. The principle of patrols being placed on the lines still exists but not necessarily in the same strength. Ballasting and lining is the principle work carried on. Attention should be paid to spurs which are used continually. Unloading of standard gauge ballast trains should be done by the company in charge of back area maintenance.

Construction of new spurs required is also part of the work of back area maintenance. Civilian labor may sometimes be used as maintenance patrols under supervision of back area maintenance engineers.

Operation of Light Railways

The general organization for operation is a superintendent, a chief traffic officer, central control, district controls and controls in sections.

All traffic matters of operation will be dealt with by the traffic officer. He should be on two telephone systems, with direct telephone. The central control and, under his orders, the district controls, do the actual operation of the line. N.C.O. traffic inspectors are also appointed. These men and a district control officer are forward every night to check up the deliveries.

Traffic priority is usually as follows:—Personnel, rations, heavy ammunition, field ammunition, R. E. material, construction material, wounded and stretcher cases returning home from forward area, unless otherwise stated by control.

Ammunition (heavy) is loaded at the railhead as in field ammunition. This will be labelled "day" or "night" by the railhead ordnance officer, and a copy of this on paper, giving wagon number, number of battery, and light railway group station name is shown. Ammunition marked "day" goes forward by steam power as early as possible by a transfer engine to a selected point. It then goes forward to its destination by petrol power. Ammunition marked "night" goes forward by steam power to a selected point and leaves in convoy at dusk.

Field ammunition goes direct to batteries at night. These trains remain at a selected point during day and go forward by night, using petrol power, as points of delivery are, as a rule, well forward.

The normal train for light railway work at night should, if possible, be five wagons (59 tons), otherwise there is a loss of power. It is more satisfactory to send five wagons for three nights per week, than fifteen wagons one night, or two wagons six nights and three on a seventh.

All engines and tractors should be supplied with re-railing ramps. Maps showing light railways and names of stations should be supplied to all concerned.

The types of petrol locomotives used in the forward area, with their permissible loads, are as follows: Petrol electric, 45 tons; 40 h.p. tractor, 35 tons; 20 h.p. tractor, 16 tons.

Steam power should always be used in the back area, saving the petrol power for forward work. Several points in connection with conservation of power follow:—

(1) In 1918 the value of light railways was better realized than at any previous time. This caused a shortage of power and rolling stock and made necessary the greatest economy.

(2) About 15% of total power and stock available was allotted to construction units for hauling material. Power and wagons not actually required by these units should always be released to operation department.

(3) Locomotives and tractor parts were very scarce.

(4) Shop facilities for making repairs were entirely inadequate.

In view of the above, every care of power and rolling stock was enforced.

Varous operation rules follow here which also apply in forward area:—

(a) Trains should not run by a section control post without securing right of way by a green flag being shown.

(b) Trains should not be allowed to stop in between controls without notifying the control.

(c) Trains should not get right of way to one point and branch off to another.

(d) Loading or unloading on main line should not be permitted.

(e) No wagon bearing a repair label should be put into traffic.

(f) Engine fires should not be drawn in ammunition dumps. Cases of this have caused fires.

(g) Locomotives must not take water at odd places on the main line but at regular watering stations.

(h) Brigade reliefs should have priority over all other trains, personnel or otherwise.

The general analysis in back areas shows haulage of material, rations, etc., from railheads to ammunition refilling points, forward dumps, etc. This material is carried ahead from the forward dumps by other trains as required.

Military Importance of Light Railways

A railway system is a highly sensitive machine, easily dislocated by unskilled treatment. It is at the same time an organism most vital to the maintenance of the army. Subject to considerations of tactical security, the convenience of individual bodies of troops must be subordinated to the efficient working of the line as a whole.

BRITISH INDUSTRIES FAIR

THE British Industries Fair, to be held in 1920, will be limited to firms whose works and head offices are situated within the British Empire, and which are not controlled by foreign interests. In other words, as regards Canada, only such manufacturers as come within this definition will be eligible to exhibit. The fair will be held simultaneously in three different cities—London, Birmingham and Glasgow—representing three distinct sections, grouping various industries. Attention is drawn to the fact that these industrial fairs are not exhibits, but trade fairs, to which admittance is restricted to *bona-fide* buyers, seriously interested in the participating trades, and that admission is by invitation only, the general public being excluded. A preliminary event open this year for a period of eleven days drew an attendance of 17,600, and the authorities state that it resulted in the placing of orders amounting close on to $10,000,000, thus indicating the importance of the Trade Fair for which arrangements are now being made. Canadian manufacturers who are desirous of securing exhibit space or more complete particulars should communicate with the following British government trade commissioners:—G. T. Milne 367 Beaver Hall Square, Montreal; F. W. Field, 260 Confederation Life Bldg., Toronto; or L. B. Beale, 610 Electric Railway Chambers, Winnipeg.

MORE DISCUSSION ON LEGISLATION

WHEN is an engineer not an engineer? That seemed to be the main question at a special meeting of the Toronto branch of the Engineering Institute of Canada, held June 12th, at the Engineers' Club, Toronto. The answer, claimed the younger members of the branch, is, "When he is an assistant engineer."

The meeting was called by special request of the younger members of the branch, to continue the discussion on the draft of the proposed legislation which will be sought by the Engineering Institute in order to close or partially close the engineering profession.

Clause 7i, dealing with assistants working under professional engineers, was the one to which objection was taken by the younger members. J. C. Krumm thought that if the bill were passed in its present form it would mean that no engineers other than chiefs of departments would be considered as professional engineers.

H. A. Goldman strongly defended the professional standing of salaried engineers who report to superiors, and complained regarding the injustice the bill would do to the professional standing of these men.

Frank Barber thought that the bill in its present form does not exclude all salaried engineers from being considered as professional engineers.

Willis Chipman read several letters from other members of the legislation committee stating that undergraduates cannot expect to be considered as professional engineers immediately upon graduation. Among others who took part in the discussion were E. T. Wilkie, F. B. Goedike, C. S. Gzowski and Major H. N. Gzowski.

It was moved by J. C. Krumm and seconded by Frank Barber that a committee of five members be appointed to consider carefully the draft bill in detail and to submit recommendations to a general meeting to be called at a later date. This motion was carried and the following members were appointed to special committee:—

Willis Chipman (convenor), Prof. H. E. T. Haultain, Thomas Hogg, J. C. Krumm and H. A. Goldman. This committee will meet weekly until its work has been completed.

ACCELERATION OF CONCRETE HARDENING

AS the result of some experiments made by the U.S. Bureau of Standards to develop a method to accelerate the rate at which concrete increases in strength with age, it was found that the addition of small quantities of calcium chloride to the mixing water gave the most effective results. A comprehensive series of tests was inaugurated to determine further the amount of acceleration in the strength of concrete obtained in this manner, and to study the effect of such additions on the durability of concrete and the effect of the addition of this salt on the liability to corrosion of iron or steel embedded in mortar or concrete. The results to date indicate that in concrete at the age of two or three days the addition of calcium chloride up to 10 per cent. by weight of water to the mixing water results in an increase of strength over similar concrete gauged with plain water, of from 30 to 100 per cent., the best results being obtained when the gauging water contains from 4 to 6 per cent. of calcium chloride.

Compressive strength tests of concretes gauged with water containing up to 10 per cent. of calcium chloride, at the age of one year, give no indication that the addition of this salt has had deleterious effect on the durability of the concrete.

At a recent meeting of the Engineering Council of the United States, Chairman Loweth, of the Committee on International Affiliation of Engineers, presented a verbal report to the effect that a few weeks previously he had visited Vancouver and met five or six prominent engineers, who were receptive to proposals for activities that might be of common interest.

MOVING 60-FT. OIL STORAGE TANKS 150 MILES BY WATER

By A. J. T. Taylor
Manging-Director, Taylor Engineering Co., Ltd.

EARLY in 1918 the Powell River Co., operating a very large paper mill at Powell River, B.C., were faced with the necessity of immediately providing additional fuel oil storage capacity of 45,000 barrels to accommodate the last cargo of fuel oil that they expected to be able to obtain from the California fields during the duration of the war.

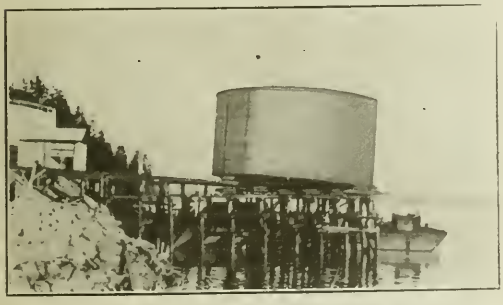
The matter of providing this storage was placed in the hands of the Taylor Engineering Co., Ltd., of Vancouver, who upon investigation found that not only was the price of steel tank plate very high, but it was impossible to obtain the necessary plates within the desired time.

Tanks in Original Position at Bamberton

Concrete storage tanks were considered, and it was found that a tank of the capacity of 45,000 barrels would have cost in the neighborhood of $60,000.

The situation appeared almost hopeless until it was discovered that the Associated Portland Cement Co., at Bamberton, B.C., had three 15,000 barrel storage tanks that they were not using, and were willing to sell. These were purchased on the foundations, as they stood at Bamberton, for approximately $24,000.

The question of transferring these tanks from Bamberton to Powell River was next tackled ,and it was at first thought that the only way of doing this would be the usual method of cutting the tanks down and re-erecting them. It was then found that, due to the large program of the Imperial Munitions Board for the construction of wooden and steel

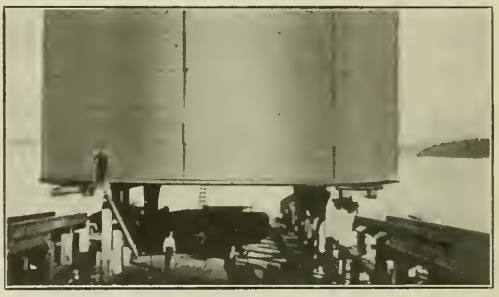


Scow Moving into Position Under Tank

vessels in the neighborhood of Vancouver, there were only three or four boiler makers available, and only one of these who had any experience in tank work. In other words, it was practically impossible to ge an adequate supply of labor to cut down and re-erect these tanks.

First Tank Loaded and Leaving Bamberton

Therefore, it was determined to move the tanks in one piece after calculations had been made to determine the stability of each tank when mounted on a 30-ft. by 40-ft. scow. Two lines of piles were driven at Bamberton opposite the point at which the tanks were located. The tanks were lifted from their foundations by means of jacks, and set out over the water at a sufficient distance above the water so that the scow could be run in between the lines of piles at low tide, and after the tide came up, each tank would settle



Tank at Foot of Incline, Powell River

on the scow and the scow and tank be pulled free of the trestles.

It was thought desirable to brace the tanks internally to eliminate so far as possible the strain that they would be subjected to in their journey from Bamberton to Powell River, and the method finally adopted was to drill a 2-in. hole in the centre of the bottom of each tank, and in this hole mount a shackle from which was set up a series of turnbuckle guys from the top edge of the tank to the shackle, the structure of each tank being depended upon to prevent the sides being pulled in by the strain on the turnbuckles.

Ready to Haul up Incline at Powell River

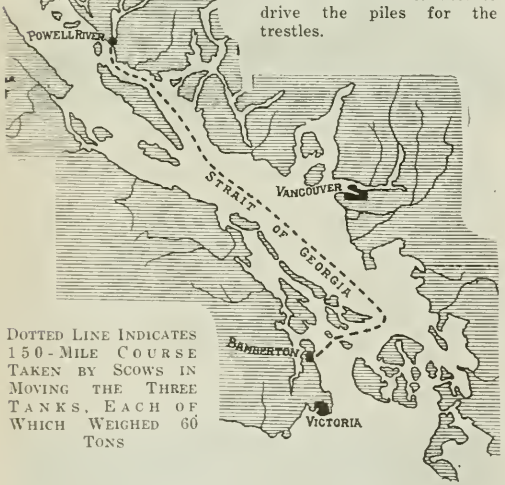
Each tank, after it was floated onto a scow, was towed approximately 150 miles to Powell River, at which point four lines were driven, and between each pair of lines a space was left that would admit the scow. From the landing platform double tracks were extended up approximately 800

THE THREE TANKS IN FINAL POSITION AT POWELL RIVER

ft. to the final location for the tanks, these tracks being spaced so as to accommodate standard-gauge tracks.

The scow was floated between the trestles, which were at such a height so that at high tide there was ample space between the bottom of the tank, as it projected on each side of the scow, to enable the railway trucks to be run underneath, and as the tide lowered it left each tank supported on the trucks.

The tank was then hauled up the inclined runway to the foundation that had been prepared by means of a 7 by 10 double-drum engine that was installed on the pile driver that had been used to drive the piles for the trestles.



DOTTED LINE INDICATES 150-MILE COURSE TAKEN BY SCOWS IN MOVING THE THREE TANKS, EACH OF WHICH WEIGHED 60 TONS

The three tanks were unloaded and the job completed within thirty days at a total cost of $14,000, which was nearly $5,000 lower than the lowest tender had received from local iron works for cutting down and re-erecting the tanks. The total cost to the Powell River Co. of the three tanks complete was $38,650.

The tanks when loaded on their final foundations and tested, were found to be absolutely free from leaks,—evidence that they were not seriously strained in the moving operation.

AGENTS FOR ROBERTS FILTER MFG. CO.

ANNOUNCEMENT has been made of the appointment of E. J. Philip & Sons, Hamilton Trust Bldg., Toronto, as agents for Ontario for the Roberts Filter Mfg. Co., of Darby, Pa. Mr. Philip returned to Toronto last February after having spent two years in Porto Rico as resident engineer for the Roberts Filter Mfg. Co. on American government business in connection with emergency water supplies. Previous to his connection with the Roberts Co., Mr. Philip was manager at Brockville, Ont., of the gas, electric light and waterworks departments, and had previously held a similar position at Kitchener, Ont., where for seven and a half years he had been manager of the gas, electric light and street railway services. Prior to moving to Kitchener, he spent seven years as mechanical and electrical engineer for the T. Eaton Co., Ltd., Toronto. The Roberts Co. have been represented in Canada for some years past by Smiley Bros., of Edmonton, who will continue to have the agency for Albert and Saskatchewan, and by Arsenault & Plamondon, of Montreal, who will continue as the Quebec representatives.

PUBLICATIONS RECEIVED

TRAUTWINE, THE CIVIL ENGINEER'S POCKET BOOK.—First issue of the twentieth edition, published by the Trautwine Co., 257 South Fourth St., Philadelphia. Canadian selling agents, Renouf Publishing Co., Montreal. 1,528 pages, 4 by 6½ ins., flexible cover. Price, $5 net. This new edition of this well-known and popular work was reviewed in advance in some detail in *The Canadian Engineer* for April 10th, 1919.

The Dominion Tar and Chemical Co., Ltd., have moved their Toronto office from the Bank of Hamilton Building to larger premises at 400 McKinnon Building, Melinda St. Their new telephone number is Adelaide 3827.

At the good roads convention in Quebec, T. Harry Jones, city engineer of Brantford, Ont., discussed Mr. Breed's paper on the use of concrete in roads, bridges and culverts. Referring to the tests described by Mr. Breed (see *The Canadian Engineer* for May 29th, 1919), Mr. Jones said that they were most valuable in concrete road work from a pioneer standpoint, as the machine had the same effect on the pavement as the caulks of horses' shoes. If proper methods are used in their construction, said Mr. Jones, there is no doubt about the absolute satisfaction that will be given by concrete roads. He inquired from Mr. Breed why fourteen days should be stated as the period which should be allowed to elapse before a newly completed concrete road is opened to traffic. Mr. Jones said that he could understand why seven days should be allowed to elapse, but he wondered whether there was any scientific basis upon which fourteen days were fixed. He had known engineers who claimed that two days were sufficient. Mr. Jones also referred to the longitudinal joints, which he said he had tried and found satisfactory. In replying, Mr. Breed said that he did not know of any scientific data upon which the fourteen day period was based. Some engineers say that seven days are sufficient, while others say that it is not safe to open the road to traffic even in fourteen days. In order to harden the concrete more rapidly, a 4% solution of calcium chloride had been used, thus increasing the strength of the structure, and after seven days with this treatment, the increase in strength of the pavement was approximately 20%. Mr. Breed called attention to the fact that longitudinal joints should be continued up into the new material when resurfacing a road. In regard to transverse joints, he said that New York had spaced them at various intervals from 25 to 150 ft. and that no definite conclusions had yet been arrived at as to the best spacing, as the state had been experimenting along these lines only three or four years and it was impossible yet to arrive at any definite conclusion.

WATER WORKS SITUATION AT TORONTO

Consumption is Increasing and Additional Filtration and Pumping Capacity May Soon be Required—Works Commissioner Favors New Construction

DESPITE the new ver Mehr filtration plant, the city of Toronto is said to have insufficient filtration capacity for its present requirements. R. C. Harris, commissioner of works, has admitted that a certain amount of raw water had to be let through the mains recently because the combined capacity of the old slow sand filter plant and the new ver Mehr rapid sand plant was insufficient.

The slow sand plant is rated at 48-million gallons daily capacity and the ver Mehr plant at 60-million, so that on paper the city has 108-million gallons daily capacity, but it is only on paper, as the slow sand plant cannot filter with maximum efficiency more than 36-million gallons daily, as part of the plant is always "out" for cleaning, while the ver Mehr plant has had one or more units out of commission most of the time for one cause or another.

Difficulty with the Throats

The chief difficulty in connection with the ver Mehr plant has been the throats on the sand washers, which have been cut rapidly by the sand and water, and which have had to be constantly repaired and replaced. It is understood, however, that a heat treatment has been devised that is producing satisfactory results in these throats, and that the ones produced by this new process are lasting much longer. All of the units are now being equipped with these heat-treated throats.

Upon inspection of the plant a couple of weeks ago, *The Canadian Engineer* found that three of the ten units were out of commission. One was out on account of repairs to the throats, and another for other necessary repairs. In the third unit all of the sand had been removed and a layer of fine graded gravel, mixed 1 to 15 with portland cement, was being laid over the coarser gravel. It was stated that this was being done as an experiment to see whether it would hold down the coarser gravel, as trouble had been experienced during the back-washing with gravel being shot up into the sand.

Referring to the general situation, Works Commissioner Harris is reported to have said: "I can only say what I have said for years, and that is that the situation will never be satisfactory until we have a duplicate plant."

When he presented his plans in 1913, for a new filtration and pumping plant to be located at the east city limits (Victoria Park), the cost mentioned was $6,033,700, including nearly $2,400,000 for 32 miles of distribution mains. What the cost would be to-day is not known, but it would certainly be much higher. Some of the new mains have already been constructed, however.

In the two filter plants at the Island, Toronto has invested nearly $2,000,000.

Pumping Station Nearing Capacity

The main pumping plant is also nearing its capacity. The capacity of the steam pumps at the John St. station is 102-million gallons, daily, but on account of repairs, etc., the average pumping capacity is often not over 78-million gallons. There are electrically-driven standby pumps of 88-million gallons capacity. As the maximum consumption has reached the rate of 90-million gallons daily (for a portion of a day only), part of this must be supplied by the reservoir. The consumption during the recent very hot weather was at times 78-million gallons daily.

As all Toronto's water, whether filtered or raw, is effectively chlorinated, there is no danger of an epidemic, says the health department. In fact the department announces a new low record in typhoid mortality in Toronto, there having been only three deaths from that disease during the present calendar year, and two of those cases originated outside of the city. This is largely due to the fact that no expense is spared in treating the water whenever it is in a dangerous condition. When there is an east wind, endangering the supply on account of the sewage outfalls, three grains of alum per gallon of water are used at the new filtration plant, and the amount of chlorine fed at John St. is also increased.

The alum consumption for the month of May averaged over two grains per gallon. For a time chlorination was tried at the Island, ahead of filtration, as well as after filtration at John St., and it was thought that by chlorination ahead of filtration the amount of alum required would be reduced. Although this was found to be the case, the Health Department objected to the two chlorinating plants on account of division of responsibility, and the Island plant was recently removed and the chlorinating again centred entirely at John St.

The only chlorinating plant at Toronto Island now is a small unit for chlorinating the supply for the Island itself, and it is connected into the suction of the pump that supplies the services on the Island.

It is rumoured that before asking any further money for the extension of filter plants or the construction of new pumping stations, the Works Commissioner will eliminate all underground leaks by means of thorough pitometer surveys, and that he will also recommend the reduction of waste in houses and industrial establishments by the metering of all services, both domestic and industrial. It is well-known that nearly all of the city officials are keenly in favor of meters and also of constant surveys for underground and other leaks. A few years ago a very successful pitometer survey was conducted in Toronto, and this work is most likely to be taken up again in the near future, as the daily average consumption per capita is about 120 gallons and has at times probably exceeded 150 gallons.

PROGRESS BY ENGINEERING COUNCIL'S COMPENSATION COMMITTEE

REPORTING at the recent regular meeting of the United States Engineering Council, the committee on classification and compensation of engineers presented the following analysis of the situation:—

"In attempting to formulate standard rates of compensation for professional engineers, the first task is to find what rates are actually in force, especially in those fields where attempts at standardization have been made. The second task is to inquire what adjustment should be made to correspond to the great change which has taken place in the cost of living, or, in other words, in the value of the dollar. How great this change has been during the past 20 years is realized by few. Fortunately, an accurate determination is available in the statistical records of average prices which for many years have been gathered and published by leading commercial organizations.

"A record of average prices of the necessaries of life kept by R. G. Dun & Co., shows that prices have increased continuously for 22 years. A certain quantity of staple necessaries could have been purchased July 1st, 1897, for $72.45. By January 1st, 1905, the same quantity cost $100.32. On January 1st, 1914, before the outbreak of the war, the cost had risen to $124.53; May 1st, 1917, to $208.43, and October 1st, 1918, to the maximum of $233.23.

"This enormous increase in prices of the necessaries of life has been accompanied by an increase in wages, especially among workers organized in unions which had the power to compel attention to their demands. In the unskilled labor market the relations of supply and demand raised wages during the war to points in some cases exceeding the increase in the cost of living. No such increase has taken place in the compensation of salaried workers in the professions. It has been assumed that these workers, living in a different social environment, had a margin of compensation sufficient to enable them to meet the increased cost of living. This assumption is not justified by the facts. Where salaries have been increased during the past three years, there are few cases in which the increase has been at all commensurate with the increase in prices of the necessaries of life, which the salaried worker, like the wage worker, has to purchase. That this is a correct statement

is amply proved by many direct comparisons which have been made of the wages of the workers in various skilled trades and the salaries of the rank and file of technical and professional workers.

"There is little doubt that an unprejudiced investigation would show that a large proportion of the salaried workers in professional occupations during the past three years have been unable to pay their living expenses from their earnings and have been obliged to rely on income from property owned or to use up savings of other years in order to maintain themselves.

Present Prices Here to Stay

"A serious question is whether the present scale of prices is here to stay. There has been a general belief that with the coming of peace and the resumption of productive industries a heavy fall would occur. It has been assumed that the salaried worker would have to wait for this so that he could again live within his income. It now appears, however, to be the opinion of many financiers and economists that the present high prices of necessaries are likely to continue for a long time, probably for several years. The salary of $2,000 a year which a man received from 1902 to 1905, will now buy less than $1,000 worth of necessaries. This has been the case for two years. If this is to continue for two, three or four years to come, then surely the salaried worker, in a professional or any other occupation, has an equitable claim to have his compensation brought back in purchasing power to where it was fifteen years ago.

A Gross Deception

"There is another aspect of the compensation of the professional worker which has been frequently misunderstood, but which, with present knowledge, ought no longer to deceive. The pay of professional engineers has for many years been influenced by the idea that a young man in the earlier years of his work should expect moderate compensation because of the future to which he might look forward. In Great Britain this idea found expression for many years in the custom of the young engineer paying a premium during a number of years' service in order to learn the business. There was justification for this idea during the period when the development of engineering was so rapid that a large proportion of the men who were turned out from the few engineering schools or the engineering workshops were able eventually to rise to positions of large responsibility and importance, commanding high salaries.

"That condition has been altered. Of the men who begin technical engineering work to-day, only a very few selected ones can rise to positions of responsibility commanding high salaries. The rank and file must inevitably be ten times as numerous as the captains and lieutenants, and a hundred times as many as the majors and generals.

"The man of exceptional ability, indeed, may find it worth his while to work for low compensation because of the future awaiting him. But to hold up to the rank and file of technical workers the idea that they can afford to work for insufficient salaries for the sake of some future high position, which they have not one chance in twenty or fifty of attaining, is a gross deception.

In Public Interest that Engineers be Well Paid

"The committee believes, therefore, that in adopting standards for the compensation of workers in all technical fields, due consideration must be given to the great increase in the cost of living which has taken place. The dollar of salary must be considered with regard to what it will purchase to-day and is likely to purchase next year, and not with regard to the value of the dollar ten or fifteen years ago.

"This increase in compensation is necessary, not merely as a matter of justice to the engineer, but in order that engineering work may be maintained on the plane that it must be to secure economical and efficient work. Not only the leaders but the rank and file of technical workers often have it in their power largely to affect the cost of the work in their charge by the quality of the effort they exert."

WATER EXPECTANCY IN TUNNELS, MINES AND DEEP WELLS IN HOMOGENEOUS ROCKS*

By Robert E. Horton

IN planning deep subsurface structures such as tunnels and mines, it is desirable to form some idea in advance as to the amount of water which will probably be encountered and will require removal. Isolated test shafts are costly, and may not show average conditions. It is desirable to supplement such special data by considerations based on general experience as to the yield of underground water under similar conditions.

Data can generally be secured as to the yield of shallow or surface wells overlying the region where the underground structure is to be made. Such data have been published concerning many conditions and kinds of rock as to the average and usual range of yields of surface wells under different conditions.

It is the purpose here to present a method and formula by which data obtained from surface wells can be applied, under suitable conditions, to the estimation of the amount of water which it may reasonably be expected will be encountered in any deep excavation.

The method is limited to cases where the bed rock is somewhat uniform in character throughout all depths from the rock floor down to the bottom of the tunnel or other structure. For example, the method will apply to the estimation of probable water in a tunnel in granite, which extends to the surface, but will not apply to a tunnel in deep-seated granite overlain by thick beds of sedimentary rocks.

Without giving details it may be said that there are physical reasons, well confirmed by statistics and experience, showing that the frequency and water-carrying capacity of fissures, joint openings and solution channels in rocks decreases rapidly as the depth increases.

Assuming, for simplicity, and as fairly representing experience, that the water-yielding capacity of a given kind of rock varies inversely as the depth, and that q is the maximum yield per sq. ft. of surface at a depth 0 to 1 ft. below the water table. The quantity q corresponds to Slichter's "transmission constant" and its value can be determined from the measured yield of shallow wells in the given location and kind of rock. Then the yield per sq. ft. of surface at a depth h below the surface of the water table may be expressed by the equation

$$q_h = q'h \qquad (1)$$

The total yield from one side only of a vertical surface one foot wide intersecting the water bearing rock from a depth h_1 to a depth h_2 will be to

$$Q' = q_1 \int_{h_1}^{h_2} dh\ h \qquad (2)$$

If p is the ratio of the perimeter of a tunnel to its height, or the ratio of the perimeter of a well to its diameter, then letting Q_1 equal PQ', where Q_1 is the total yield of a horizontal tunnel per ft. of length, or the total yield of a well between any chosen depths per ft. diameter, there follows by integrating

$$Q_1 = q_1 p\ (\log_e h_2 - \log_e h_1) \qquad (3)$$

If it is desired to determine the total yield of a well from surface to bottom, h_1 should be taken as unity to correspond to the conditions assumed in fixing the value of q_1.

As a practical example, statistics gathered by E. E. Ellis, M. L. Fuller and others show the average yield for numerous shallow wells, on steep, rocky areas, in granitic gneiss and schist of southeastern New York and Connecticut, to be about 4 gals. per min. for 6 in. wells with an average depth in rock below the water table of about 150 ft. The perimeter of a 6-in. well is 1.54 ft. and the corresponding rate of yield for a flat surface 1 ft. wide and 150 ft. deep would be 2.60 gals. per min. Solving (3) for q_1 under these conditions:—

$$q_1 = 2.6 \log_e 150 = 0.52 \text{ gals. per min.}$$

*From the Journal of the American Water Works Association.

It should be noted that only wells with little cover of sand or other unconsolidated material have been considered in selecting the value of Q_1 to determine q_1. Shallow wells in rock but with deep cover of loose material often receive much of their supply from above the rock, and may indicate water quantities in excess of the transmission capacity of the rock itself, even at the surface where it is most fissured.

Let it be required to determine the amount of water that will probably be encountered in a tunnel 15 ft. high and with 60 ft. perimeter, at an average bottom depth of 250 ft. below water table in granitic gneiss and schist, the length of the tunnel in rock being 11,000 ft. Using the value of q_1 above determined, and solving (3)

$$Q_1 = 0.52 \times 4\ (\log_e 250 - \log_e 235) =$$

0.135 gals. per min. per ft. of tunnel.

Let Q equal the total infiltration to the tunnel, the length being L. Then $Q = Q_1 L = 1485$ gals. per min. This indicates that provision should be made to dispose of 1485 gals. per min., or something over 2,000,000 gals. per day.

Experience in constructing the tunnel for which data are above given showed an average yield for some time of 1,000,000 gals. per day, and larger yields at times, approaching the amount above calculated.

Like most hydrologic methods and formulas, this one is not infallible, and its application requires intelligent discrimination in selecting surface-well data to determine q_1. It is intended to apply to fissured rocks such as granites, trap, basalt, gneisses, schists, and sometimes limestones and dolomites. It is possible that a large water vein may be encountered which will greatly increase the yield, but the probability of this decreases with increased depth.

In the case of unconsolidated materials and sandstones, the water transmission capacity may decrease little or none with increased depth, and formula (3) does not apply. The quantity of water obtainable from such deposits by means of wells, tunnels and infiltration galleries can be calculated by existing formulas given in various books on water supply.

In the case of shales, experience shows that the water-bearing fissures decrease very rapidly with increased depth, in fact little or no water is generally obtained in dense shales at depths more than 50 to 100 ft. below the rock floor. Observations by the author in the case of many deep wells in Hudson River shale as to the relation of depth to yield is fairly represented by the formula

$$Q_1 = 2 q_1 p\ [(1/h_1) - (1/h_2)] \quad \ldots\ldots\ldots\ldots\ldots\ldots\ (4)$$

This is derived on the assumption that both the number and size of connected fissures in shale decrease as the depth increases, or that the transmission capacity per unit of surface varies inversely as the square of the depth. For example, if a 6-in. well extending 20 ft. below water table in shale yields 6 gals. per min., then solving for $q_1 p$ in (4) by taking $h_1 = 1$ and $h_2 = 20$

$$q_1 p = 6/2\ (1 - 1/20) = 3.15$$

To find how much the yield of this well will be increased by extending it to a depth of 100 ft., we have from (4)

$$Q_1 = 6.30 \times (1 - 1/100) = 6.24$$

The yield of the well would be increased ¼ gal. per min. by extending it from 20 to 100 ft. depth.

The formula indicates that half the water obtainable will be found in the first foot of depth in shale rocks.

This result is certainly of the right order, since experience shows that nearly all the water obtainable in Hudson River shale is often found within 5 ft. below rock surface. A number of wells to depths of over 1,000 feet in shale in the vicinity of Albany, N.Y., afford their entire yield very near the surface and refute the popular belief that water can always be found in abundance if only a well is drilled deep enough.

Formula (3) can be applied in a manner similar to (4) to determining the probable increase of yield with depth for wells in granite, etc., and indicates little expectancy of increased yield at depths exceeding a few hundred feet, which also is verified by experience.

Formulas (3) and (4) are intended more especially for application to tunnels and mines rather than to wells, since the surface area of ground water interception in the case of the former is much larger and will generally approximate average conditions more closely than for isolated wells.

EFFECT OF THE WAR UPON WATER WORKS' REVENUES AND EXPENSES*

By Leonard Metcalf
Consulting Engineer, Boston, Mass.

THE situation with regard to the water works of the United States is probably fairly shown by the accompanying comparative records of about 50 plants with aggregate annual revenue of about $35,000,000 and supplying a total population of upwards of 9,000,000 persons, or nearly 9% of the entire population of the United States. The data for 1914-17, were presented to the association a year ago by its committee on war burdens of water works. The 1918 figures have been collected and added by the writer. These records indicate that:—

1. The annual revenues with such increase in rate schedules as were granted by the regulatory authorities and put into effect by the plants, have increased at an average rate of approximately 7% per annum, slightly less than a normal amount.

2. The operating expenses, including taxes where taxes are paid, and excluding them where none is paid, have increased over the year 1915, abnormally, by 13% in the year 1916, 33% in the year 1917, and 52% in the year 1918.

3. The net (operating) revenues applicable to depreciation, interest, dividends and surplus, have substantially stood still since the year 1915.

Table I.—Comparative Water Works Revenue and Expense, 1914-1918, in Percentages of 1915

Group.	1914.	1915.	1916.	1917.	1918.
Percentage Gross Annual Revenue.					
Eastern	95.7	100	110.1	112.8	120.6
Central	98.3	100	109.1	111.4	126.4
Southern	97.7	100	107.5	120.3	126.3
Western	101.7	100	107.3	109.5	117.5
Average	98.3	100	108.5	113.5	122.7
Percentage Operating Expenses, Including Taxes.					
Eastern	99.7	100	121.9	141.1	149.7
Central	100.9	100	109.3	137.3	162.3
Southern	97.0	100	109.7	134.6	166.9
Western	98.6	100	109.9	117.4	128.0
Average	99.0	100	112.7	132.6	151.5
Net Revenue Applicable to Depreciation, Interest, Dividends and Surplus.					
Eastern	90.9	100	103.0	90.4	105.8
Central	97.3	100	110.0	98.5	106.6
Southern	97.9	100	96.3	104.0	89.1
Western	103.6	100	104.3	105.3	114.4
Average	97.4	100	103.4	99.6	104.0

The average increase in population in this country has been at the rate of approximately 1.9%, compounded annually, and of the cities supplied by these 50 typical water works, about 3.1%.

The net revenue of water works usually increases at the rate of from 4% to 5%, compounded annually. Yet the total increase in the three-year period from 1915 to 1918, is but 4%, against a normal amount of from 12% to 15%, in spite of increases granted by the commissions.

The records gathered indicate further that the increases in rates granted to water works by the commissions seem to have amounted on the average to about 10%, serving thus to decrease the loss in net revenue in the year 1918, from 20%, more or less, to 10% or thereabouts. If this inference is sound, the loss in operation was divided equally between the works and their consumers.

It is clear, however, that the burden of increased operating expenses, plus the interest upon the new investment put into these properties during the war period, has been *borne by their owners*, in larger measure than by the public, except in the case of publicly owned works.

Unskilled Labor Costs, in cents per hour (see Table II.) did not generally feel the influence of the war until the middle of the year 1916. As compared with pre-war conditions,

*Read last month at the Buffalo Convention of the American Water Works Association.

TABLE II.—INCREASE IN COST OF LABOR AND MATERIALS TO WATER WORKS IN THE UNITED STATES, AS REPORTED TO THE EXECUTIVE COMMITTEE OF THE AMERICAN WATER WORKS ASSOCIATION, MAY, 1918, AND REVISED, APRIL, 1919

Item.	Number of Records	Prices per Unit				Per Cent. Increase over 1915			Year 1918		
		1915	1916	1917	3 Mos. 1918	1916	1917	3 Mos. 1918	No. of Records	Unit Price	Per Cent. Increase Over 1915
Unskilled labor* in cents per hour:

*Note. It was generally reported that there has been also a marked decrease in efficiency of labor since 1914, variously estimated at between 20% and 50%; and that the increase in wages paid to labor by water-works had not kept pace with contract prices, owing probably to the advantage of continuity of service.

†See "Journal of Industrial and Engineering Chemistry." Note that 1915 price was an advance of 34% over the 1914 average price before the advances listed went into effect.

reflected by the prices prevailing in 1915, they increased one-eighth in 1916, one-fourth in 1917, and nearly three-fourths in 1918. The increase was felt most markedly in the south and upon the eastern seaboard, being nearly doubled in the first, and increased by three-fourths in the latter district. The wages paid upon the Pacific coast before the war, which were much higher, have advanced relatively less than elsewhere, so that at the present time the eastern and western unskilled labor prices are about the same. Thus the average rate in the western group increased from 27c. per hour in 1915, to 42c. in 1918; while the southern rate increased from 18c. to 34c.; the central group from 22c. to 37c.; and the eastern group from 23c. to 40c.

In spite of the general business uncertainty and resulting depression, wages paid to unskilled labor, by water works in the vicinity of Boston, have advanced from approximately 41c. per hour, under date of September 14th, 1918, to approximately 46c. per hour in April, 1919, without allowance for the effect of vacations and holidays under pay, granted by some works. Present (June, 1919) conditions give little if any indication of reduction in prices this year, or hope for any marked reduction in the future.

Cast-iron pipe prices (Table II.) which had about trebled at their maximum point, have now receded to about twice pre-war figures. *Valves, hydrants and pumps*, which had more than doubled in price, are now to be had at an advance of something over seven-eighths of pre-war prices. *Coal and fuel oil prices*, which more than doubled, have receded somewhat. *Chemicals* used in the purification of water, which, by reason of outstanding contracts showed an average advance of but one-third, though the market price had increased approximately three-fourths, have decreased so that the present excess cost is about one-half over pre-war prices.

Future prices—Engineers prefer the role of interpreter of facts to that of prophet. It is desirable, however, to note here probable future price tendencies. First, with respect to unskilled labor, no marked change is to be looked for; and with respect to the rates paid to water works employees, it is believed that the prices now paid are likely to continue in most cases, and to increase rather than to decrease in the remaining cases. Unless Bolshevism runs its course in this country, or industrial depression should follow the war—neither of which seems likely—an active demand for labor is to be looked for in the near future. It is to be remembered that, despite the war, the population of this country has been increasing at a rapid rate. Immigration has been at a standstill, and in the light of home demand for labor abroad, does not seem likely to be active for some time to come. Many employers, contractors and labor leaders believe that in the not distant future this country is sure to feel the competition for available labor and that this will stimulate yet higher wage scales.

Necessary Improvements Should Go Forward

Second, with respect to materials of construction, there is greater hope for relief. Nevertheless, no substantial reduction in the price of cast-iron pipe, valves and hydrants seems likely for the present year, and but a gradual reduction is to be looked for in the future. In spite of the increased facilities for production, the labor, transportation and money conditions involved seem likely to make themselves adversely felt for some time, and the losses resulting from the war seem likely to be permanent.

Third, the materials of operation—coal, fuel oil, and chemicals—do not appear likely to decline markedly in cost, and such tendency toward decrease as there may be will probably cause the making of short-time, rather than long-time, contracts for such supplies.

The Future—The conclusion to be drawn from the present physical and financial condition of water works in the United States seems clearly to be that *necessary improvements should go forward as rapidly as possible.* It is desirable to restore public confidence and further the government's wise wish to give employment to idle labor. More important yet, *improvements are seriously needed to restore our normal high standard of water service, to safeguard adequately the public health.*

While city officials and water works men are hesitating, the large manufacturing interests, dominated by shrewd, farsighted business men, are going ahead with their construction work, with their plant extensions and housing projects, confident that postponement will at best offset increased cost in small measure; will probably involve loss in service or profit far exceeding any saving in construction cost; and at worst will involve yet higher costs, coupled with increasing difficulties due to a vanishing labor surplus.

The public is far more vitally interested in thoroughly good and adequate present service than in any probable saving to be effected by delaying construction to a later date, in anticipation of further, more or less problematical, decline in costs.

CEMENTS PRODUCING QUICK-HARDENING CONCRETE*

By P. H. Bates

IN the course of the investigations which the Pittsburgh Branch of the Bureau of Standards has been conducting dealing with the various problems relating to Portland cement, there have been made a number of cements which are characterized by a very high early strength. This is developed when the cements are used either as mortars or concretes. These cements have been made in a manner differing in no wise from that used in the manufacture of Portland cement. However, the composition of the materials entering into their manufacture was decidedly different, limestone and calcined alumina having been used in some of the raw mixes, and in others the alumina was replaced in part by kaolin or bauxite in order to determine the effect of impurities on their general properties. While such materials have been the subject of research by others, especially Spackman, their property of developing very high early strengths is not generally known. It is believed that the data presented in this paper, especially that dealing with the concrete, are the first of their kind ever presented.

The data dealing with the aluminates are augmented by some obtained in making concrete from "Sorel cement" which, as is generally known, is light calcined magnesite guaged with magnesium chloride. It has been unofficially reported that during the recent war the enemy used a concrete made of such a cement for "setting up" their large guns. As it obtains the greater part of its strength within 24 hours, and as this strength equals that obtained by a Portland cement at the end of two or three weeks, the possibility of using it becomes very attractive. The data herewith presented were obtained in making a limited number of concretes, but it is believed that such data, in so far as they relate to concretes, have never before been presented.

Concrete Made with Sorel Cement

It is not intended to go into any great detail in presenting these data. For this reason, the nature and general properties of this cement will be touched upon but briefly. The fact that magnesium oxide, when mixed with a solution of magnesium chloride, will harden was possibly first known by Sorel in 1853. From him it has at least taken its more common name. The physical character of the oxide and the permissible impurities, the concentration of the chloride and its permissible impurities, and the nature of the hardened material have all been the subject of extended investigations. Briefly, the results show that the purer the ingredients, both oxide and chloride, the better the resulting cement. The oxide must be produced by burning a carbonate to such a temperature only that a plastic mass results when it is gauged with water. Too high a temperature of calcination produces a very inferior oxide. The nature of the hardening has never been satisfactorily solved. For a late investigation and discussion of these points and a satisfactory bibliography, reference should be made to Bulletin No. 879 of the University of Wisconsin.

At the present time this cement is used in rather large quantities for making a resilient flooring which is usually referred to as "composition flooring." When so used the aggregate is composed of asbestos fibre, sawdust, inert finely ground filler as sand and coloring matter. This flooring is widely used in a monolithic form in office buildings, passenger and subway cars and interior ship decks. Recently a mortar very similar in nature to the above, excepting the omission of the fibrous material, has been rather successfully used as a stucco.

The magnesia used in the present investigation was made from magnesite mined in California. It was a mixture of two shipments from two manufacturers of flooring. Both had given satisfactory results when used in flooring mixes. No data are at hand which would enable one familiar with portland cement to form an idea of the relative strengths which these would develop in the usual small briquette or compression specimen. The small specimens made were of a flooring composition and as such were composed of 50% magnesia, 12% asbestos, 10% sawdust, 22% ground sand and 6% iron oxide, all by weight. This mixture when gauged with 52% of a solution of chloride having a gravity of 1.1885 (about 23° Baumé) gave the following strengths in pounds per square inch:—

Specimen.	24 Hours.	7 Days.	28 Days.	90 Days.
A				
Tension	531	841	1087	1034
Compression .	2240	3795	5330	4340
B				
Tension	576	900	935	1049
Compression .	2900	4240	5300	5370

The tension specimens were of the form specified in the A.S.T.M. Standard Specifications and Tests for Portland Cement. The compression specimens were 2 by 4-in. cylinders. All specimens were stored in air until broken.

The analyses of the mixed oxides and the chloride were as follows:—

	Oxide.	Chloride.
Silica	5.14 per cent.	....
Alumina	0.78 "	....
Iron oxide	0.57 "	....
Lime	5.69 "	0.20 per cent.
Magnesia	85.01 "	9.24 "
Ignition loss	2.86 "	....
Potassium oxide	.... "	0.17 "
Sodium oxide	.... "	0.70 "
Chlorine	.... "	16.54 "

In Table 1 is shown the strength of the concrete made from this mixed oxide and also the compressive strength developed by a Portland-cement concrete using the same proportions of the same aggregates. Notwithstanding the fact that the specific gravity of the magnesia is very close to that of Portland cement (3.08 for the magnesia and 3.12 for the cement), the volume occupied by the same weight of the two differs very materially. As the magnesia weighed but 51 lb. per cu. ft., the actual percentage by weight of the magnesia in any one concrete was decidedly less than the percentage of Portland cement. For this rea-

NOTE.—The percentage by weight of MgO in 1.0.5 1.5 and 1 : 1½ is but very little greater than the percentage by weight of Portland cement in 1: 1.0 3.0 and 1: 1½ : 2½, respectively.

* MgO proportioned by weight, making weight percentage of MgO equal weight percentage Portland cement in 1 : 1.5 : 4.5 and 1 : 2 : 4

*Paper read at the annual meeting of the American Society for Testing Materials, June 24th to 27th, 1919.

son the 1: 6 concrete was proportioned both by weight and by volume, when the magnesia was used as the cementing material. All specimens were stored in the air until broken. The gravel used was obtained from the Allegheny River and was screened between a ⅛-in. and 1½-in. screen. It contained an excessive amount of the finer sizes. The lime stone was a rather soft stone screened between the ¼-in. and 1-in. screens. The "coarse sand" aggregate was sand from the Allegheny River screened between the ⅛-in. and ¼-in. screens.

As the information sought had to do alone with early strengths, specimens were made for breaking at 24 hours,

48 hours and 7 days in the case of those made with magnesia and 48 hours and 7 days when Portland cement was used.

The results show that the Sorel-cement concretes, with but two exceptions, have a strength at 48 hours greater than that obtained by the use of Portland cement in 7 days. However, it is also seen that there is in general but little increase in the strength of the former between the 48-hour period and the 7-day period. The results obtained at all periods from the Sorel-cement concrete proportioned by weight are generally higher than those obtained when the proportioning was done by volume, regardless of what the proportions were. This clearly shows that for such a light material the proportions should be decidedly different from

those generally used with Portland cement. It would seem as if too much magnesia was used in the rich concretes and too little in the lean ones when the proportioning was carried out by volume.

Attention should be called to the difference in the manner in which the hardening of the two concretes takes place. In a Portland-cement concrete, the cement hardens by the action of the added water. During the process of hardening it is immersed in an atmosphere containing in a greater or less degree one of the essential elements of the process, that is, water, either as a liquid or vapor. On the other hand, in the Sorel-cement concrete the hardening takes place as a result of the action of the chloride on the oxide. The chloride is always essential, but any deficiency, as for instance the use of a too dilute solution, or any marked excess, is injurious. Therefore, not only the ratios between the aggregate and the magnesia must be studied, but also the ratio between the chloride and the magnesia.

While the results do show the lack of proper proportioning of both the magnesia and the chloride, yet these poorly proportioned concretes show in 24 hours as high strengths as the more properly proportioned Portland-cement concretes show in seven days. Another point should be remembered in regard to these Sorel-cement concretes, that is, they cannot be frozen. Temperatures below freezing will retard the hardening to a degree, but the freezing point of the solution is so low that no care need to taken to prevent damage from low temperatures.

Concrete Made with Calcium-Aluminate Cements

The calcium aluminates were all made in the experimental rotary kiln of the bureau. The composition of these, the constitution arranged in order of the amounts present, and the temperatures of burning are given in Table 2. The fineness and the time of setting* are given in Table 3.

With the exception of cement No. 6, no particular difficulty was encountered in burning. On account of the composition of this cement, its position in the ternary system CaO-Al_2O_3—SiO_2 was such that it was located in a field having both a low burning temperature and also one in which the orthosilicate predominate. This combination

C. S.—Stored for one quarter of period in water and the remainder in the air of the laboratory.

always produces a material which fluxes at such a temperature that the silicate on cooling reverts to the Υ form from the β form of the silicate. This reversion is manifested by the "dusting" of the clinker. It was possible to produce this particular cement only either in a decidedly underburned condition, or overburned to such a degree that it fell from the kiln in large, soft balls, which dusted on cooling unless quickly water quenched. The latter procedure of burning, without quenching, was used. Cement No. 4 was made from a very hard clinker but the latter did not show any tendency toward dusting. The clinker of the other cements was of the porous character of normal Portland clinker. Those low in iron oxide were white to yellowish in color; none of them had the glistening black appearance of Portland clinker, the darkest being a dark reddish brown. The raw materials used were calcined alumina and limestone for cements Nos. 1, 2 and 8; in Nos. 3, 4 and 5 the same materials were used but part of the alumina was replaced by a kaolin, thus reducing the alumina content of the mix but increasing the silica con-

*In carrying out the investigation presented here, no addition of SO_3 in any form was made to the cements. Work carried on at the same time as this presented here showed that such additions accelerated the time of set and caused a reduction in both the tensile and compressive strength.

tent. In No. 6 it was necessary to add some very finely ground flint, in order to secure the desired silica content, in addition to the kaolin, alumina and limestone, and iron oxide. In No. 7 bauxite, limestone and iron oxide were the raw materials.

Reference should be made to the work of Rankin, "The Ternary System CaO-Al_2O_3-SiO_2," and the author, "The Hydraulic Properties of the Calcium Aluminates," for further information in regard to the general properties of the constituents of these cements. For this present paper dealing more particularly with concrete made from them, it is not desirable to give more in regard to their properties than their reaction with water. Those aluminates indicated in Table 2, as being present in these cements, all react with water to form the hydrated form of $3CaO \cdot Al_2O_3$.* Such a reaction requires the formation of hydrated alumina. The amount of the latter will depend upon the amount of the alumina in the cement, consequently the $3CaO \cdot 5Al_2O_3$ will give the most and the $5CaO \cdot 3Al_2O_3$ the least. This hydrated alumina is, as is well known, a colloid and, when formed under the conditions indicated above, constitutes the greater part of the cementitious material of these compounds.

The higher the alumina content in any of the aluminates, the slower will be the reaction with water and consequently the slower will be the time of setting. This is shown in Table 3, but not very clearly unless studied in connection with the relative amounts of the constituents shown in Table 2. The former table shows that cement No. 3 has a slower setting time than cements Nos. 1 or 2, and also a lesser alumina content. The latter table, however, shows the presence of a large amount of silica and therefore the presence of a quantity of silicate which reduces the amount of alumina in the former cement and also retards the setting time. The two silicates present in these cements react very slowly with water, in fact the ternary compound $2\ CaO,Al_2O_3.SiO_2$ reacts so slowly that it will not form a cementing material, while the orthosilicate, $2\ CaO.SiO_2$, at the end of a year shows but little more than 5% water of hydration but a very satisfactory strength. Also a comparison of cement No. 8 with cements Nos. 1 and 2, or cement No. 7 with Nos. 5 and 6 will confirm the statement that increasing alumina content gives a slower setting cement. This has been more strikingly shown in other work carried on with the pure compounds when it was found that the tricalcium aluminate—the aluminate lowest in alumina—always gives a flash set.

With the exceptions of cements Nos. 2, 3 and 8, the burning temperatures used were either those generally used in burning Portland cement or a little lower. The temperatures used in these three exceptions were not much in excess of that infrequently used in making the latter cement and can be comparatively easily reached in a rotary kiln. One point in particular should be noted: it is impossible to produce an unsound cement unless a temperature far below that used in Portland cement practice were attempted. Slight underburning or burning at a temperature of 100° lower than that given would have produced an aluminate lower in alumina and free alumina.

Table 5 shows the strengths produced by the cements when tested in the form of a 6 by 12-in. cylinder as a 1: 1½: 4½ gravel concrete. In order that some idea may be obtained in a comparative way of their deportment as a mortar, the compressive strengths of some 1: 3 standard sand 2-in. cubes are given in Table 4. Previous work showed that, on account of the large amounts of colloidal material formed in the process of hardening, retrogression is likely to be shown by any specimens stored continuously in water or the damp closet. At certain periods, therefore, some of the specimens were removed from the water or damp closet and placed in the air of the laboratory until broken.

These two latter tables very clearly show the high 24-hour strengths. Special mention should surely be made of strengths of 2,800 to 3,100 lb. per sq. in. for a 1: 6 concrete at the end of 24 hours. The strengths of some of the 1: 3 mortars at the end of the same time is just as unusually high. The gain in strength with aging is also quite large, although maximum strength is reached at a comparatively early period. Consequently some very phenomenal strengths for either kind of a specimen are developed. A compressive strength of 8,610 lbs. per sq. in. at seven days for 1: 3 mortar or 6,010 lbs. at the same period for 1: 6 concrete are surely striking. While these results represent some of the maximum ones obtained, there are many other very exceptional high strengths shown in the tables, when these are compared with the results generally obtained with Portland cement.

[a] All specimens in these columns were stored for the first 4 months in the damp closet and for the remainder of the period in the air of the laboratory. All other specimens were stored in the damp closet for the entire period aged.
[b] Contained 3 per cent plaster

An examination of the tables shows that the maximum strength for the water or damp closet stored specimens was attained at some period previous to one year. As stated before, the quick hardening is due to a great amount of hydrated material rapidly formed. This is also in the colloidal form and will, therefore, in the presence of excess water, take up in a comparatively short time such an excess of the latter that there is a reduction in strength. It will not take up enough from air of the usual humidity to materially affect the strength. It does, however, lose water to the latter to a certain extent. It is this latter loss of water with consequent drying out of the colloid which causes the increase in strength of the water-air or damp closet-air storage over the storage in the water or damp closet alone.

It is interesting to note that in the case of the mortar specimens, cements Nos. 3, 5 and 6 developed the highest strengths by the combined method of storage at the end of the 26-week period, while the other cements developed their maximum strength by this method of storage at 28 days. Apparently, therefore, the latter were much quicker hardening than the former. Concrete specimens aged by the combined method were broken only at the one-year period. At this period, by this method of storage, maximum strength was developed by all the cements except Nos. 4 and 2. These latter developed maximum strength by damp closet storage at 7 and 28 days respectively. The continued storage of these two in the damp closet until removed to the air apparently caused such excessive hydration that subsequent drying out could not cause sufficient gain in strength to bring back the maximum strength shown at the earlier period. A shorter period of damp closet storage before the removal to the air would have been necessary in these two cases to have brought out higher

(Concluded on page 117)

*The amount of water of hydration has never been very closely determined. Some water is lost at such low temperatures, that adhering water or moisture cannot be removed without removing some combined water.

EXCELLENT REPORT ON ONTARIO TRADE

IN his first annual report on the trade of the Province of Ontario, Fred. W. Field, His Majesty's Trade Commissioner at Toronto, has covered a vast range of subjects in a most succinct and business-like manner. His report is not at all perfunctory, but to the contrary, enters into the subject in a most enthusiastic manner, and portrays real interest in the work.

While compiled entirely for the information of the British manufacturer, and presented to the British Parliament last month by command of His Majesty, the report will prove very interesting to the business men of Ontario and Canada generally. It is prefaced with a brief report on the trade of Canada and Newfoundland, owing to the fact that G. T. Milne, His Majesty's Senior Trade Commissioner in Canada, was transferred from Australia only a few months ago and had not been in Canada sufficiently long to undertake a report on general conditions.

The report is published in a booklet of 96 pages, 6 ins. by 9½ ins. The Canadian report covers financial conditions, crops, railways, minerals and mining, fisheries, lumber, immigration, scientific research, credit conditions and commercial failures, war work, iron and steel, shipbuilding and shipping program, pulp and paper, motor cars and trucks, and import trade.

The Ontario report, which forms the major portion of the booklet, covers representation of British firms in Canada, selling goods on consignment, invoices, New York agencies, designs and patterns, advertising, catalogues, moving pictures, keeping in touch with one's countrymen, visits to Ontario, engineering practice, conventions, correspondence, general conditions, crops, farm live stock, wool, minerals, lumber, fisheries, commodity prices, rubber, financial conditions, railways, canals, Toronto harbor improvements, Hydro-Electric Power Commission, road building, public works, vocational training for returned soldiers, Ontario Bulk Sales Act, Ontario Temperance Act, new lines being manufactured in Ontario, new works, munition works, national manufacturing works, banking assistance, earnings of industries, Reconstruction Association, supply of raw materials, raw materials and finished products, export trade, United States factories in Ontario, United Kingdom factories in Ontario, maintenance of industrial activity, industrial and trade organizations, iron and steel shipbuilding, lumber, pulp and paper, textiles, wool, linen, chemicals, dyes, motor cars and trucks, rubber industry, dry goods, cotton goods, gloves, metals and machinery, tools and hardware, cutlery, paints and varnishes, electric lamps, illuminating glassware, chinaware and groceries.

Appended to Mr. Field's report are brief reports from the Imperial trade correspondents at Halifax, St. John, Quebec, Winnipeg, Calgary, Victoria, Vancouver and St. John's, Nfld.; also appendices covering statistics of the pulp and paper industry for the year 1917 for the Province of Ontario, and imports into Canada for the fiscal years ended March, 1914 and 1918, compared.

In his advice to United Kingdom manufacturers seeking trade in Ontario, Mr. Field urges a larger measure of support of the Canadian representatives of British firms. The United States firms, he says, generally appoint the right man as agent and allow him adequate expenses and considerable freedom of action, whereas often a British representative is hampered by an inadequate allowance and other restrictions.

During the periods of trade depression, says Mr. Field, it is not advisable nor desirable to sever connections with a good agent as some British firms did, for example, at the outbreak of war. "A satisfactory local agent is an excellent asset," he states, "and it is a far better policy to make some arrangement to retain his services even when a dull business period arrives. This is done by our principal competitors in this market. A Toronto agency, for instance, was paid a substantial monthly retainer by a German house in New York, one of their principals, despite the fact that business was not obtainable in Ontario in their line for a considerable period. The German house wrote the Toronto firm saying: 'Even if you cannot sell goods at present, your experience and knowledge of the market are of value to us. Send us a detailed monthly report of conditions and the outlook in our line.'"

Mr. Field also urges more extensive advertising in the trade and technical journals of Canada. "With the keen competition to be met in all lines," he says, "and in a market which buys largely the goods for which publicity has helped to create a demand, it is necessary to have a continually favorable atmosphere to assist the salesman. Spasmodic advertising is of little value. A well prepared and properly conducted campaign, occupying a long period, then to be renewed, gives the greatest service."

Mr. Field has been extremely active during the first year of his office as trade commissioner, and his report reflects the great benefit that will accrue to British manufacturers and Canadian importers as a result of his further efforts. Few men are better posted than is Mr. Field on general economic and trade conditions in Canada; moreover, while working in the interests of British trade, he does not ignore the rights of Canadian manufacturers, and rarely does he encourage the importation of goods that can be satisfactorily supplied by Canadian factories.

AUTO TRUCK PERIL FOR HYDRANTS

DURING the round table discussion at the Buffalo convention of the American Water Works Association, it became very evident that a new problem has appeared for the water works engineers and superintendents of Canada and the United States, namely, the destruction of post hydrants by the heavy auto trucks that are now in general use. New York's experience has shown that the strength of the hydrants cannot be increased sufficiently to withstand the impact of a heavy auto truck skidding against it or backing into it. High pressure hydrants having a thickness of metal

of 15 16-in. have been broken, as well as the ordinary type of hydrants.

William W. Brush, deputy chief engineer of the water works department of New York City, has advised the American Water Works' Association that there are several possible answers to the problem. First, there is the flush hydrant, but this type has not yet made appreciable progress. Secondly, in Boston a change has been made in the type of post hydrant which up to date has opened with the pressure. The compression type of hydrant opening against the pressure, is being substituted. A third possible solution is to move the hydrants from the curb line to the building line, but most water works superintendents will probably leave the hydrants in their present location and assume the additional cost of maintenance.

The cost of repairing the broken hydrants is materially reduced if the standpipes are repaired by welding, which can be done successfully with modern machinery, says Mr. Brush, at a cost of from $6 to $8 per standpipe.

CEMENTS PRODUCING QUICK-HARDENING CONCRETE

(Continued from page 115)

maximum strengths. It should be remembered that the high early strengths are due entirely to rapid and more thorough hydration in the short intervals.

After the high results of the 1: 6 concretes were obtained, it was thought desirable to make some leaner concretes. Consequently a 1: 3: 9 gravel concrete was made, using certain of the cements of which there was a sufficient amount available. Even such lean concretes developed surprising strengths in several cases. This is especially true of cement No. 8 which developed a strength of 3,415 lbs. per sq. in. at 28 days and 3,980 lbs. at 90 days, and a maximum strength, by the combined storage, of 4.445 lbs. per sq. in. at one year.

In conclusion it may be stated, therefore, that the aluminates of lime, even when they contain such amounts of impurities as 10% silicia and 3% iron oxide, constitute a material which is a very valuable cementing medium when gauged with water. This particular value lies in the high early strengths which they develop. The greater the amount of the alumina present, as an aluminate of lime, the greater will be the early strength. Under certain conditions of curing there is a marked increase of strength with age, but this does not extend over a very long period of time. It also appears that if the concrete is subjected to an excess of water during curing there will be a decrease in strength. Such amounts of moisture as are usually present in the air do not materially affect the strength. It appears, therefore, that these cements might be of considerable value for certain special uses, where the principal requisite would be quick hardening.

The United States Engineering Societies' Employment Bureau received 2,891 applications for employment from December 1st, 1918, to May 1st, 1919, and placed 423 of the applicants. The total expenses from January 1st to May 31st were $5,815. The manager of the bureau states that there is every reason to believe that many more have been placed who have failed to notify the bureau, so that the average cost of placing these men probably did not greatly exceed $10.

The Ohio Electric & Controller Co., of Cleveland, Ohio, have appointed the following representatives:—Kelly Powell, Ltd., 403 McArthur Bldg., Winnipeg; Wonham Bates & Goode, Inc., Dominion Express Bldg., Montreal. They have also appointed the following export agents:—Gustave Neilson, A. S., Christiana, for Norway, Sweden and Denmark; Mitsui & Co., 65 Broadway, New York, for Japan, China, Phillipine Islands and Hawaii; Wonham Bates & Co., Inc., 17 Battery Place, New York, for Great Britain, France, Cuba and South America.

PERSONALS

Lt.-Col. Harold L. Trotter, who is a partner in the Henry Holgate firm of consulting engineers, Montreal, recently returned to Canada in command of the 11th Battalion, Canadian Engineers. Col. H. L. Trotter is a son of Col. W. C. Trotter, who for many years has been president of the Standard Clay Products, Ltd., of St. John's, P.Q., and New Glasgow, N.S. Col. H. L. Trotter graduated in 1903 from the Royal Military College, Kingston, with high honors, and then joined the firm of Ross & Holgate, consulting engineers, Montreal. When Mr. Ross and Mr. Holgate dissolved partnership, Col. Trotter joined Mr. Holgate as a junior partner. When war was declared, he enlisted immediately in the Canadian Engineers and was employed on fortifications below Quebec, and later installed new machinery in the Quebec Arsenal. He was also engaged in the construction of the Artillery Testing Depot in Quebec. From there he proceeded to Ottawa and, with the rank of major, took charge of an engineering company, but in England he was transferred to the 4th Division and placed in command of the 11th Field Company, which **later became the 11th Battalion.** This battalion particularly distinguished itself at the Somme in September, 1916, and at Canal du Nord two years later. The battalion was engaged in many other operations, however, including Vimy Ridge, Desire Trench, Arleux and Fresnoy, Lens, Hill 70, Passchendaele, Arras, Queant Drocourt Line, Denain, Valenciennes and the advance towards Mons. Col. Trotter was twice mentioned in despatches and was awarded the D.S.O.

Dr. Fred A. Adams of the Department of Health, Toronto, has been appointed medical health officer for the Essex border cities by the Essex Border Utilities Commission.

Lieut. Raymond Stevenson, of Fredericton, N.B., who recently returned home after four years' service overseas, has received an appointment on the Welland Canal staff.

Joseph Race, formerly city chemist and bacteriologist of Ottawa, Ont., returned home this week after six months' service in Siberia with the Canadian expeditionary force. Capt. Race will sail next week for a two or three months' visit to his former home near Manchester, England.

OBITUARY

Frank N. McReynolds, of the firm of Fussell & McReynolds, sewer contractors, Toronto, was accidentally drowned last Friday night at Honey Harbor, Ont., where he had gone for the purpose of repairing his summer cottage. A plank, across which Mr. McReynolds was walking, broke and dropped him into seven feet of water, where he was found on Sunday morning. It is thought that one end of the plank struck him on the head, rendering him unconscious. Mr. McReynolds was born 36 years ago at Cleveland, Ohio, but had resided in Toronto for the past eight years.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

BRIDGES, ROADS AND STREETS

Alnwick, Ont.—The contract for building the Hill Brook concrete arch culvert and roadway embankment in parish of Alnwick, Northumberland County, has been awarded to F. E. Berryman, Woodstock. Tender price about $6,800.

Annapolis Royal, N.S.—Tenders will be received until July 14th by board of highway commissioners, department of public works, Halifax, for concrete abutments and bridge sheets on ten existing piers.

Burlington, Ont.—The department of public works plans to construct new steel lift bridge across the channel at Burlington. Plans have not yet been prepared. It is thought probable that foundations may be put in this year and the superstructure completed early next spring.

Compton, Que.—Tenders for gravelling the Sherbrooke-Norton road in the limits of the village of Compton, from the south to the north limits of the macadam road of the township of Compton, will be received until July 5th, by J. A. Rivard, secretary-treasurer, Compton.

Crowland, Ont.—The Crowland township council has awarded contract for concrete pavement to be constructed from the M.C.R. to Ontario Rd. and then along the Ontario Rd. west to the canal, to Somerville and Dilworth, at $18,454. One other tender was received from Shaffey and Shaughnessy at $21,608.

Edmonton, Alta.—Repairs to Jasper Ave. estimated at $200,000 is proposed by the city council.

Edmonton, Alta.—It is proposed to repair road to Clover Bar and to construct several culverts.

Elora, Ont.—Tenders will be received until July 11th by S. Aitcheson, reeve of Pilkington township, Elora, for construction of 75-foot steel bridge, with concrete abutment, over Grand River.

Eriksdale, Man.—Contract for grading 24 miles of road has been awarded to Madden-Ledger Co., Eriksdale.

Fredericton, N.B.—New tenders have been called for the Harris bridge in Sunbury County and for the bridge at the mouth of Parks Brook, in Northumberland County.

Gladstone, Man.—Tenders will be received by P. St. C. McGregor, secretary-treasurer, Westbourne municipality, Gladstone, Man., until noon, July 10th, for the construction of two pile bridges over Whitemud River. Plans, specifications, tender forms and other information may be obtained from the secretary-treasurer's office, municipal hall, or from the highway commissioner, parliament buildings, Winnipeg.

Hading, Man.—M. Kelly, Winnipeg, has the contract for concrete culverts. Tender price, $9,555.25.

Kingston, Ont.—Arrangements are practically completed for a highway crossing the counties of Frontenac, Leeds, Lanark and Carleton.

Lachine, Que.—The town council will shortly present by-law for repairing portion of public highway.

Lunenburg, N.S.—Contract for pavement and sidewalk has been awarded by the town council to J. E. Lusby, Amherst, N.S.

Marmora, Ont.—The county council contemplates the expenditure of $30,000 on highways to the north in Tudor boundary to Maynooth. On the road from Belleville to Maynooth there has already been spent $10,175. Twelve bridges, at a cost of $21,000, are to be constructed.

Marquis, Sask.—Jedeberg and Gusa, Swift Current, have been given the contract for road work. Tender price, approximately $10,000.

Montreal, Que.—The Automobile Club of Canada has recently been taking up the matter of constructing a good road through to St. Anne de Bellevue, about 24 miles from the centre of the city. This road follows along the lake-shore.

Montreal, Que.—The city council is planning to construct 21,420 square yards of pavements on Cote des Neiges Rd. The total cost of paving with granite blocks will be $153,987. Grading will cost $7,568, concrete foundation $32,130, granite blocks $98,532, curbstones $1,061, gulleys and manholes $698. Inspection and engineering is estimated at about $13,998.

Montreal, Que.—The municipality of St. Victoire plans considerable macadamizing work this year.

Montreal, Que.—Paving of Redpath St., at a cost of $21,-700 is contemplated.

Newmarket, Ont.—Tenders will soon be called for bridge on Prospect Ave.

North Bay, Ont.—Tenders will be received until noon, July 18th, by H. J. McAuslan, for curbs and gutters, sidewalks and pavements. Official advertisement in this issue.

Oakville, Ont.—Tenders will be received until July 7th, by the town clerk for material and construction of tarvia or asphalt-macadam pavements on six streets; also a concrete pavement and curb on Dunn St. N. Engineers, Jas. A. Bell and Son, St. Thomas, Ont.

Ottawa, Ont.—Tenders will be received until noon July 18th, by Lynwode Pereira, secretary, department of the interior, Ottawa, for construction of Castle-Laggan highway, second section from station 355+00 to station 960+00, Rocky Mountains Park, Alberta. Contractors may tender for the complete work, or separately, for two timber bridges, one over Corral Creek at station 785+00, and one over Pipestone Creek at station 732+00. Also for Mount Revelstoke highway, from station 643+00 to station 747+00, Mount Revelstoke Park, Field, B.C. Plans and copies of contract may be examined and specifications may be had from the commissioner of Dominion parks, Ottawa, Ont., the superintendents of the Dominion parks at Banff, Alta., Jasper, Alta., or Field, B.C., the Dominion lands offices at Moose Jaw, Edmonton, Calgary, Revelstoke, Kamloops and New Westminster, and the office of the inspector of Dominion lands agencies, Winnipeg, Man.

Ottawa, Ont.—The proposed new Cummings bridge will cost about $200,000.

Ottawa, Ont.—The county council has sanctioned the taking over of the Metcalfe Rd., Montreal Rd., Ottawa-Pembroke Rd. and the Ottawa-Kingston Rd. No estimate as to the proposed cost has been made.

Ottawa, Ont.—Work on the 84 miles of road, from Hull to Maniwaki Rd., will be started this summer.

Overbrook, Ont.—Tenders will be received until noon, July 7th, by Patterson and Byrne, 71½ Sparks St., Ottawa, for the construction of approximately 7,425 lineal feet of granolithic sidewalk, four feet in width, on Prince Albert and Queen Mary Sts., from the Russell Rd. to Victor St.

Owen Sound, Ont.—Tenders will be received until July 18th, for construction of asphalt concrete pavements. Official advertisement in this issue.

Pembroke, Ont.—The Renfrew county council at its recent session gave assent to a by-law for the raising of $150,-000 for the county good roads system. The money will be secured by the issue of debentures over a period of twenty years. With the provincial grants which will go with the expenditure of this money, the total will aggregate about $225,000.

Portage la Prairie, Man.—Thos. Bell, 600 Sherburn St., Winnipeg, has been given the contract for superstructures of three Howe truss bridges. Tender prices: Poplar Point, $7,800; High Bluff, $7,800; Edwin, $8,000.

Port Hope, Ont.—In addition to widening, grading and draining the Kingston Rd., between Port Hope and Grafton, the department of highways will erect steel and concrete bridges. Tenders have been awarded for 24-foot steel and concrete bridges over the Gage's Creek and at Pontiac stock farm on Front Rd. E., and tenders have been called for a similar bridge at Abbot's Creek, just outside the town of Cobourg.

Ridgeway, Ont.—The construction of a half mile of concrete roadway is proposed. George Ross, engineer, has estimated the cost at $3.11 per yard. Of the total work the county would contribute $14,600, the township $1,550, and the frontage $5,854. A. Nelson, chairman of the good roads committee, has asked the council to call for tenders on tar macadam as well as concrete.

Rockwood, Wellington County, Ont.—Tenders will be received by A. Wood, reeve of Eramosa township, Rockwood, until July 10th, for 45-foot concrete arch truss bridge at Shiloh. Engineers, Bowman and Connor, 61 Queen St. W., Toronto.

Sandwich, Ont.—By-law has been passed by the town council for paving Centre Rd.

Sarnia, Ont.—Contract for pavements has been awarded to the Warren Bituminous Paving Co., Sarnia.

Smithville, Ont.—Work is going forward on an eleven-mile tar macadam road, which is being built from this point to Beamsville, to connect with the Hamilton-Niagara provincial highway. Four miles are being laid on the Niagara-Homer stone road to Virgil, and one mile is in the process of completion near the town of Niagara-on-the-Lake. From the provincial highway at St. Davids, a road will be constructed to the county boundary. As soon as the road from the experimental station, at Vineland, to the provincial highway, is approved by the department, a distance of two-and-a-half miles, work will be begun on that portion. The road from the highway to Grimsby Park, of tar macadam, has just been completed.

St. Catharines, Ont.—The county of Lincoln intends expending $311,000 for construction and maintenance of its county roads this year. For this purpose two stone-crushing quarries are being operated, one at Jordon and the other at Smithville, each capable of turning out about one hundred yards of crushed stone per day. Both plants are equipped with steam drills, derrick and hoist, and will be in operation all summer.

Ste. Marthe, Que.—George Sequin has been awarded the contract for iron bridge over the Laraquette River.

Sydney, N.S.—City engineer McKinnon has reported the estimated expenditure on streets to be $14,800.

Three Rivers, Que.—Tenders will be received until noon, July 15th, by R. C. Desrochers, secretary, department of public works, Ottawa, for the construction of concrete sidewalks, grading and seeding, public building, Three Rivers, P.Q. Plans and specification can be seen and forms of tender obtained at the offices of the chief architect, department of public works, Ottawa; the overseer of Dominion buildings, central post-office, Montreal, and the district engineer, Three Rivers, Que.

Timiskaming, Que.—The Hamilton Bridge Co. have been awarded contract for bridge over Quinze River.

Toronto, Ont.—Contracts for pavements have been awarded by city council as follows: Asphalt pavements to the city at an aggregate price of $16,692; bitulithic pavements to the Warren Bituminous Co., at $4,506.95, for Orchard Park Rd. and $13,447.70 for Prescott Ave.; brick block pavement, to the Godson Contracting Co., for $4,149; track allowance on Front St., to the city, at $13,561.

Toronto, Ont.—Contracts for concrete sidewalks have been awarded by the township of York as follows: The Grant Contracting Co., Dennis, Priscilla and Trijama Avenues, and John Walker, Westwood and Hillbrow Avenues. Contracts for other four streets were not let. New tenders are being called for this work.

Toronto, Ont.—Gerrard St. E. is to be graded at an estimated cost of $53,650. The board of control has approved of the recommendation of the commissioner of works that the work should be done by day labor.

Trenton, Ont.—J. P. Gordon, engineer, is preparing plans and specifications for construction of sidewalks. Estimated cost, $30,000.

Vankleek Hill, Ont.—Contract for bituminous macadam road, and for concrete gutter and culvert has been awarded to Sutherland and Grant, 339 Chapel St., Ottawa. Approximate tender price, $28,000.

Victoriaville, Que.—Construction of pavements is contemplated at a cost of about $20,000.

Victoria, B.C.—The tender of Luney Bros. to supply about 4,000 cubic yards of filling for the Rock Bay bridge site has been accepted by the city council.

Wawanesa, Man.—Tenders will be received by Thos. Stevenson, secretary-treasurer of Oakland municipality, Wawanesa, Man., until 6 p.m., July 11th, for the construction of reinforced concrete culverts and bridge in the municipality of Oakland. Plans, specifications, tender forms and other information may be obtained at the office of the highway commissioner, parliament buildings, Winnipeg, or the office of the district engineer, Virden, or from the secretary-treasurer of the municipality. A marked cheque to the amount of five per cent. of the tender price must accompany each tender. The lowest or any tender not necessarily accepted.

Windsor, Ont.—An international memorial subway under the Detroit River, connecting Windsor and Detroit, is a possibility of the future. The department of works, Ottawa, is sending engineers to look over the proposition.

Yamaska, Que.—Tenders will soon be called by the department of public works, Quebec, for gravelling and repairing 75 miles of road between Yamaska and Sorel. M. Henry, engineer, department of roads, Quebec.

York Township, Ont.—The township council has decided to pave Glenholme Ave. at a cost of $19,200, Lander Ave. at $6,980, Northcliffe Boulevard at $8,058.60, Oakwood Ave. at $21,900.

WATER, SEWAGE AND REFUSE

Barrie, Ont.—Debentures will be issued to the amount of $25,000 by the municipal council of the township of Innisfal for construction of tile, stone or timber drains. R. M. McConkey, clerk.

Blenheim, Ont.—The township council contemplates constructing a drain.

Brandon, Man.—Extension of the water and sewer mains to Richmond Ave. on Eighteenth St., will be undertaken by the city council. A sufficient quantity of cast-iron water pipe and filling will be purchased from the Gartshore, Thomson Co., at $84.10 a ton. This pipe will come in carload lots, twenty tons of the six-inch pipe to a carload. A sufficient quantity of sewer pipe will also be purchased from the Alberta Clay Products Co., as per their tender of June 14th. The ten-inch pipe will cost 38½ cents, the single junction costing $1.74 each, while the twelve-inch will cost 49½ cents, with the single junction $2.23½.

Chatham, Ont.—The water board will engage an engineer to report on best methods to adopt in erection of a modern water works plant.

Dundas, Ont.—An analysis of the bids received by the town council shows that sewers will cost approximately $240,000. Taking the lowest tenders, the following will be the approximate cost of the work: Laying sewers, $110,000; disposal works, pump and outfall sewer, $50,000; sewer pipe, $35,000; sewage pumping machinery, $2,700; sprinkler equipment, cast-iron pipes, valves, penstocks, etc., $9,500. Total, $207,200. In addition to this there will be a cost for land, engineering and inspection of around $15,000, and for 300 house connections, estimated at $17,000, bringing the

total estimated cost up to $239,200. Engineer Murdock estimated the cost to be $250,000. When the plans were made Murray and Lowes estimated the cost of the sewers and the storm sewers at $175,000. The work tendered on includes the construction of the whole sewerage system as laid out by Murray and Lowes. It provides for sewers on South St., Ancaster Rd., Dundas St., Baldwin St., North St., York St., from Main to Hunter's farm, through Hunter's farm to disposal works, Hatt St., Market St., McNab St., Peel St., James St., King St., from York to Head, Cross St., from King to the Park, Park St., from York to Head St., Melville St., from Cross to Brock, Witherspoon St., from Market to end, Foundry St., Miller's Lane, Princess St., Albert St., Elgin St., Sydenham St., from Park to Short St., Victoria St., Alma St., from Cross to Sydenham. The bulk bids submitted were: F. F. Fry, $99,071; A. R. C. Smith, $102,172.75; Curran and Clement ,$152,031.65; Canadian Engineering and Construction Co., $216,583.65; Connolly-Agnew Construction Co., $228,222; B. O. Johnson, $166,667.75; Jas. D. Armstrong, $189,965. Contract has not yet been awarded.

Edmonton, Ont.—The following tenders were received by the city council for construction of clear water basin for the city filter plant: J. Dunlap, $20,123.89; Swanson and Kaline, $18,129.05; Hulbert, Wilson and Southworth, $19,348.10; Emil Skarin, $18,670. The contract has been awarded to Swanson and Kaline.

Edmonton, Alta.—Plumbing contract for agricultural schools at Raymond, Youngstown and Gleichen has been given to Ross Bros., Edmonton. Aggregate tender price, $33,000.

Hamilton, Ont.—The department of public works, Toronto, will soon call for tenders for reservoir.

Harriston, Ont.—Tenders will be received until July 14th, by W. D. McLellan, township clerk, for open ditch drain in the township of Minto. Total length of drain is 7,932 feet and amount of excavation is about 5,500 cubic yards.

Montreal, Que.—Contracts for sewers have been awarded to lowest bidders by the city council as follows: Alexandra Ave., to the De Keyser Wauters Co., at $17,931; Girouard Ave., to the De Keyser Wauters Co., at $4,809; Van Horne Ave., to the De Keyser Wauters Co., at $3,489; and Oxford Ave., to the Federal Engineering and Contracting Co., Ltd., at $10,785.

Montreal, Que.—The harbor commissioners have awarded the contract for erection of the piles for the new cold storage plant to the Douglas Milligan Co., Montreal, representatives of the McArthur Concrete Pile and Foundation Co., of New York. The work of placing test piles is almost finished, under the direction of F. W. Cowie, harbor engineer, and the permanent work will be proceeded with at once. Within the next few weeks contracts for the superstructure will be considered.

Newmarket, Ont.—Plans and specifications have been prepared and tenders will soon be called for construction of sewers on several streets.

Ottawa, Ont.—The city council will soon be asked to provide $100,000 to replace the intake pipe which now supplies water to the Queen St. pumping station.

Owen Sound, Ont.—One tender for construction of filter bed was received by the town council and that was considered too high, $3,000. Plans were prepared by engineer R. McDowall and work will be done under his direction.

Sandwich, Ont.—By-laws have been passed by the town council for constructing a sewer on Tonier St., also one on Brock St., and for water main on Wyandotte St.

Sarnia, Ont.—Tenders will be received by John A. Baird, city engineer, Sarnia, until noon, July 4th, for the construction of vitrified sewer on Mackenzie St. Plans, profiles, specifications and forms of tender may be seen at the office of the city engineer, City Hall.

Sarnia, Ont.—The city council has decided to construct a vitrified tile drain on Water St., at a cost of $1,220.45; also a vitrified tile sewer on Rose St., at a cost of $839.52. J. J. Stewart, city clerk.

Simcoe, Ont.—The public utilities commission is in the market for centrifugal pump for sewage disposal plant. Guy R. Marston, engineer.

St. John, N.B.—An engineer has advised that the new 36-inch pipe for the proposed extension of water main to Spruce Lake, would increase the supply of water from 4,000,000 gallons to 12,000,000 gallons a day. The cost of the proposed extension is $300,000. This would bring the total cost of the West Side water system to $700,000.

St. John, N.B.—Tenders will be received by J. B. Jones, commissioner W. and S. department, until July 17th for excavating and backfilling the trench for laying approximately 420 feet of 16-inch and 1,126 feet of 12-inch cast-iron pipe, according to the plans and specifications to be seen in the office of the city engineer.

Toronto, Ont.—Works commissioner R. C. Harris will present a report to the city council in the near future in which he will advocate the construction of a new filtration and pumping plant in the east end of the city (at Victoria Park), and the construction of new mains. Mr. Harris desires the plant to be designed for a capacity of 60-million imperial gallons a day. The construction of this plant will also mean the construction of a new intake at Victoria Park. It will relieve the filtration plants at the Island and will provide for the expected growth of population during the next few years.

Toronto, Ont.—Officials of the works department, city of Toronto, will visit Milwaukee at an early date, to investigate the activated sludge process. If they are satisfied with the progress that has been made by Milwaukee, the Toronto city council will allow the expenditure of $50,000 for an experimental unit which, if successful, will result in the construction of a large plant to handle all of Toronto's sewage.

Toronto, Ont.—Contract has been awarded by the city of Toronto for supply of filter alum for the current year to the Nichols Chemical Co., Toronto.

Verdun, Que.—$246,775 will be expended by the town council on improvements to water plant.

Verdun, Que.—Chas. Brandeis, engineer, has prepared plans and specifications for filtration system, water distribution, electric light and power system and an incineration system. The engineer has recommended the following: (a) Two 5,000,000-gallon electric pumps, a 4,000,000-gallon filtration plant and about 4,000 feet of 24-inch water main in the street, at an approximate cost of $246,775; (b) a 1,000 k.w. steam turbine generator and boilers, at an approximate cost of $150,000; and (c) an incineration plant for the destruction of garbage, which plant might also be used for the production of power, with the necessary dyke, etc., at an approximate cost of $106,150. Each of these amounts will be provided for by a separate loan by-law. T. F. Dwyer is the contractor for dyke.

Woodslie, Ont.—Tenders will be received by A. Mousseau, clerk of Maidstone, Woodslee, Ont., until noon, July 7th, for the dredging and other improvements of the Pipe Creek drain. Plans and specifications can be seen at the office of Jas. S. Laird, Essex, or at the office of the clerk at Woodslee.

Yellow Grass, Sask.—Contract for supply of water mains, valve, casing and cup, with plugs, ties and hydrant, has been awarded to H. C. Dupont, Yellow Grass, Sask.

BRIDGE TENDER

Tenders will be received up to noon, Friday, July 11th, for the erection of a thirty-foot concrete bridge on Prospect Street, Newmarket, Ontario. Plans and specifications may be seen at the office of the engineers, James, Loudon & Hertzberg, 36 Toronto Street.

Tenders must be marked, sealed and addressed to J. P. Anderson, Clerk, Newmarket, Ontario.

C. W. LUNDY, Chairman, Committee. P. J. ANDERSON, Clerk.

No Damage at these Curves!

Entrance to Queen Victoria Park, Niagara Falls, Ont. Roadway surface treated in June 1918 with "Tarvia-B."

When swift and heavy automobiles sweep around the bend of an ordinary macadam road the tires slip sidewise—not enough to skid, to be sure, but enough to rub and rasp the brittle macadam until the stones loosen and the surface ravels.

No road is better than its curves.

The curves are always the first spots in a road that need repair.

With plain macadam construction the curves are a *constant source of trouble and expense.*

Not so with Tarvia-macadam: Note the excellent condition of the curves in the Tarvia roads pictured here.

Curves have no terrors for Tarvia, because when it is used as a binder it forms a tough matrix for the crushed stone. Not only has Tarvia greater bonding power than natural binder, but it has the further element of *plasticity*, so that it yields instead of crumbling.

Tarvia solves motor-traffic problems.

The use of Tarvia reenforces the road-surface and makes it strong enough to resist motor-driven traffic, which to-day is the biggest problem of the roadmaker.

Likewise with the erosion problem: Water on steep grades washes out plain macadam but does not harm the Tarvia-macadam because it is absolutely waterproof.

And remember, Tarvia roads are also *frost-proof, mudless, and dustless,* and cost less than any other type of good-road construction.

Illustrated booklet describing the various Tarvia treatments free on request.

The Barrett Company LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER
ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

Summit Crescent, West Crescent Height, Westmount, a suburb of Montreal. Treated with Tarvia.

Special Service Department

This company has a corps of trained engineers and chemists who have given years of study to modern road problems. The advice of these men may be had for the asking by any one interested. If you will write to the nearest office regarding road problems and conditions in your vicinity, the matter will have prompt attention.

Main Driveway, Queen Victoria Park, Niagara Falls, Ont., north of the Administration Building.

York Township, Ont.—The township council has authorized the issue of $18,000 in debentures to cover cost of installing sanitary plumbing and drainage in King George and George Syme schools, S.S. No. 29. By-laws have been passed to lay approximately 30,000 feet of water mains through the north-eastern section of the township.

York Township, Ont.—The York township council proposes to install private sewerage and water works systems on the east side of the township. On the west side systems are now under construction. The district it is now proposed to improve lies south from St. Clair Ave. to the city limits and east from the Don to Scarborough townline. It is proposed to drain the district towards the Don, where a sewerage disposal plant will be erected. The water supply will be obtained from Lake Ontario.

LIGHT, HEAT AND POWER

Alexandria, Ont.—It is proposed to serve the village of Lancaster and the town of Alexandria with hydro-power from the St. Lawrence system. Investigations are being made to determine the most feasible way of meeting the needs of the district surrounding the municipalities.

Edmonton, Alta.—H. H. Depew, Edmonton, has the contract for electrical work for three agricultural colleges at Raymond, Youngstown and Gleichen. Aggregate tender price, $3,419.

Hamilton, Ont.—The Dominion Foundry Co. will install electric ovens at their plant.

Kapuskasing, Ont.—The Spruce Falls Pulp & Paper Co. expect to go ahead with the construction of a pulp mill near Spruce Falls, on the Kapuskasing River. In connection with this enterprise there will be a hydro-electric power development, with an initial output of 9,000 h.p., and an eight or nine-mile transmission line to the mill. American interests are said to be behind the company, and it is stated that the company has $6,000,000 capital underwritten by an American firm. E. Stewart, managing-director of the Canada Timber and Lands, Ltd., Standard Reliance Building, King St., Toronto, is promoting the company. Engineers are now at work on the property.

Kippawa, Que.—Contract has been let by the Kippawa Co., Ltd., for piping, to the John W. Danforth Co., of Buffalo, N.Y.

Kippawa, P.Q.—Contract was let recently by the Kippawa Co., Ltd., for valves to H. G. Hunter, Montreal, representing the Rensselaer Valve Co., of Troy, N.Y.

Mansfield, Ont.—The Galetta Electric Power and Milling Co. has decided to construct line from their plant to Mansfield.

Merrickville, Ont.—The new unit of the Rideau Power Co., of Merrickville, was put in operation on May 3rd, and the load on the system has been increased so that two additional blocks of power are required immediately.

Montreal, Que.—The Canada Electric Co., 250 Beaver Hall Hill, has been awarded the electrical contract for the extension of the academy of Notre Dame de Bonsecours on Fairmount Ave. Also for the Rushbrooke Protestant school, Verdun.

Montreal, Que.—L. E. Moulton & Co., 142 Inspector St., has been awarded the plumbing and heating contract for the new Davidson plant, Delisle St.

Nicomen Island, B.C.—No contract has been awarded by department of public works for dam, embankment and three groynes at Nicomen Island, Fraser River, B.C. It has been decided to call for new tenders some time next fall.

Parry Sound, Ont.—Contract has been awarded to W. M. Fletcher & Co., 151 Bloor St. W., Toronto, for the dam, power house and earth fill required in connection with the municipal hydro-electric power scheme that is being undertaken here. Contract price, $64,700. Contract for the electrical equipment, including generators, has been awarded to the Canadian Westinghouse Co., Ltd., Hamilton. Contract price, $21,060. C. H. and P. H. Mitchell, consulting engineers, Toronto.

Perth, Ont.—The hydro line, from Perth to High Falls, has been completed. A temporary transformer station has been installed at High Falls to supply power for construction purposes.

Portage la Prairie, Man.—This city will soon be supplied with hydro-electric power. Mayor Metcalfe.

Wellington, P.E.I.—A modern 4,000-volt distribution system is being constructed by the local commission to replace the 250-volt d.c. system, formerly owned by the W. P. Niles Seed Co.

RAILWAYS

New Waterford, N.S.—A proposal to extend the railway tracks from New Glasgow to this town is under consideration. A. Stuart Pratt, president, C. B. Electric Co.

Toronto, Ont.—It has been decided to straighten the north street railway curve on Broadview Ave. Estimated cost, $8,231.

FACTORIES AND LARGE BUILDINGS

Brandon, Man.—The city council proposes to erect an aerodrome in this city.

Chatham, Ont.—The Bell Telephone Co., Montreal, contemplates erection of telephone building.

Clarke City, Que.—The Gulf Pulp and Paper Co., Ltd., will soon erect addition to plant.

Donnacona, Que.—Time for receiving tenders for store and office building by Delisle and Floyd has been extended to July 2nd.

Edmonton, Alta.—Contract for three agricultural schools at Raymond, Youngstown and Gleichen has been awarded to Smith Bros. and Wilson, Lethbridge, for the aggregate sum of $144,000.

Falls View, Ont.—Tenders are being called by C. M. Borter for addition to public school, costing about $20,000.

Fredericton, N.B.—R. Chestnut & Sons contemplate erection of brick or concrete three-story building at an expenditure of about $25,000.

Fredericton, N.B.—The directors of the agricultural society have decided to erect a new exhibition building.

Fredericton, N.B.—The R. Chestnut and Sons, Co., Ltd., proposes to reconstruct three-story brick building into warehouse.

Fredericton, N.B.—Construction of a new union station near Regent St. is contemplated.

Galt, Ont.—Schultz Bros., Brantford, have been awarded the contract for Hugh McCulloch Memorial Nurses' Home.

Galt, Ont.—Tenders will be received by Joseph McCartney, secretary, housing commission, until July 15th, for all trades required in the erection of fifty houses, half to be of four rooms and half of six rooms, and alternately, for one hundred houses, half to be of four rooms and half of six rooms. Plans and specifications may be obtained from Evans and Hall, associated architects, 30 Water St. N., Galt, Ont.

Hamilton, Ont.—Contract for erecting bathing pavilion at Wabasso Park has been awarded to the Canadian Engineering and Contracting Co.. Tender price, $20,700. The T. J. Drake Co. submitted two tenders, one for $15,588, and another for $19,680. Other firms that tendered were: W. H. Yates, jun., $21,037; Frid Construction Co., $25,000; Wm. R. Tope, $24,290; Mitchell and Riddell, $21,300; and Stuart Bros., $26,820.

Hamilton, Ont.—New masonic temple to be erected here will cost $350,000.

Hamilton, Ont.—The Frid Construction Co. have been awarded the contract for erecting a boiler house at Gage Park. Estimated cost, $8,600.

Kapuskasing, Ont.—New pulp mill and townsite are planned in connection with Spruce Falls Pulp & Paper Co. For further information, see item under "Kapuskasing" in Light, Heat and Power section of this issue.

Kingston, Ont.—It is proposed to erect new barracks at Barriefield.

Kitchener, Ont.—A new packing plant and abattoir will be erected on Guelph St., by Dumart Bros. Estimated cost, $75,000.

Leamington, Ont.—The Imperial Tobacco Co., 900 St. Antoine St., has awarded contract for plant to Archibald and Holmes, Toronto. Contract price, $125,000.

London, Ont.—Building permits since June 1st, number 95, the total value being $99,950.

Lotbiniere, Que.—The Lotbiniere Exposition Co. contemplates the erection of fair buildings. Estimated cost, $100,000.

Maisonneuve, Que.—The Anglin Norcross Co., 65 Victoria St., Montreal, has been awarded the contract for $20,000 warehouse for the United Shoe Machinery Co.

Montreal, Que.—The Laval Industrial Co. contemplates the erection of stamping works to cost $25,000.

Montreal, Que.—The Dominion Oilcloth Co., 1192 St. Catherine St. E., has awarded the contract for a $30,000 warehouse to J. Meloche, 1911 Masson St.

Montreal, Que.—Contract for construction of public baths has been awarded to Duraneau and Co., 113 Hamilton St., Emard Ward.

Montreal, Que.—Fire has destroyed one of the buildings in the C.P.R. Hochelaga yards. Loss estimated at $25,000.

Montreal, Que.—C. P. Fabien, 31 St. Cunegonde St., contemplates extension to refrigerator plant, at an approximate cost of $30,000.

New Toronto, Ont.—Contracts for the construction of 54 houses have been awarded by the local housing commission to Herbert Baxter. J. Doughty, Mimico, will install heating, plumbing and wiring.

Oshawa, Ont.—St. George's Church congregation contemplates erection of a $95,000 church.

Petrolia, Ont.—The Lambton County Corn Growers' Association contemplates the erection of a one-story steel fair building. Director, J. C. McMillan.

Picton, Ont.—The True Blue Orphanage will shortly enlarge their building. Estimated cost, $200,000.

Regina, Sask.—Alex. Pantages contemplates erection of new theatre with seating capacity of about 1,400.

Regina, Sask.—A new warehouse will be erected next year by the Saskatchewan General Trust Co.

Regina, Sask.—Tenders will soon be called for provincial police headquarters. Estimated cost, about $175,000.

Regina, Sask.—The Saskatchewan General Trust will erect a large store on the corner of Lorne St. and 11th Ave. Estimated cost, $30,000.

Sandwich, Ont.—A by-law will be voted on shortly to authorize expenditure of $50,000 for new school. Roger S. Agnelly, chairman.

Shawinigan Falls, Que.—A branch building costing $20,000 will be erected by the Royal Bank of Canada, Montreal.

St. John, N.B.—Tenders will be received until noon, July 4th, by R. C. Desrochers, secretary, department of public works, Ottawa, for alterations and additions to fittings in the post office. Plans and specification can be seen and forms of tender obtained at the offices of the chief architect, department of public works, Ottawa, and the superintendent of Dominion buildings, St. John, N.B.

St. Omer, Que.—The parish of St. Omer will remodel church at a cost of $22,000.

St. Thomas, Ont.—Contract for pavilion at Pinafore Park has been awarded to the Green Lumber Co. Tender price, $8,396. Other tenders were: Alfred Morris, $9,875; Sanders and Bell, $7,525, for carpenter work only; Orlando Beal, $1,639, for cement work.

Sydney, N.S.—Contract for new Roman Catholic church has been given to Bate, McMahon Co., Sydney. Tender price, $100,000.

Three Rivers, Que.—Thomas Trow, Port Henry, N.Y., contemplates erection of theatre to cost about $50,000.

Toronto, Ont.—Plans are being prepared for erection of modern reception hospital. Estimated cost, $50,000.

Toronto, Ont.—Tenders will be received by Wm. Steele and Sons Co., Ltd., until July 14th, for erection of furniture store building for the Adams Furniture Co., Ltd. Plans and specifications may be seen at the office of Wm. Steele and Sons Co., Ltd., 512 Ryrie Building, Toronto.

Walkerville, Ont.—The American Auto Trimming Co. will erect a five-story addition to their plant.

Walkerville, Ont.—The Peabody Manufacturing Co., Ltd., will erect a $500,000 textile plant here.

Windsor, Ont.—S. E. Dinsmore, Windsor, has been given the contract for addition to school. Tender price, $47,000.

MISCELLANEOUS

Brantford, Ont.—The war memorial committee has decided to erect an obelisk as a memorial to fallen heroes.

Connaught Station, Ont.—Tenders will be received until noon, July 15th, by R. C. Desrochers, secretary, department of public works, Ottawa, for the construction of a timber pilework wharf at Connaught Station, district of Timiskaming, Ont. Plans and forms of contract can be seen and specifications and forms of tender obtained at the department of public works, at the post office, Haileybury, Ont., and at the post office, Connaught Station, Ont.

Devil's Island, N.S.—The department of public works has awarded contract for repairs to breakwater to M. A. Condon and M. C. Denton, Digby, N.S.

Luseland, Sask.—Hisey and O'Bready, Kindersley, Sask., have been awarded contract for extensions to telephone system.

Magog, Que.—Thos. P. Charleston, Ottawa, has been awarded contract by the department of public works for repairs to wharf.

Ottawa, Ont.—George Roberts, 77 Lagauchetiere St. W., Montreal, has been awarded contract for screens, panelling and woodwork at the new parliament buildings, Ottawa.

Ottawa, Ont.—Tenders will be received until July 9th for rubber flooring required in construction of parliament buildings. Official advertisement in this issue.

Port Arthur, Ont.—The department of public works, Ottawa, has awarded contract for repairs to temporary pile protection breakwater to the Barnett-McQueen Co., Ltd., Port Arthur, Ont.

Toronto, Ont.—Tenders will be received until July 15th, by T. L. Church, chairman, board of control, for the complete supply and erection of metal fire escapes on the isolation hospital buildings of the city of Toronto. Specification and blue print may be seen and tender form obtained, together with all information pertaining thereto, at the office of the property department, City Hall, Toronto.

Victoria, B.C.—Tenders will be received by the minister of lands until noon, July 10th, for the construction and completion of approximately eight miles of main irrigation canal from the point of diversion on Okanagan River. Plans, specifications, contract and forms of tender may be seen at government agent's offices at Fairview and Vancouver, and at the water rights branch, Victoria. E. A. Cleveland, consulting engineer to the department of lands.

Winnipeg, Man.—Tenders will be received until July 10th, by Geo. A. Grierson, minister of public works, for assembly and erecting materials in connection with construction of transmission line between this city and Portage la Prairie. Official advertisement in this issue.

A Weekly Paper for Civil Engineers and Contractors

Making Concrete Blocks for Toronto Breakwater

New Plant Located on Toronto Harbor Commissioners' Reclaimed Dockage at Foot of Spadina Ave.—Pouring Concrete Blocks Weighing 10 and 18 Tons Respectively—Special Design of Collapsible Wooden Forms—Economical Handling in Limited Space

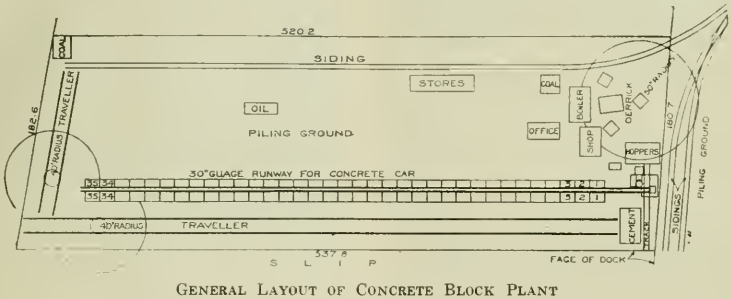
By FREDERICK PHILLIPS
Assistant Engineer, Roger Miller & Sons, Ltd., Toronto

THE plant described herewith was erected for the purpose of making the large concrete blocks used in connection with the cribs laid between the Western gap and the Humber River, Toronto, to form a breakwater approximately four miles long and which in turn forms a part of the complete harbor improvement scheme.

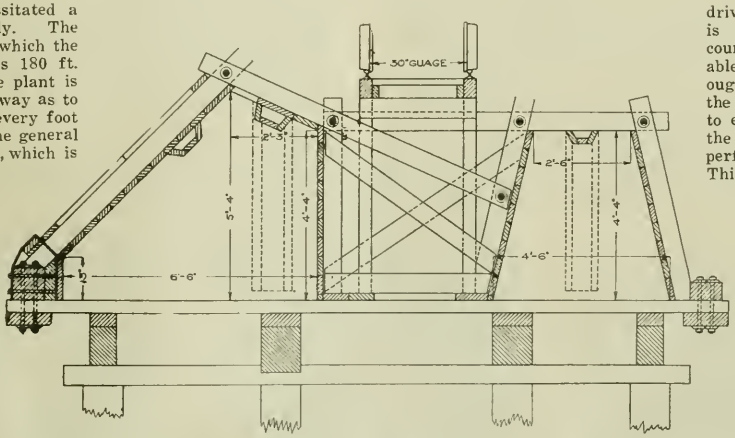
The plant is located at the south end of Spadina Ave., with a slip 200 ft. wide on the east side and the open bay to the south.

The effort to provide a layout that would be economical and at the same time enable the entire area of the plant to be used, necessitated a very careful study. The size of the lot on which the plant is located is 180 ft. by 538 ft. and the plant is utilized in such a way as to make practically every foot of it valuable. The general layout of the plant, which is shown by the accompanying illustration, will demonstrate this.

The position of the mixing plant is such that the material can be handled very conveniently. The stiff leg derrick is set at a height above the general car level to allow the operator to see the car that is being unloaded, and is set in such a position that it will reach across on either side and dump into the material bin or into the triangular storage space between the two tracks, providing ample storage within a very small radius. The cement storage was placed on the opposite side of the mixing plant, so as to be convenient for unloading cement either from boats or cars.



GENERAL LAYOUT OF CONCRETE BLOCK PLANT



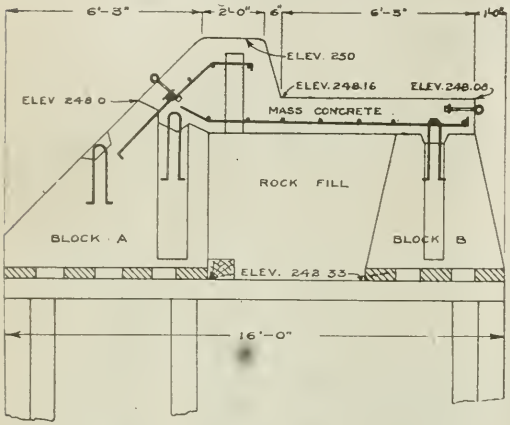
CROSS-SECTION OF COLLAPSIBLE FORMS USED IN CONSTRUCTING CONCRETE BLOCKS

The cement is conveyed from this shed to the mixer on small cars at such a level that it will dump into bucket or hoist conveniently. The material is then hoisted and dumped into a batch hopper on the side of the tower, which in turn desposits into a Smith steam-operated 1-yard concrete mixer and is discharged directly from the mixer into the cars. These side-dump cars are of special design and run along a narrow gauge track between and above the forms, and are operated by an endless cable.

The forms are built on a platform 4 ins. thick and supported on beams and piles driven to rock. This is necessary on account of not being able to get a solid enough foundation on the made ground so as to ensure the floor of the forms being kept perfectly straight. This platform is 400 ft. long, 20 ft. wide and rests on 148 piles. Located above the centre of the platform and running the entire length is a light trestle framing which supports the car tracks and is sheeted on either side to form the backforms of the blocks, thus making a continuous wall. The forms are made of 1¾ in. spruce, 3 ins. by 6 ins. and 4 ins. by 6 ins. studding, and are all connected with bolts and angles with slotted holes so that the forms can be released about 1 in. away from the blocks without entirely removing them, after the concrete has set from 12 to 24 hours. This gives a free circulation of air without allow-

ing the hot sun to strike the concrete and materially assists in the drying and hardening. The parts of forms are all interchangeable and are set to permanent gauge forms located on floor and back wall, thus making it unnecessary to sort out forms when stripping or replacing. The forms are arranged in pairs similar to the position they will occupy when permanently set on the cribs. The large blocks which are placed on the lake side of the breakwater contain 8.9 cu. yds. of concrete and weigh 18.04 tons, while the smaller blocks which go on the shore side contain 5.25 cu. yds. and weigh 10.6 tons. No reinforcing is used in these blocks but keys and rods are provided for the anchors for the mass concrete which is formed on top of these and there are also U-bolts set in the blocks for lifting purposes.

Between the forms and the slip a 20-ton travelling derrick on a 12 ft. gauge track is located to handle forms, lift blocks and transfer to scows from whence they are



Cross-Section of Superstructure of Breakwater, Showing Mass Concrete over Concrete Blocks

towed to the location of the breakwater, where they are set by a derrick scow especially equipped for the job.

At the south end of the dock is a 10-ton travelling derrick for loading the one-man stone to be placed in the cribs.

The plant is well provided with the necessary smaller buildings, blacksmith shop, stores, office, carpenter shop, etc.

The plant is capable of pouring 200 cu. yds. per 8-hour day, which is equivalent to about 14 of each size of block. The entire plant and equipment, including the derricks, was built by Roger Miller & Sons, Ltd., and designed and supervised by A. E. Gibson of the same firm.

At a recent meeting of the branch of the Engineering Institute at St. John, N.B., the following resolution was passed: "Whereas, the people of Canada are confronted with the problem of carrying the very heavy national debt incurred by their participation in the great war for humanity, and whereas this burden can be borne only through the greatest thrift and industry on the part of the nation, through the conservation and development of our human and natural resources, so that we may be able to share in the world's markets against the strong competition that we shall have to meet, be it therefore resolved that the St. John Branch of the Engineering Institute of Canada do hereby declare their heartiest support of the establishment by the government of Canada of a National Research Institute, which shall carry on and direct research into such industrial, agricultural, commercial and medical problems as will best promote such conservation and development of Canada's resources, and that copies of this resolution be sent to the council of the Institute to be forwarded to the government."

ADVANCE IN CHLORINATION AND ITS EFFECT ON TYPHOID FEVER*

By John Kienle
Sanitary Engineer, Electro-Bleaching Gas Company, New York City

Chlorination of public water-supplies has been the most noteworthy single contribution to the art of water purification in recent years. The effect of this method of water treatment in reducing the typhoid mortality of the country at large is attested not only by the statistics but by the increasing demand of public health authorities for this method of protection.

Chlorination of water by the hypochlorite of lime method was first carried out successfully in the United States by George Johnson at the Union Stock Yards at Chicago in 1907, and almost immediately followed by the treatment of the Jersey City supply at Boonton. By the end of 1911, approximately 500 water plants had been equipped with hypochlorite installation. In 1912, the use of liquid chlorine was announced at the Minneapolis convention of this association. Although the increase in the use of hypochlorite was quite rapid following its appearance at Boonton, the rate of growth of the liquid-chlorine process was even more remarkable. From only one water plant (Niagara Falls), equipped at the end of 1912, the number at the end of 1918, had jumped to approximately 2,500.

In 1907, the United States Census Bureau tells us, the typhoid-fever death rate in the registration area, with a population of 41,758,000, was 30.3 per 100,000, and the estimated number of deaths within the year for the entire country was approximately 30,000. There were then no chlorinated water-supplies. In 1917, according to the United States Public Health Service, the rate had dropped to 12.3 per 100,000, with the estimated number of deaths stated at 13,000, and in this year there were at least 2,000 public water-supplies that were chlorinated. Thus 17,000 lives were saved from death by typhoid in one year. This is a saving of over $125,000,000 annually.

It has been aptly stated that the chlorination of public water-supplies is the cheapest municipal insurance that can be obtained, the average annual premium amounting to not more than 40c. per 1,000,000 gals. of water treated, or, for a municipality of 5,000 or less, an annual expense of $150 per annum ($36.50 operating, and $120.00 depreciation at the rate of 20%) or a cost of 3c. per capita, based on the same figure of 5,000 population.

Wanted, copies of the June 5th, 1919, issue of *The Canadian Engineer*. Any subscribers who have no further use for their copies are requested to forward same to the Circulation Department, *The Canadian Engineer*, Toronto.

The Federal Highways Bill has passed through the committee of the House of Commons. Under its provisions, each province will receive an initial grant of $80,000. The balance of the $20,000,000 will be awarded to the provinces on a basis of population.

In discussing Mr. Breed's paper on concrete in road, culvert and bridge work, which was read at the good roads convention in Quebec, E. Drinkwater, consulting engineer, of Montreal, inquired regarding the use of box sections for culverts instead of pipe, asking whether Mr. Breed had not experienced trouble with water getting into the pipe and freezing. He also asked whether the 1:3:5 mix had been found suitable for box culverts. Mr. Breed said that he had experienced some difficulty in connection with concrete pipe culverts along the lines indicated by Mr. Drinkwater. He thought that a better mixture for the box culverts is 1:2½:5. The United States government specifies 1:2:4, but the New York State Commission prefers 1:2½:5 as giving the best results, and the only two failures that they have experienced in three years in using this mix were from dirty aggregate.

AIR-LIFT PUMPING

By John Oliphant
Manager, Air-Lift Pumping Dept., Sullivan Machinery Co., Chicago

WHILE I am not going to enter at this time into the principles of air-lift pumping, I would like to call your attention to the advisability of a perfect emulsion of air and water at the footpiece in order to secure the best economy, and also to lay stress upon the care with which should be calculated the diameters of the water and air pipes for different lifts and different submergences.

While it is a fact that there are several types of mechanical deep-well pumps that, up to certain depths, will give

Well-Head and Separating Tank at Galesburg, Ill.—Air Receiver at the Right

theoretically a higher efficiency than air-lift, yet this difference in efficiency is theoretical rather than practical. It has been demonstrated time and again that air-lift, even with its lower theoretical overall power efficiency, but with immunity from derangement, has been placed ahead of the deep-well pumps under many conditions of operation.

The village of Maywood, a suburb of Chicago, has a compressor handling a single well, pumping at the rate of 700 gals. per min., with a lift of over 300 ft. This compressor has been operating for

Belt-Connected Air Compressor at Galesburg, Ill.

Air-Lift Booster at Maywood Water Works

Discharge into Weir Box over Concrete Storage Basin at Galesburg, Ill.

four years, 24 hours per day, with a stoppage of only a few minutes during the 24 hours for necessary examination and adjustments. This plant has been operated at the above capacity continuously at absolutely no cost for repairs and no shut-downs, except those above indicated. I believe this would compare favorably with the operation of a mechanical deep-well pump even at its higher rated efficiency.

There are a great many occasions where the air-lift can be used as an auxiliary to a high-duty suction plant pumping from deep wells. Such a case came up over a year ago at Clinton, Ill., where they secure their water by suction from deep wells, and for ordinary purposes secure a sufficient amount by this method. But in case of peak loads in the summer, and in case of fire, it was found that the supply secured by suction was not sufficient to cover their requirements.

The supply is secured from some half-dozen wells, having a surface flow of limited volume. These are connected so as to flow into a surface reservoir, or may be direct-connected to mains by means of suction pumps. Experience showed that when suction was resorted to, the supply for

Flushing a Well at Clinton, Iowa

the summer hot weather load, or for an extended fire demand, was insufficient. Three of the wells were therefore connected with an air-lift system arranged to discharge into the reservoir, using the suction piping as a gravity flow line.

A suitable arrangement of valves is provided to permit this flow from the wells to the reservoir, while the service pumps draw their supply from the reservoir by suction. By this arrangement, the water supply was more than doubled from these three wells.

One of the 8-in. wells had a natural artesian flow of about 150 gals. per min. When under suction from the pumps, the pull-down was 20 ft., increasing the flow to 500 gals. per min. When this well was connected up for operation under the air-lift, its production was increased to 1,035 gals. per min., the pumping head being 50 ft. below the surface. The other two wells, connected up in the same manner, showed a proportionate increase.

These wells are handled by means of an air-lift pump suspended on a 2-in. air line in the 8-in. casing. The air for operating the wells is supplied by a straight-line simple steam and compound air compressor, size 14 by 16 by 10 by 16 ins., having a capacity of 558 cu. ft. of free air per min. The installation was effected in a simple and economical manner, piping the air from the receiver to and into the wells. On ordinary service, the pumps secure sufficient supply by direct suction. When an increase is demanded by the summer domestic requirements or by fire, it is merely necessary to start the compressor, throw a few valves, and the supply from the wells is more than doubled.

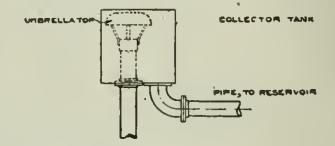
For general information I include below some figures secured from two installations made at Galesburg, Ill. The first of these has been in operation over a year, and the second about six months. These plants are located at different points in the town and centrifugal pumps used to take the water from the service reservoirs and force it directly into the mains. You will notice that the efficiency indicated in these reports is the electric in-put to the motor as compared to footpounds of work done, and includes all motor, transmission and compressor losses, and we believe will compare favorably with the highest type of mechanical pump under the severe lifts obtaining at these installations.

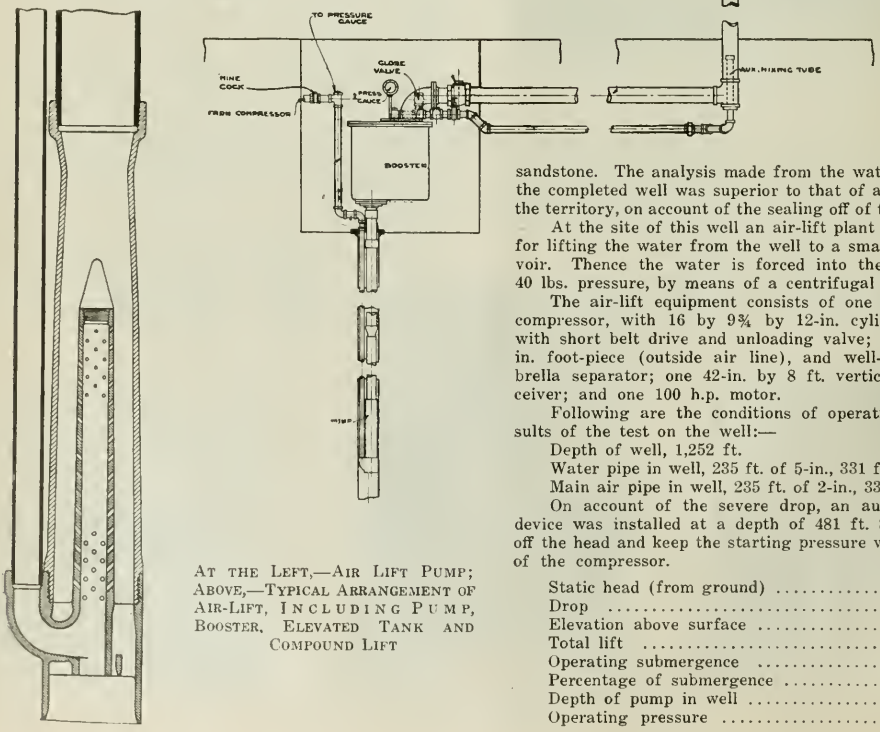
The city of Galesburg, Ill., has had considerable difficulty in securing sufficient water for the public supply. A number of wells in the neighborhood of the old pumping plant have been driven and equipped with various devices, but failed to give the amount of water needed. The old plant consists of three deep and six shallow wells, with a combined yield of about 250 gals. per min., and has been very expensive to operate and maintain, and it was therefore determined to sink a new well.

The construction of this well was as follows: 40 ft. of 24-in. heavy steel casing; 106 ft. of 20-in.; 130 ft. of 16-in.; and 350 ft. of 12-in. steel casing. The 12-in. is sealed in the rock. The hole was then drilled 12 ins. in diameter to a depth of 1,085 ft. from the surface, then reduced to 10 ins. and drilled down to 1,255 ft. through the St. Peter's sandstone formation.

The well was then shot with two 200-lb. charges of 100% gelatin, covering the entire sand rock strata, and carefully cleaned out.

Genuine wrought-iron 10-in. pipe was installed and sealed into the top of the 12-in. pipe, approximately 350 ft. from the surface of the ground. This extends to within 3 ft. of the top of the sandstone strata, hermetically sealing the well from all water in the strata above the St. Peter's sandstone. The analysis made from the water secured from the completed well was superior to that of all other wells in the territory, on account of the sealing off of the upper strata.





At the site of this well an air-lift plant was constructed for lifting the water from the well to a small surface reservoir. Thence the water is forced into the mains against 40 lbs. pressure, by means of a centrifugal pump.

The air-lift equipment consists of one angle-compound compressor, with 16 by 9¾ by 12-in. cylinders, arranged with short belt drive and unloading valve; one standard 5-in. foot-piece (outside air line), and well-head with umbrella separator; one 42-in. by 8 ft. vertical steel air receiver; and one 100 h.p. motor.

Following are the conditions of operation and the results of the test on the well:—

Depth of well, 1,252 ft.

Water pipe in well, 235 ft. of 5-in., 331 ft. of 6-in.

Main air pipe in well, 235 ft. of 2-in., 331 ft. of 2½ in.

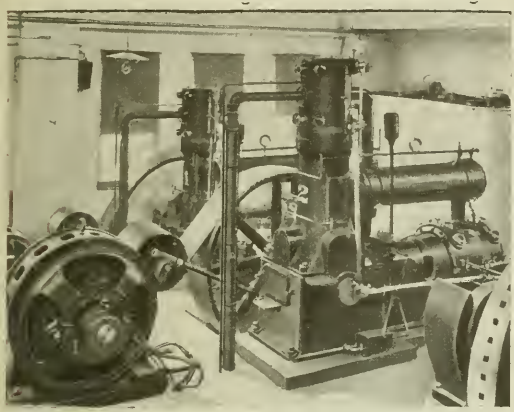
On account of the severe drop, an auxiliary starting device was installed at a depth of 481 ft. 8 ins., to pump off the head and keep the starting pressure within the range of the compressor.

Static head (from ground)	186 ft.
Drop	118 ft.
Elevation above surface	7 ft.
Total lift	311 ft.
Operating submergence	262 ft.
Percentage of submergence	45.8
Depth of pump in well	566 ft.
Operating pressure	121 lbs.

At the Left,—Air Lift Pump; Above,—Typical Arrangement of Air-Lift, Including Pump, Booster, Elevated Tank and Compound Lift

Starting pressure with auxiliary	129 lbs.
Gallons per minute pumped	450
Actual cu. ft. free air used per min.	450
Revolutions of compressor	179
Water h.p. (that is, ft. lbs. of work done)	35.5
Operating horse-power	94
Efficiency, per cent.	37.5

The efficiency shown is considered excellent, and this result was made possible by careful proportioning of the sizes of air and water piping, proper location of the footpiece or pump in the well, and by the use of improved footpieces, providing a continuous flow of water. In this design the air is discharged from the footpiece into the water in the well casing in a multitude of fine jets, creating a very thorough mixture or emulsion of air and water. This action



Compound Air Compressors, with Short-Belt Motor Drive, at Maywood Water Works

secures the maximum efficiency, as the chance of slippage is reduced to the minimum.

The figures on the second plant, known as the Bradley Well No. 2, are as follows and are taken from a test on March 8th, 1919:—

Depth of well, 1,245 ft.

Diameter, 360 ft. of 15-in., 250 ft. of 14¼-in., 635 ft. of 13½-in.

Water pipe in well, 204 ft. of 8-in., 213 ft. of 7-in., 190 ft. of 6-in.

Main air line, 600 ft. of 3-in.

Auxiliary line, 500 ft. of 1½-in.

Conditions of operation:—

Static head from ground	190 ft.
Drop	157 ft.
Elevation above surface	7 ft.
Total lift	354 ft.
Operating submergence	253 ft.
Percentage of submergence	41.75
Depth of pump in well	600 ft.
Operating pressure	115 lbs.
Shut-in pressure	110 lbs.
Starting pressure with auxiliary	135 lbs.
Gallons per minute pumped	650
Actual cu. ft. free air used per min.	719
Displacement	883
Revolutions of compressor	214
Water h.p. (that is, ft. lbs. of work done)	58.2
Operating air h.p.	148
Efficiency of air compressor compared to work done, percentage	39.3
Estimated in-put efficiency, percentage ..	35.8
Estimated motor efficiency, percentage ...	91

Attention is called to the advantage of air-lift pumping in the case of wells, the waters from which, in order to make them suitable for domestic or other purposes, require treatment for the elimination of sulphates or carbonates of iron in solution, or other impurities which can be oxidized and precipitated by aeration and then removed by filtration.

In this method of pumping the compressed air is forced into and comingled with the water at the bottom, or at least deep in the well, by means of a multiplicity of fine streams or jets, ensuring the most intimate mixture of the air and water, every particle of the water being permeated with air as it rises in the eduction pipe. Oxidation and precipitation of the iron solution thus takes place with the greatest possible rapidity, and it is then a simple matter to remove it by filtration. Waters containing carbonate of iron are especially susceptible to treatment in this manner, the pumping operation at the same time serving the purpose of freeing the dissolved iron so that it may be removed by the filter without even intermediate sedimentation.

The treatment of waters containing sulphates of iron are more difficult, and the use of ample sedimentation tanks or basins ahead of the filter are advisable. In some cases aeration must be supplemented by the feeding of a very small quantity of lime into the water to accelerate sedimentation, but in any event the thorough aeration of the water in the pumping operation is a very important and vital adjunct to the purification process.

Combined air-lift pumping and purification plants can be arranged in many different ways, according to local conditions. In some cases the air-lift merely delivers the water to a sedimentation tank combined with a filter located at the surface and as close to the well as practical, the effluent from the filter flowing by gravity to a surface reservoir or sump, whence it is forced by piston or centrifugal pumps into the service system, or to a service tank or reservoir located at a suitable elevation.

In other cases, where the well or wells are deep enough to provide the necessary submergence, and other conditions are right to utilize the air-lift (by means of an air-lift booster and re-lift jet) to lift and force the water in one operation from the wells to the elevated storage reservoir, this reservoir or tank also acts as a sedimentation tank, and the water can pass from it through a pressure filter into the service pipes.

A third arrangement is where the pressure filter is placed in the line between the well and the elevated reservoir, and the water lifted and forced by the air-lift in one operation from the well through the filter and up to the elevated service reservoir.

I would like to call special attention to the two latter arrangements as it is my observation that the possibilities of the air-lift, as a means of forcing the lifted water to a point beyond the well-top, are not generally realized. While this method has its limitations, there are many situations where it can be used to advantage, eliminating the complication of a separate pump, with its incidental surface suction-basin for this service.

In the boosters generally used in these installations the discharge from the well is brought to a complete stop by striking an umbrella separator in the booster throwing the water to the bottom of the booster and allowing the air to escape from the top. Owing to the complete emulsion of the air and water, considerable of the air is carried over in the discharge from the booster, and, while this is of benefit where filtration is to be used as above described, it becomes detrimental where this class of booster is discharged into long horizontal lines, on account of the air pocketing in the high points, and also where the discharge is to be carried directly to pumps or condensers.

In order to overcome the difficulties above mentioned, and to ensure perfect separation of the air and water, a separator has been designed which consists of a simple shell, or cylinder, with top and bottom. The combined air and water is discharged into the top and at one side, at a tangent to the periphery, under high velocity from the well, causing it to swirl, and effecting a perfect separation of

the air and water, the water leaving the separator from an outlet at the bottom, tangent to the periphery, and the air passing off at the top. The downward centrifugal action leaves the air quite dry and frees the water entirely from air bubbles.

By this centrifugal arrangement the water is not brought to a dead stop and reversed, with consequent loss of all momentum, as in some older types of boosters, but its direction is gradually changed so that it is carried on to the outlet of the separator without loss of momentum and with proportionately greater efficiency.

PENETRATION "SLIDE RULE"

TO facilitate the determination of the proper penetration of asphalt for various classes of paving, J. R. Draney, sales manager of the United States Asphalt Refining Co., of New York, has devised a "slide rule" which gives the correct answer at once for any given condition. This "rule" is patented and has been manufactured in celluloid by Mr. Draney's company, and is being distributed gratuitously to paving engineers and road contractors. It is very neatly arranged and forms a handy paper weight as well as a ready means of determining penetration.

The "rule" is circular, 4 ins. in diameter, about ½ in. thick and weighs 7½ oz. There are three circular, concentric scales, the inner two having openings through which the readings are taken.

The outer scale is fixed, the circle being divided into four portions, covering (1) asphaltic concrete (Topeka), (2) asphalt macadam (hot mix), (3) penetration construction and (4) sheet asphalt.

The middle scale can be revolved so as to be placed in proper adjustment with the outer scale. The middle scale is divided into three parts: (1) high temperatures, (2) moderate temperatures, and (3) low temperatures.

The innermost scale also revolves, and likewise is divided into three parts, (1) heavy traffic, (2) moderate traffic and (3) light traffic.

The instructions for using the "rule" are as follows:—"Select the quadrant or the outer dial showing the type of construction, then turn the intermediate dial until appropriate temperature conditions are in register. Now turn the centre dial until the sector showing the proper traffic conditions registers with the two outer sectors. The number appearing in the opening in the quadrant originally selected is the number or grade of asphalt to be ordered."

Following are all the readings that can be obtained from the rule:—

Pavement	Temperature	Traffic	Penetration Grade No.
Asph. Conc.	High	Heavy	55
"	"	Mod.	55
"	"	Light	55
"	Mod.	Heavy	55
"	"	Mod.	55
"	"	Light	65
"	Low	Heavy	65
"	"	Mod.	65
"	"	Light	75
Asph. Mac.	High	Heavy	65
"	"	Mod.	75
"	"	Light	75
"	Mod.	Heavy	65
"	"	Mod.	75
"	"	Light	75
"	Low	Heavy	75
"	"	Mod.	75
"	"	Light	85
Penetration	High	Heavy	85
"	"	Mod.	85
"	"	Light	85
"	Mod.	Heavy	110
"	"	Mod.	110
"	"	Light	110
"	Low	Heavy	150
"	"	Mod.	150
"	"	Light	150
Sheet Asph.	High	Heavy	45
"	"	Mod.	55
"	"	Light	55
"	Mod.	Heavy	45
"	"	Mod.	55
"	"	Light	55
"	Low	Heavy	55
"	"	Mod.	55
"	"	Light	65

The permissable variations in penetration of the different grades of asphalt are given as follows:—

Grade No.	Range in Penetration
45	40 to 50
55	50 to 60
65	60 to 70
75	70 to 80
85	80 to 90
110	100 to 120
150	130 to 170

SUPPLEMENTARY ESTIMATES

SIR Thomas White, Minister of Finance, announced on Thursday, July 3rd, in the House of Commons, supplementary estimates, amounting to $36,723,120, of which $23,494,256 will be charged to current revenues and the remainder to capital account. Following is a partial summary:—

Harbor Work	
Champlain, drydocks	$ 207,000
Collingwood, breakwater	50,000
Depot Harbor, wharf	34,000
Esquimalt, drydock	500,000
Fraser River, dredging	50,000
Hamilton, harbor improvements	100,000
La Prairie, Que., protection	82,000
Little Current, wharf	54,000
Nicomen Island, improvements	36,000
Owen Sound, wharf	86,000
Port Arthur and Fort William, harbor improvements	200,000
Port Dover, harbor improvements	50,000
Port Stanley, harbor improvements	33,000
River St. Charles, improvements	55,800
Shipbuilding	10,000,000
St. John, harbor improvements	250,000
Sydney, N.S., wharf	100,000
Thessalon, breakwater	48,000
Toronto breakwater protection	200,000
Toronto, harbor improvements	200,000
Vancouver, harbor improvements	18,000
Victoria, harbor improvements	21,000
Bridges	
Edmundston, N.B., across St. John River	$ 25,000
Hamilton, across Burlington Channel	100,000
Railway Construction	
Edmonton, Dunvegan and British Columbia subsidy—Spirit River through Grand Prairie	$ 258,797
Hudson Bay	300,000
Quebec and Saguenay	550,000
Public Buildings	
Kamloops, B.C., postoffice, etc.	$ 20,000
London, Ont., postoffice, etc.	400,000
Montreal, postoffice	24,000
Oshawa, Ont., postoffice, etc.	23,000
Portage La Prairie, Man., improvements	25,000
St. Catharines, additions	28,000
Toronto, postal station A	115,000
Winnipeg, postal station A	10,500
Miscellaneous	
Federal Department of Health	$ 200,000

WORLD'S MOST POWERFUL PRIME MOVER

Is Triple, Cross-Compound Steam Turbine Installed in New York Power-House—Rated at 70,000 k.w. Capacity for Two Hours

By A. B. Cole
Westinghouse Mfg. Co., Pittsburgh, Pa.

In its 74th St. power-house, the Interborough Rapid Transit Co. of New York recently placed in operation a turbine that is remarkable for two reasons. In the first place, it is rated at 60,000 k.w. capacity continuously, and 70,000 k.w. for two hours, so it is the most powerful prime mover in the world. Secondly, it has three elements—one high pressure and two low pressure, and is the first triple cross-compound turbine to be placed in operation.

The purpose of this huge machine is to assist in meeting the greatly increased demand for transportation in New York City, due to the opening up of a new subway system, and the extension of the service of the existing subway, elevated and surface lines.

The rapidity with which the Interborough's power requirements have increased in the past few years is indeed extraordinary. In 1904, the 74th St. station contained nine reciprocating engines driving direct-current generators rated at 5,000 k.w. each. This amount of power sufficed for a while, and then in 1913 it became necessary to remove four of these engines and install in their place three compound 30,000 k.w. turbines.

Though 90,000 k.w. was thus substituted for 20,000 k.w., this increase was hardly obtained when it in turn became insufficient. Now 70,000 k.w. more is added, and probably additional units will again be needed in the not distant future.

The new unit occupies a floor space of 52 by 50 ft., and is about 19 ft. high. The high pressure element receives steam at 205 lbs. gauge pressure, and superheated 150° F., and exhausts it into the low pressure elements at 15 lbs. gauge pressure. The two low pressure elements are identical in construction, and each receives one-half of the steam from the high pressure element and exhausts it into the condenser where a 29-in. vacuum is maintained. All three elements operate at 1,500 r.p.m., and each drives a generator rated at 20,000 k.w. continuously, 23,500 k.w. for two hours, and 30,000 k.w. for a half hour. The generators deliver three-phase, 25-cycle, 11,000-volt alternating current.

Though consisting of three separate elements, the entire machine is started, synchronized and controlled as a single unit. At the same time, any one or two of the elements can be shut down without interfering with the remainder, so that the high efficiency of a single large machine is combined with the flexibility of three smaller machines. In addition, the three small elements are mechanically much stronger than a single large one would be; the temperature differences in any cylinder are considerably less, and commercially common materials, with moderate blade speeds and stresses, can be used.

Close-Up View of the Triple Compound Turbine

All of the turbines are of the pure reaction type, without the usual impulse elements, as this construction is considered preferable in view of the great volumes of steam to be handled. The high pressure turbine is of the single-flow type, and is made of of cast steel. The low pressure turbines are of the semi-double flow type; that is, the steam enters near the centre of the turbine and flows as a whole through a portion of the blading, and then divides into two portions, each of which flows through a separate section into the condenser. Since the low pressure turbines must receive high high pressure steam in case the high pressure turbine is shut down, the central portions of these turbines are made of cast steel also. All three rotors are equipped with thrust bearings in order to prevent axial movement.

The generators are so connected to the bus bars that any combination of them can be operated in parallel. In practice, however, all three are brought up to speed together, and synchronized through a single oil-switch connecting the generator busses to the main bus. Reactance coils are installed between the various busses, which limit the amount of current that can flow between the generators. Should a short circuit develop in any of the feeder circuits, or a burn-out occur within a generator, the generator affected is disconnected from the busses by a circuit breaker without interfering with the operation of the other generators.

The method of synchronizing the generators is as follows:—

60,000 k.w. Triple Compound Unit Furnishing Power for Subway, Surface and Elevated Railways of New York—70,000 k.w. Capacity for Two Hours

INTERBOROUGH RAPID TRANSIT CO.'S 74TH ST. POWER HOUSE—30,000 K.W. CROSS-COMPOUND UNIT IN FOREGROUND, NEW TRIPLE COMPOUND UNIT IN CENTRE, AND OLD 5,000 K.W. ENGINE-DRIVEN UNITS IN REAR

The field current is first applied to all of the generators, and then the throttle valve of the high pressure turbine is partly opened. As soon as the high pressure rotor starts revolving, it will start the rotors of the low pressure turbines through the field current. All three then come up to speed together in correct phase with each other. They are then synchronized with the system and connected to it by closing a single circuit breaker.

The governing mechanism must not only control the unit as whole, but also each turbine operating separately. Some of the operations performed by the governors are as follows:—

If serious electrical trouble develops on the circuit of one of the generators of the low pressure turbines, a circuit breaker will disconnect this generator from the bus bars. Relieved of load, the turbine begins to speed up, but before its speed has increased 4%, its governor shuts off the steam supply from the high pressure turbine. This, of course, raises the back pressure of the high pressure turbine, and a back-pressure valve opens, allowing part of the exhaust from the high pressure turbine to pass into the atmosphere while the remainder goes into the other low pressure turbine.

In the meantime, the first low pressure turbine, being without steam, shuts down. When its speed reaches 3% below normal, the governor admits high pressure steam, and the turbine continues to operate at this speed until the switchboard operator either shuts it down or restores normal conditions.

Should the generator of the high pressure turbine be cut out of circuit, the governor cuts off practically all the steam to the entire system, leaving just a sufficient flow to maintain the speed of the high pressure turbine now without load. The speed of the two low pressure turbines decreases, and when the frequency drops 3%, the governor admits high pressure steam direct to the low pressure turbines, which then continue operating. The switchboard operator can now either restores matters to normal or shut down the high pressure turbine.

Each turbine also has an emergency stop which will operate automatically in case the governor fails and the turbine begins to race, or it can be tripped by the switch board operator.

When one of the turbines fails with the entire unit heavily loaded, the governors permit each of the remaining turbines to carry the maximum load of 30,000 k.w. This can be maintained for a half hour, which is regarded as sufficient time to get other generators into operation, and thus relieve the overloaded turbine.

The condenser equipment consists of two 25,000 sq. ft. surface condensers for each low pressure turbine. There are four circulating pumps, three Le Blanc air pumps and four condensate pumps. All of these pumps are turbine-driven (the air pumps directly and the others through gears), and all are so arranged that one or more can be put out of service without interfering with the operation of the condenser.

The steam consumption of the entire unit at its point of best efficiency is 10.7 lbs. per kilowatt-hour. The pressure turbine and one low pressure turbine, operating together, consume 12 lbs. of steam per k.w.h., and one low pressure turbine alone consumes 14.25 lbs. The total steam consumption at full load is 826,000 lbs. per hour.

LARGE STEEL INDUSTRY FOR TORONTO

ACCORDING to information given out by R. Home Smith, Toronto is to have a steel and metal plant on the site of British Forgings at Ashbridges Bay, with a capital of $3,000,000. Mr. Smith said: "After much trouble and negotiating we have persuaded Messrs. Baldwins, of Swansea, Wales, to found a plant of steel sheets and other metal products, valued at between $2,000,000 and $3,000,000, on the site of the British Forgings. At the initial stages 2,000 men will be employed, and there is no reason to doubt that ultimately employment will be given 10,000 men."

EDMONTON PUBLIC UTILITIES IMPROVING

EDMONTON public utilities show a net surplus for May of $2,345, compared with a net deficit for the same month last year of $3,549. The net surplus for the five months (inclusive of the street railway deficit) amounts to $62,233, against $33,809 for the corresponding period of 1918. Net surpluses for the five months of the respective departments are as follows:—

	1919.	1918.
Electric light	$ 66,056	$54,131
Telephone	21,356	13,845
Waterworks	14,246	10,746
Total	$101,659	$78,724

The street railway deficit is $39,425, as compared with $44,914 last year, leaving, as already stated, a net surplus of $62,233 on the combined utilities, as compared with $33,809 in 1918.

THE RELATION OF DEPRECIATION TO INVESTMENT*

By W. C. Hawley
Chief Engineer and General Superintendent, Pennsylvania Water Company

THIS is a subject which, until recently, has received very little consideration from the management of most of our water companies. It was looked upon as theoretical, rather than a real thing seriously affecting the finances of the companies. Not many of our accountants and managers knew how to compute depreciation and very few water companies actually created and maintained a depreciation or replacement fund. We are only beginning, under public regulation, to realize the vital necessity of doing so.

Those of us who have owned automobiles for a few years have received practical and personal demonstration of the reality of depreciation. The machine that cost $2,000 last year can be insured for only $1,500 or less this year, and in from three to five years it must be replaced by a new one. It goes as part of the game; and when a new car is necessary, we will write a cheque or mortgage the house and pay no more attention to it. But suppose by way of illustration, that a man in moderate circumstances invests his savings, and perhaps some money which he has to borrow, in an automobile and starts to operate a jitney or express route. Let us assume that he has no bad luck or accidents and that his earnings are sufficient to pay for gasoline, oil and repairs and give him and his family a living. At the end of five years we will assume that the jitney has to be scrapped. Then, unless the owner has been setting aside from his earnings year by year a proper amount of money as a depreciation fund, he finds himself worse off than when he started. He has nothing to represent the savings which he put into the machine and the money he borrowed. His "plant" has been wiped out. He has no fund to replace it, and if he is to continue in business he must find new capital. This is only an illustration, but the principle is as true and operates as surely in the case of the property of a water works company or any other utility as it does in the illustration given. It is not only recognized in our public service company laws, but, as we shall see, public service companies have been severely penalized in the past because they have not provided depreciation or replacement funds.

Definition of Depreciation

It is not necessary to consider carefully worded definitions of depreciation. Our chief difficulty is that the word has been used with so many different meanings. Depreciation as it affects us, is the reduction in value of our plants, due to age or change of conditions. There are various ways of estimating it, as the "straight line" method, "the sinking fund" method, the "equal annual payment" method, etc. When estimated for the period of one year it is spoken of as "annual depreciation," and when this depreciation is summed up for a period of years equal to the age of the unit considered, or the average age of the plant, we arrive at what is known as "accrued depreciation." Subtracting accrued depreciation from the original value of the plant, however that may have been computed, gives us the depreciated or present value of the physical plant.

What have we been doing in the past regarding depreciation? Many of us nothing, and most of us who have done anything have merely "charged off" depreciation. That is, year by year a certain amount has been added to the operating expenses and either the plant account reduced that much or a corresponding liability set up which was equivalent. Thus year by year the assets of our companies have been reduced and unless, through excessive dividends an equivalent amount was returned to the stockholders, there has been no return to them of that portion of the original investment. In many cases the amount charged off as depreciation has been left in the business and practically it has been reinvested in the plant. The author will discuss this situation later.

The practical result of not creating a depreciation or replacement fund has been that when water works plants have been valued by the public service commissions, the historical cost has been determined where possible and also the cost of reproduction new, and from these and other considerations the value of the plant has been determined and from that figure the accrued depreciation has been subtracted. The Pennsylvania Public Service Commission, in the Beaver Valley Water Co. case, subtracted an accrued depreciation of $215,175.11 from a "fair value new" of $1,187,286.11, which included, however, depreciable property to a value of $1,132,500.60. In the Ohio Valley Water Co. case $88,661 accrued depreciation was subtracted from the reproduction cost of $1,083,825 (which included $10,000 working capital) while from the original cost of $841,343 accrued depreciation of $58,149 was subtracted. In the Westmoreland Water Co. case, from an original cost (including working capital of $10,000) of $1,266,292.51, accrued depreciation amounting to $185,701.85 was subtracted. This was the amount of depreciation which had been charged off on the books of the company and which had been estimated upon a valuation much higher than allowed by the commission, but it was not reduced accordingly. From a reproduction value of $1,373,904.54, estimated accrued depreciation of $122,641 was subtracted. Thus we see the original investment reduced from 5 to 19 per cent.; although not one dollar of this original investment has been returned to the stockholders. In the Westmoreland Water Co. case, counsel for the Water Co. attempted by argument to convince the public service commission that such a reduction was unjust. As a matter of fact, the money had not been taken out of the business, but had been invested in new plant to meet the public's demands for additional service. The practical condition was no different from what it would have been if the company had established a depreciation replacement fund by paying to a trustee or commissioner the amount charged off annually to depreciation and borrowing that money from the trustee, giving therefor the company's note and paying interest upon the money so borrowed. In a substantial water company this is probably one of the best methods of handling a depreciation fund. The answer of the commission to this argument was as follows:—

"The argument that the money represented by these charges remained in the plant for the benefit of the public service is not convincing. Some of it may have gone into the plant to offset depreciation, but the fact remains that in the past the company has not maintained a depreciation account, but has charged renewals to operating expenses rather than to such a fund. Practically all of these charges must have gone into extensions and betterments, and hence are included in the total original cost as found by the commission. The money has been returned to the stockholders just as surely as though it had been paid to them in cash. They have built extensions and betterments with the money represented by these charges instead of with new capital, and therefore, under the argument presented by the respondent, the deduction is entirely justifiable."

The flaw in this argument is so manifest that it needs little discussion. There had been little, if any, replacement necessary because of depreciation in the plant of the Westmoreland Water Co. Its original reservoirs, supply mains and distributing system were and are still in service. What few minor items had been charged to operating expenses rather than to the replacement fund, if any, could readily have been deducted and the accounts corrected. The commission admits that "practically all of these charges must have gone into extensions and betterments." If such an expenditure can be considered a return to the stockholders, it follows that merely charging off depreciation is not a sufficient compliance with the principles of good accounting, or with what the Public Service Commission considers to be the proper procedure in such a case. The decision of the commission not only wipes out for rate making purposes the cost of additions to plant since it was originally built, to the amount of the accrued depreciation, but it leaves the water

*Read before the Pennsylvania Water Works Association.

company without a depreciation or replacement fund. To demonstrate this statement let us put the facts into the shape of a formula, assuming that a depreciation fund had been created:—

Let P = original cost of plant.
Let A = additions to plant paid for from charges to depreciation.
Let a = additions to plant paid for by capital other than from charges to depreciation.
Then $(A+a)$ = total cost of additions to plant.
Let D = accrued depreciation.
Let F = depreciation or replacement fund.
Let I = total investment.

Then we will have

$$I=P+(A+a)-D+F$$

Since D and F are equal, this equation reduces to

$$I=P+(A+a)$$

In other words, the original investment in plant and additions thereto has been maintained. Since no fund has been created, the Public Service Commission says:—

$$I=P+(A+a)-D$$

Assuming that the amount D has been completely expended in additions A
we have

$$A=D$$

and hence

$$I=P+a$$

This shows clearly that the company's investment has been reduced by the amount of depreciation charged off, and that the company has no asset to offset this loss. Surely this is not justice and does not accord with the decision of the United States Supreme Court in the Knoxville Water Co. case which is quoted later.

Setting Aside of Depreciation

Sound business principles require the setting aside of depreciation. The Pennsylvania Public Service Law provides, Article II., Section 1 (i):—

"It shall be the duty of every public service company to carry a proper and reasonable depreciation account, if required so to do by the order of the Commission."

And also (Article V., Section 15):—

"The Commission may, and shall after hearing had upon its own motion or upon complaint, establish by an order to be served, as hereinafter provided, upon every public service company affected thereby, a system of accounts to be used by such public service companies: and may also in its discretion prescribe the manner and form in which accounts, records and memoranda shall be kept by public service companies, including the accounts, records and memoranda of the conveyance of passengers and property and a proper and reasonable depreciation account, . . ."

Uniform System of Accounting

In carrying out these sections of the law, the Public Service Commission under date of March 25, 1918, prescribed and issued a uniform classification of accounts for water companies, in which it provides for the keeping of an account to be known as "Depreciation of Structures and Equipment Reserve." This is on the asset side of the balance sheet, is a subtractive account and is identical with what has been generally carried as "Accrued Depreciation" on the liability side of the balance sheet. The Westmoreland Water Co. was, therefore, carrying a depreciation account such as water companies are now required by the Public Service Commission to carry, and yet the assets of the company were reduced by the amount of that account with no offset, and this was justified by the claim that the money had been returned to the stockholders because it had been invested in extensions and betterments to the plant. Of course, in obtaining the value of the physical plant it was perfectly proper to subtract the amount of accrued depreciation. The gradual reduction in the value of the plant because of depreciation is a fundamental fact, but if the original investment is to be maintained intact, there must be a corresponding asset equal in amount, and this is the depreciation or replacement fund.

By way of illustration of what this may mean to the investors in a water works enterprise, let us assume that the original cost of a plant is $1,000,000, and we will consider that no additions are made to the plant, also that it is a pumping plant of ordinary construction, and that to create a proper depreciation or replacement fund to be invested on a 4 per cent. sinking fund basis, 1 per cent. per year of the original cost of the plant must be set aside. This means an average life for the plant of about forty-one years. Under these assumptions the amount in the replacement fund at the end of each year would be as follows:—

First year	$ 10,000
Second year	20,400
Third year	31,261
Fourth year	42,465
Fifth year	54,163
Sixth year	66,330
Seventh year	78,983
Eighth year	92,142
Ninth year	105,882
Tenth year	120,061
Fifteenth year	200,236

These figures are based upon the assumption that there had been no replacements made. This would probably be true for the first ten or twelve years, and we might then reasonably expect replacements requiring money to be taken from the replacement fund. If, however, at the end of fifteen years this company met with a rate case requiring the valuation of its plant, it will find its plant value reduced by 20 per cent. of the original investment, and according to decisions up to the present, unless it has the equivalent funds in a depreciation or replacement fund it has nothing to offset this loss. This is, of course, upon the assumption that the earnings of the plant have not been excessive and hence there has been no return of this amount, or any part of it, to the stockholders.

Against this method of valuation we have the decision of the Supreme Court of the United States in the case of Knoxville vs. Knoxville Water Co.:—

"A water plant with all its additions, begins to depreciate in value from the moment of its use. Before coming to the question of profit at all, the company is entitled to earn a sufficient sum annually to provide not only for current repairs but for making good the depreciation and replacing the parts of the property when they come to the end of their life. The company is not bound to see its property gradually waste, without making provision out of its earnings for its replacement. It is entitled to see that from earnings the value of the property invested is kept unimpaired, so that at the end of any given term of years the original investment remains as it was at the beginning. It is not only the right of the company to make such a provision, but it is its duty to its bond and stockholders, and, in the case of a public service corporation at least, its plain duty to the public."

Reproduction Cost Less Depreciation

Surely nothing could be plainer than that, and yet, in decision after decision of the various State Utility Commissions, accrued depreciation has been subtracted without any regard to whether or not it has ever been earned, or if earned it has ever been returned to the stockholders.

Arguments in the effort to convince commissions of the correctness of this theory have been made so often, only to be ignored, that it seemed almost as hopeless as the effort to convince the commissions that "going value," "cost of establishing business," or "the value of established business," —whatever one chooses to call it—has a separate and distinct cost and value over and above that of the physical plant. It was, therefore, with surprise and pleasure that the author noted the decision of the Wisconsin Railroad Commission handed down June 1, 1918, in the case of the Milwaukee Electric Railway and Light Co., *et al.*, vs. City of Milwaukee. (P.U.R. 1918-E.) In this decision the commission says:—

"(11) As reproduction cost new is not necessarily to be taken as representing fair value, it seems equally clear that reproduction cost new less depreciation cannot be so taken. What is to be ascertained is the amount fairly representing the prudent and honest investment made by the owners of the utility. They are entitled to have that contribution kept intact until returned to them. In other words, those that have contributed to the utility are, under normal conditions, entitled to a fair return on the amount of such investment while it remains in the utility. Whether that sum be arrived at on the original cost (physical property) or investment basis (and the two may be identical) the investor is entitled to a return on this amount, assuming that no part of his investment has been returned. If this amount, on the other hand, is taken as fairly represented by reproduction cost, the same principle would seem to apply; for reproduction cost less depreciation does not of itself establish the return of any part of the investment to the investor. Reproduction cost new less depreciation can be used as the final measure of fair value for rate making purposes only upon the assumption that the utility has not only earned the sum represented by depreciation in excess of a fair return on the original investment, but has also returned the same to the investors, retaining no depreciation reserve represented by assets. Where reproduction cost less depreciation is used as controlling in determining fair value unless the amount earned to provide for depreciation is returned to investors, it will not usually earn a return sufficient to constitute a fair return on the investment. Where the reserve is provided on a straight-line basis and retained by the utility, any interest earned on assets offsetting the reserve would constitute income of the utility. If the reserve assets are held in the business and the reproduction cost less depreciation is used as a basis for the valuation, a return upon such reproduction cost less depreciation at the normal rate, plus interest earned upon reserve assets, would be less than a fair return upon the investment unless a rate of interest were actually earned upon such reserve assets equal to the rate which constitutes a fair return for the property as a whole. Where reserve assets actually earn less than a fair rate of return upon the investment as a whole, the only way that occurs to us in which investors can obtain a fair return upon their full investment is by earning a higher rate on the cost new less depreciation than would be required if the investment, as already discussed, were used as a basis. Unless the rate of return on the cost new less depreciation is to be enough higher than the rate which should be applied to the investment to bring the total return, which is made up of the return on cost new less depreciation and interest earned on reserve assets, the reserve being provided on a straight-line basis, up to an amount which would constitute a fair rate of return on the investment, we see no way in which the investor, under such a method of valuation would secure a fair return on this investment, unless it is to be assumed that amounts earned for depreciation can be withdrawn from the business and the investment thereby diminished. This principle was fully established in the Knoxville Water Co. case."

Then follows the quotation from the Knoxville case which has been given above.

Understanding of Principles Involved

This is the clearest statement of the principles under consideration that we have seen, and gives evidence that not only are we progressing toward a full understanding of the principles involved in valuation and rate regulation, but that our public service commissions, when convinced of the correctness of a principle, will deal justly with the public service corporations, even to the extent of reversing rulings laid down in former decisions. We may be dissatisfied with some of the things which the commissions have done, but let us remember that they and the utilities are working out a comparatively new proposition which promises much good both for the public and the utilities. We are traversing a path which has only been charted by broad statements of principles in the few legal decisions which have been handed down in such cases. Our courts in the few rate or valuation cases reported have avoided criticism by not giving the details of the calculations by which they arrived at values. Some such statement as "taking into consideration this and that and all of the other matters which bear upon this question, we find so and so" has protected many a valuation from an attack which should have resulted in reversal by the higher courts. The commissions, however, as a rule have wisely adopted the plan of publishing the calculations by which they arrive at values. Some of the calculations are simple and the principles well understood and agreed upon. Others are involved, difficult of determination, with at least some of them still the subject of doubt and disagreement. Depreciation and its treatment in accounting and in valuation and rate making has been one of these. This Milwaukee decision is a milestone on the road of progress.

Definition of Reserve

In the uniform classification of accounts for water companies, prescribed by the Public Service Commission of Pennsylvania, to which previous reference has been made, we find that fixed capital has been divided into two accounts—that installed prior to January 1, 1918, and that installed since December 31, 1917, the latter having been classified in accordance with prescribed accounts, and that the next account, No. 102, is called "Depreciation of Structures and Equipment Reserve." This, as previously explained, is a subtractive account, and in most of our bookkeeping has been called "Accrued Depreciation," and carried as a liability. This liability has been brought to the other side of the page and made a "red asset," by the same principle as that involved in algebra when we take a quantity from one side of the equation to the other, by changing its sign, and do not affect the correctness of the equation by doing so. This is something new to most of us, but it is quite generally approved by expert accountants and is already in use by a large number of our great industrial corporations. The advantage of it is that, by subtracting the account from the total of the fixed capital, there is shown at once the present or depreciated value of the physical plant. The use of the word reserve in this sense is probably unfortunate. The Century Dictionary defines reserve as: "That which is reserved or kept for other or future use; that which is retained from present use or disposal." The fund which is accumulated and set aside to pay for replacements is a reserve or reserve fund, but it is not clear how the accumulated losses in value due to depreciation can be called a reserve. However, the account known as "Depreciation of Structures and Equipment Reserve" is clearly explained in the printed text accompanying the uniform classification.

This explanation states that there is to be credited to this account and charged to account No. 402, "Depreciation," that amount which it is estimated will, through regular application, over the life of the structures and equipment of the various divisions of the utility water system, be sufficient to provide an adequate reserve to cover those expenses of depreciation that accrue upon such structures and equipment. This, and what follows, is clear and easily understood, but unfortunately neither here nor elsewhere do we find any statement regarding a depreciation or replacement fund, and yet, as we have seen, water companies have been practically penalized because they had not established such funds. It would seem as though there should have been provided a special place under the asset accounts for this fund. Inquiry of the Bureau of Accounts and Statistics was answered to the effect that the proper procedure in creating a fund would be to charge account No. 113, "Insurance and Other Reserve Fund Assets," subaccount—"Depreciation Reserve Fund," and to credit account No. 117—"Cash." In other words, the amount charged to depreciation each year is to be taken from cash and put into a depreciation reserve fund or a depreciation replacement fund, which fund is to be carried as a subaccount under account No. 113.

William Morse Cole, in his book entitled "Accounts: Their Construction and Interpretation," gives (page 84) three sample balance sheets, showing methods of treating depreciation, as follows:—

Assets	Balance Sheets		Liabilities
	First year—all plans		
Plant	$90,000	Stock \ Bonds /	$90,000
	Second year—Plan I.		
Plant	$80,000	Stock \ Bonds /	$90,000
Depreciation fund ..	10,000		
	Second year—Plan II.		
Plant	$90,000	Stock \ Bonds /	$90,000
Miscellaneous assets increased	$10,000	Depreciation	$10,000
	Second year—Plan III.		
Plant	$80,000	Stock \ Bonds /	$90,000
Miscellaneous assets increased	$10,000		

Plan II. he calls objectionable and Plan III. seems even worse, and yet most of us have been using either one or the other of them. Commenting on them Cole says:—

"To summarize what has been said of the depreciation fund, then, we find that it may appear on the balance sheet in one of three combinations: (1) among assets only—in which case specific property is set aside to replace or repair machinery, or buildings, or what not, that are thought to have suffered actual depreciation; (2) among both assets and liabilities—in which case specific property is set aside from net income as a safety fund for possible depreciation not thought to be actual; (3) among liabilities only—in which case the amount is deducted from net income and shown on the books as a safety fund for replacement purposes, but the actual property is left among the general assets without specific designation. In the first case the fund could not be distributed to stockholders without impairing capital; in the other two cases the policy might be changed and the fund distributed without affecting capital, though such distribution might be morally and legally unjustifiable as a violation of implied faith."

Straight Line or Sinking Fund?

Our Public Service Commission has adopted Plan I,. and has improved on it by showing plant or fixed capital at its original amount from which is to be subtracted the accrued depreciation, account No. 102, and the depreciation or replacement fund appears as a subaccount of account No. 113.

There is much of interest in Cole's book, which might be quoted here, but only the following paragraph will be added:—

"Has it cost the corporation anything to accumulate this fund? If our real estate and plant are wearing out and are profitably employed, it is obvious that they are reproducing themselves in the annual product. It follows, therefore, that, if the corporation cannot take from the annual product and lay aside as a depreciation fund the equivalent of the annual wear and tear of the real estate and plant, it is running down hill. In other words, that depreciation fund was created, day by day, in the regular product of the business. Real estate and plant, by constant use, have been slowly converting themselves from building and machinery into merchandise. It is the business of the accountant to see that that conversion is recognized and recorded. The surest way to keep it clearly in mind is to take the proceeds from the sale of some of that merchandise and set it aside as a special depreciation fund. Such a depreciation of real estate and plant is loss, of course; but it is loss only in the sense that consumption of raw material is loss; it reappears in the form of goods, and a certain part of the product must be recognized in that form as converted depreciation."

From the foregoing it seems evident that a water company in order to maintain its investment at 100% has the right to earn year by year an amount sufficient to offset its loss by depreciation, and its duty to its stockholders and to the public to set this aside in a fund to take care of replacements as they become necessary. Whether the annual amount of depreciation should be based on the "straight line" or "sinking fund" plan is a matter about which opinion has differed. There are cases where the "straight line" plan should be used, but the consensus of opinion seems to be in favor of the "sinking fund" plan. The subject is discusssed by the Wisconsin Railroad Commission in the Milwaukee Electric case with this conclusion:—

"In our opinion a most equitable situation arises where depreciation is calculated and provided on a "sinking fund" basis. The fund should be in the custody of a commissioner or trustee, to be invested by him, subject to call for money with which to make replacements when necessary."

Treatment of Amount Collected for Depreciation

On this subject the Wisconsin Commission in the same decision says:—

"The amount collected for depreciation can be treated in one of several ways. It can be loaned subject to call on very moderate rates of interest, being treated as a special trust fund represented by quick assets. It can be used from time to time to, temporarily at least, finance extensions and improvements. A considerable part of it, however, should at all times be immediately available for the purpose for which it is raised. However treated, it will be drawing some interest whether loaned or temporarily invested in extensions and improvements. Were it to be permanently invested in such extensions and improvements it would theoretically be earning interest at the same rate as the other original investment. As a matter of practice, however, this probably does not happen. As a rule, some time elapses after the expenditure before much additional return is earned on the new property. The fund is subject to be called upon at any time for the use for which it has been laid aside, and such extensions and improvements in a growing concern, at least, are usually financed, before the lapse of any extended period, by the issue of new securities."

In addition to these suggestions it would seem that in the case of a company which is strong financially, the trustee could lend the funds in his hands to the company on its note or notes, at the low rate of interest at which the annual payments have been calculated, reserving a sufficient amount on hand, on deposit or loaned on call, to take care of such ordinary replacements as are likely to occur. If some unusual demand for replacement should be made, the trustee could demand payment by the company of a sufficient amount on its note or notes to meet the demand for cash from the replacement fund. This would seldom occur, and if it did, the company would, in the meanwhile have had the advantage of the use of funds at a low rate of interest instead of having to sell bonds or stock or borrow from bank at bank rates of interest. The time when new capital had to be procured would thus have been deferred.

Right to Return on Replacement Fund

There is one other fact in the consideration of this subject which we must grasp clearly and insist upon. That is that the investor has the right to a reasonable return not only upon the depreciated value of the plant, but upon the replacement fund; for this fund is what maintains his investment at its original amount or value. But, it will be argued: "The fund is earning interest and you are asking a double return on it." The answer to this argument is that because the fund earns interest the annual amount paid into the depreciation fund is less than it would be otherwise, and the interest that the fund earns becomes part of the fund and is not returned to the investor. Both the annual payment and the interest are necessary to create a fund sufficient to make replacements as they are required, assuming that the calculations on which the fund is based are correct. This would not be true if the fund were created on the "straight line" basis, as was pointed out by the Wisconsin Commission in the Milwaukee case. Assume that a plant has cost $100,000. There can be no question of the right of the investors in that plant to earn a reasonable return upon that amount the first year. Suppose that the depreciation amounts to $10,000 in the first year, and a replacement fund of that amount is set aside from earnings. Shall the reasonable return for the second year be based on an investment of $90,000 and this amount reduced year by year? If the balance sheet shows:—

ASSETS *Account number*			LIABILITIES	
100, 101	Fixed capital	$100,000		
102	Depreciation of structures and equipment reserve (red)	10,000		
	Depreciated plant value	90,000	Stock, Bonds	$100,000
113	Depreciation replacement funds	10,000		
		$100,000		

Then the answer is plain.

Since preparing the foregoing, the author's attention has been called to the decision of the Indiana Public Service Commission, Re: United Public Service Company of Rochester, Ind., P. U. R., 1918-F, page 316. In passing upon the matter of depreciation the commission comments as follows:—

"The commission is confronted with the fact that, after five years' operation of the law in Indiana, the intent of the depreciation provisions has not been realized. The practice, both in this state and elsewhere, is to dissipate these moneys.

"In estimating allowances to be made to cover depreciation, the Public Service Commission of Indiana adopts a rate allowance which presupposes that moneys provided to meet deferred depreciation shall not lie idle. Such moneys create the 'depreciation fund.' If this fund compounds itself, then the rate of allowance to cover depreciation may be made lower than otherwise. In other words, a fund so administered means a lower rate to the patrons or consumer than if such fund is not interest bearing. For the utility, the creating of such an actual depreciation fund constitutes an asset that should favorably influence its credit. In times of stress or disaster a utility having such a fund may be able to either borrow from this fund or convert or pledge securities held in such fund, and thus be relieved of heavy discounts otherwise incurred.

"Sound and desirable as is the theory, the practice in this and other states is almost universally different. Depreciation moneys are paid out in dividends or used in other ways. The result is that in many cases the 'depreciation fund' is a meaningless bookkeeping account. There is no reserve fund, though the patrons have provided money for such a fund. The public utility is, instead of being financially fortified, reduced to the practice of merely charging off annually on its books a certain amount of the value of its property, reducing rather than maintaining its property value. Often this is finally reflected in poor service. The consumer who has provided proper funds is penalized in service because of improper administration.

"The appended order provides that this utility shall take out of its revenues—the same as it will take moneys for operation, taxes, interest, and dividends—the money allowed and collected under the law, for depreciation; that it will pay such moneys into a depreciation fund; that such funds shall be held intact and separate at all times; that there shall be paid out of such funds all cost—including labor as well as materials—of replacing depreciation; that the funds shall be administered with proper accounting; that interest on such depreciation funds shall accrue not to the utility, but to the fund; that petitioner itself may, with limitations, borrow from the fund, but in such event shall place in said fund its own obligations, in the form of notes or bonds bearing interest payable to the fund.

"The order does not contemplate that, when depreciation funds are borrowed by the utility itself, there shall be a mere bookkeeping account. In other words, the moneys derived from allowances to cover depreciation that are made in rates are to be regarded as a trust fund provided, as prescribed by law, by those served for the benefit of the utility, but not in reality belonging to it until such moneys are translated into actual plant replacements; and such fund must be handled, at the utility's risk, to the best advantage of the consumers and patrons and stockholders and bondholders."

UNIT PRICE CONTRACTS vs. PERCENTAGE CONTRACTS*

By W. L. Darling

IN construction, one or more of three different methods are employed:—

First, company force;

Second, unit price or an agreed sum, with a provision for a percentage, to be increased or decreased as the cost of the work decreases or increases, compared with the agreed cost;

Third, a percentage based on the actual cost of the work.

In the present state of the art, I think it can be safely assumed that the first method should be used only when the work is too small to contract, or when the local or emergency conditions are such that it is not practical to contract, or when the owner has experts in a certain specialized line that are superior to those of the contractors.

The main question, therefore, is: Shall the second or third methods be used, and if the third, will it affect the art, and, consequently, the public?

Energy the Greatest Asset

To discuss it, it is necessary to examine the effort of the contractor himself. The great incentive is to make money, and it is this incentive that has created his value to the owner and to the public. The overcoming of obstacles, financial as well as physical, has produced energy and versatility that could have been acquired in no other way, and, to my mind, energy is his greatest asset. What use is it if he has all the intellect and physical qualities in existence if he has not the energy to use them?

He must have a knowledge of men and plant; where labor can be readily obtained and the plants available; he must know about his supplies, where they can be obtained and how best transported; he must know the market conditions and have an intimate knowledge of the work to be done.

If the work is done on unit price basis, the owner gets the results of the judgment and the experience of many men and many firms. One will see better where supplies are obtainable; another may have a better plant for the job; another may have a better method of doing the work, and it is the pitting of all these men, one against the other, that the owner gets the advantage of.

By the percentage method a man or firm is selected for managing the work; hence the owner gets the benefit of one man's knowledge, and the wrong man may have been selected. I have known men to make a bid on a piece of work by merely sizing it up, and knowing where the necessary outfits were and the men to whom it could be sublet. If he has made a bad guess, he simply has to find some way or means to back up his judgment. I believe some men become so familiar with work that their guess is as good, if not better, than some men's figuring. At any rate, the difficult tasks that they set for themselves bring out all the surplus energy that is in them, and this is what the owner gets the benefit of, and what he will not get should competitive methods be eliminated.

Turning Loss Into Gain

The contractor working on a unit price basis has not only a reputation, but also his very livelihood at stake. We have often seen a man take work at unit prices so low that a heavy loss seemed inevitable, but by using new methods, new tools and exerting surplus energy, he has been able to turn an almost certain loss into a profit for himself, and a much greater profit for the public, as these new methods can be used on further work and by other men.

Contractors, I believe, can materially improve the art of drawing closer lines between their business and the

*From an address delivered March 27th at an organization meeting of the Northwest Association of General Contractors, St. Paul, Minn.

owner's. Unit prices and specifications should be more definite. The question of custom between contractor and owner should be eliminated. The contractor should have better data on which to base his bid. There has been a growing custom not to pay as much attention to the contract as to customary settlements. I believe that much better results would be obtained if the contractors would insist on the contract and specifications being followed, and if conditions should arise when the intent of the contract would be materially affected by having a definite understanding as to price and conditions before going ahead.

Progress Dependent Upon Incentive

Under past conditions work has been suddenly authorized with no time given either the engineer or the contractor to determine costs or make intelligent bids. A much smaller margin between the estimate and the actual cost of work would result if these conditions could be known. The risk of the contractor would be much smaller, and the owner would have more definite knowledge of what his work would cost.

An agreed price, varying with the percentage, has many good points when the work is simple and conditions are such as to permit of it, but it could not be used very well on railroad work, for instance, unless the conditions were properly determined beforehand; and right here is where the owner or contractor can greatly improve present methods by determining unforeseen conditions.

By the percentage method the contractor has few financial troubles to overcome, no particular inducements except pride to introduce new methods or tools, no sleepless nights to figure out some new scheme for the next day, no surplus energy to exert in himself or employees. The employee, knowing that his superior is not in financial troubles, does not exert himself unnecessarily. The contractor does not, perhaps, try new methods or new tools, as he may think he has no right to risk a failure. On the other hand, the unit price men must take the risk, and bend all their energy to make it successful.

My point is this: That these necessities of the unit price men have produced a personal result that could not otherwise have been acquired, and that as soon as the incentive is eliminated, progress will slow down, if it does not actually retrograde.

There is no question but what there are men doing percentage work that are just as competent and perhaps just as energetic as the unit price men, but I claim that it is because of the state of the art and its personnel, and due to previous efforts of the unit price men.

The main objections to the unit price methods are that in instances contractors make too much money, and that the percentage method will eliminate that danger.

Frequently, a large profit is due to the fact that a contract was taken on a high market and the work done as the market fell. If the reverse condition obtained, there would have been a loss and no comment made.

Unit Prices Decreasing

It has seemed to me the best way to determine the amount of money made by contractors is to consider the work done here in the Northwest for the last forty years, and then to determine the wealth of the various men who have been engaged in that business during that time, and who have not made their money elsewhere. While it is true, perhaps, that in individual cases owners have to pay larger sums than by a percentage method, I do not think it is generally true.

It seems to me that the great results of the unit price method is the fact that during the last forty years, under normal conditions, unit prices have decreased in the face of rising values of labor and material, and have produced a class of men who, when the emergency came, were able to accomplish things that did not seem possible. If you give up the unit price or competitive methods, it is going to result in one of two things: You are going to have a lot of superintendents, or else you are going to have only a few great, big contractors. In pioneer work sometimes a lot of money has been made. I have seen that in offering work and asking for proposals a number would look it over and make their bids, but some fellow would know the conditions better than the other, and know how to save a lot of money and time by knowledge of those facts. However, he would go in and make a good big bid, and the owner would accept it, and the consequence be that he would make a lot of money.

There is, of course, the social side to consider. Will labor, as a rule, be better compensated or its welfare enhanced by either method? Personally, I do not think so, as welfare is a matter for legislation, and compensation must be determined either by the market or by legislation.

There is a growing disposition all over the country to eliminate competition, but it seems to me that the better results will be obtained only where competition produces waste, but not where it is a creator of new methods, inventions and energy.

FINANCING OF HIGHWAY IMPROVEMENTS*

Maintenance from Motor Fees—Direct Appropriations and Special Assessments—Bond Issues Becoming Popular

By J. E. Pennybacker
Secretary of The Asphalt Association; Formerly of the U. S. Bureau of Public Roads

THERE are eight distinct sources of road revenues. These are: (1) Personal taxes paid in labor and by an arbitrary annual fee, known as a poll tax; (2) direct property taxes; (3) proceeds of registration and license fees on motor vehicles; (4) direct appropriations from general treasuries; (5) special assessments on property in road improvement districts and against property abutting and contiguous to a designated road; (6) sale of bonds; (7) appropriation by the National government; (8) collection of tolls, and (9) miscellaneous sources, such as sales of lands, profits from state industries, taxes on corporations, sale of permits, etc.

It may appear from the foregoing that the public road reaches all of the possible sources of taxation, and, theoretically, this is true, but, practically, the general trend of road finance is toward a reliance upon direct property taxes, motor vehicles revenues, sale of bonds and Federal appropriations. The other sources are incidental and quite local in their application.

Statute Labor Sometimes Suitable

The labor tax has been ridiculed and condemned at every good roads meeting during the past decade. It is unquestionably an inefficient and wasteful method, both of paying taxes and building and repairing the road, but it is probably the lesser of evils in localities where a large proportion of the population holds little or no property, is thoroughly accustomed to manual labor as tenants of farms and plantations, and can only be reached effectively for the performance of civic duties through the imposition of a tax upon their manual rather than financial capacity. I should consider, therefore, that it might be desirable to consider the retention of some form of statute labor tax where the local conditions are such as I have described.

The direct property tax for road purposes probably will always be necessary, both as a source of revenue and as a means of reaching all beneficiaries of road improvement, but many reforms and improvements are necessary before this method of finance can be held to really serve its purpose equitably. It is well known that the ratio of taxable to actual value varies not only among the states and provinces in a wide degree, but in many of the states there is a wide variation among the several counties. Manifestly, if a state or provincial tax be levied for road purposes and

*Address before State Highway Officials.

the property in one county is assessed at 40 per cent. of its actual value, while the property in another county is assessed at 60 per cent. of its actual value, there is immediately an unjust discrimination against the latter county. The practice of equalizing assessments by boards of equalization should be vigorously urged in connection with the levying of taxes for road purposes.

Adjusting Direct Taxation Equitably

In some of the states, cities are not taxed for county purposes, and, consequently, heavy automobile traffic from cities exerts a destructive influence upon country highways without any corresponding return in the form of taxes. The remedy is either to make the cities taxable by counties for road purposes or to include practically all of the heavily-travelled highways in the state or provincial system and reach the cities by the direct state tax. It would seem to be fundamentally necessary that roads be classified and segregated into distinct systems as a condition precedent to the establishment of direct property taxes. Probably some budget plan could be worked out in which the requirements of the state, county and township highway systems respectively could be ascertained, and the total tax rate then adjusted so as to yield amounts proportionate to such findings. The net outcome would be that the man who lived on a state road would pay the heaviest tax, the man who lived on the county road the next heaviest, and the man who lived on the township road the lightest tax, but each, instead of paying three distinct taxes, would pay one.

For the reason that it is easier to convince the public of the necessity of building a good road than it is to convince them of the necessity of keeping it up, I would advocate dependence upon the direct property tax as far as possible for the construction of state or provincial roads and for meeting interest and retirement requirements on state bond issues, thus leaving to motor vehicle fees the burden of first supporting state highway organizations and maintaining the roads, and applying only the surplus from such revenues to the construction of roads and the payments of principal and interest of bonds. For county and township roads it will continue to be desirable and necessary to levy the direct property tax for practically all highway purposes, less such amounts as may be granted by the Federal government and the states or provinces as aid.

Motor Fees for Maintenance

Proceeds of motor vehicle registrations and licenses have increased enormously during the past few years.

As suggested in the preceding paragraph, this revenue should first be applied to the support of state highway departments and to the maintenance of state highways for the reason that the revenues are regularly available without the irritation to the taxpayer which comes from levying a direct tax each year. In other words, having secured a good road, the average taxpayer is apt to consider the road as a permanent institution, and to resent the necessity of continuing to tax himself to keep it up, whereas, he is not so likely to oppose spending the generous motor vehicle revenues for this purpose. I believe, therefore, that it is a mistaken zeal which seeks to tie up motor vehicle revenues for the payment of interest and retirement of bond issues, thus leaving to the tender mercies of the taxpayer the roads built at great expense and for which debt has been incurred.

Questions as to the basis of levying the fees on motor vehicles are interwoven in a very intricate manner with questions of regulation looking to the protection of the highway, so that the matter is not purely one of revenue. Thus far the tendency seems to be quite general to base the tax on the ordinary motor vehicle on horse-power at rates now generally regarded as equitable at anywhere between 40 cents and $1 per horse-power. Motor trucks, on the other hand, are more generally taxed on a weight basis. It would seem that there has been too much of a tendency on the part of each state to follow precedent. There ought to be good possibilities for the working out of an efficient and equitable basis of motor vehicle taxation through joint action of the best-informed men in those state highway departments which have had most intimate contact with this problem. The findings of such a committee would be exceptionally helpful to all of the states.

Appropriations and Special Assessments

Direct appropriations from general revenues are practicable in large and wealthy states or provinces and municipalities, but in view of the urgent necessity of carrying on highway construction and maintenance according to a comprehensive system and over a period of years, the dependence upon annual appropriations is too precarious to permit dependence upon this plan except for special and temporary purposes.

Special assessments in road improvement districts is a method of finance sometimes followed, and practically means the formation of a corporation of landowners who voluntarily bring upon themselves taxation for the purpose of improving their property by means of better highways. This method has proven successful in obtaining improved roads which could probably not be obtained through dependence upon popular vote. It localizes the burden, however, and is not equitable unless the road is of purely local importance. Any road used by traffic outside of the improvement district should have a wider field of taxation.

Bond issues for highway improvement are becoming popular at a rate which is not altogether reassuring. Certain fundamental questions, such as the length of term of the bonds, their payment on a serial rather than a sinking fund basis, the rate of interest, the determination of the roads to be improved, the solving of the difficult problems of type and dimensions of roads, should be worked out ahead of the sale of bonds so that these vast outlays may not produce such niggardly results as to cause a reaction.

Toll System Has Application

The collection of tolls, while generally tabooed by intelligent public sentiment, may yet assume a position of real importance in the financing of road work. In the old days objection was made to tolls because they were usually collected by private companies on public rights-of-way, because the cost of collection was out of all proportion to the amount of revenue derived, and because it was impossible to prevent gross dishonesty. It is possible to meet these faults by having the toll collected by the state or province and not by private companies. Traffic has become so enormous as compared with the old days, and automatic devices for collecting and recording collections have been so highly developed as to make it possible to collect tolls at the cost of a small percentage of the total collections. The destruction to the roads of one tax jurisdiction by traffic coming from other tax jurisdictions naturally directs attention to the toll system as one means of meeting this condition. The toll system is distasteful and inconvenient to the road user, and may be made unduly expensive, but on the general theory that payment should be made for service rendered, it would hardly seem that the road user could legitimately object to paying for the benefit of using a good road. I am not prepared to advocate the toll system, but I consider that it should not be dismissed lightly as a relic of the barbarous ages.

Restriction of Federal Aid

Finally, the aid granted by the Federal government has become of considerable magnitude. At present it is left to the state highway departments in the first instance to determine where the Federal aid is to be expended. It would certainly seem that the national government should concern itself with those roads which are of national importance, and, in line with this conclusion, the granting of Federal aid should be restricted to a national system, or at least to those roads which are interstate in character. If this be done, it will be one more step in the logical development of the principle of apportioning burdens to each unit of government according to the benefits derived.

WORLD'S MOST POWERFUL PRIME MOVER

WHEN reading the heading, "The World's Most Powerful Prime Mover," which appears upon another page of this issue, the reader must bear in mind that the unit described is of the cross-compound type, and not a single generator and single turbine.

From an operating standpoint, however, this type of unit is as much a single unit as if but one generator were employed. All the steam passes through a single high pressure cylinder and the entire unit is controlled by one main throttle. The generators are started up and operated electrically as a single unit. Regardless of these facts, however, it is questioned by many engineers whether it is entirely proper to refer to a unit of this character as a "unit" unless the term be distinctly qualified in every case by the word "compound."

As a single unit, of course, no one of the three generators in the Interborough's 60,000 k.w. compound unit would compare in output with any one of a considerable number of other generators that have been built: For example, the 50,000 k.v.a., 187 r.p.m., vertical, water-turbine-driven generators that are being built by the Westinghouse Co. for the Hydro-Electric Power Commission's proposed Queenston plant; the 50,000 k.v.a., steam-turbine-driven unit which was installed about a year ago by the General Electric Co. in the plant of the Detroit Edison Co.; the 40,000 k.v.a. generator now under construction by the Westinghouse Co. for a United States Navy battle cruiser, to be steam-turbine-driven at 1,500 r.p.m.; the 38,889 k.v.a., steam-turbine-driven generator installed by the General Electric Co. in the plant of the Buffalo General Electric Co.; the 35,000 k.v.a., steam-turbine-driven generator operated by the Commonwealth Edison Co., of Chicago; or the 32,500 k.w., water-turbine-driven generator (at 80% power factor) which has been built by the General Electric Co. for the Cliff Electrical Distributing Co., of Niagara Falls, N.Y., but which has not yet been installed.

Although the generators which are in the Interborough Rapid Transit Co.'s plant are not of extraordinary size compared to those above mentioned, these cross-compound units are remarkable in their output, and from an operating standpoint can really be called "units," so that the title of "World's Most Powerful Prime Mover" is no doubt fully justified.

Among the other large cross-compound units that have been installed recently or are now under construction, is a 60,000 k.v.a. unit, with three cylinders and three generators, for the United States Navy's nitrate plant at Muscele Shoals, Ala.; also a 47,000 k.v.a. unit, with two cylinders and two generators, for the Duquesne Light Co., of Pittsburgh, Pa. A unit similar to the Duquesne one has been built for the Narragansett Electric Light Co., of Providence, R.I., and one similar to the Muscele Shoals unit is now under construction for the Duquesne Light Co.

LAYING WATER MAINS IN ALLEYS

ALTHOUGH the plan of laying water, gas and steam mains, sewers, telephone conduits and other public services in alleys instead of in streets, has been frequently advocated and sometimes tried, Chas. R. Henderson, manager of the Davenport Water Co., of Davenport, Iowa, writing editorially in the journal of the American Water Works Association, contends that for reasons applying to safety and economy, water mains had best be laid in the streets, although he is willing to concede that the alleys can be utilized for some utilities.

The principal objection to the alleys in cities is that they are not wide enough to accommodate all of the underground work, and, as usually laid out, are not continuous, nor do they run in both directions.

A few years ago Mr. Henderson tried to lay a small water main in an alley because it was desirable to avoid cutting a new pavement. In this alley there were several conduits, used by telephone, telegraph and power companies, and at the entrance of the alley were three manholes of considerable size. The pipe could not be laid between the manholes because they overlapped; it could not be laid through them because the companies owning them objected; it could not be laid under them because the ground was solid rock and blasting would disturb the conduit system. As a result, the new pavement was cut and the pipe was laid in the street.

In an Iowa city the principal main in the commercial district was laid in alleys. Fire hydrants at street intersections are supplied by long branches of smaller pipe. These long hydrant branches add to the loss of head between the main and the hydrant, and, as there is no flow in the pipe between the main and the hydrant, the danger of freezing is greater than in a normal installation.

Shut-off cocks and curb boxes for outside control are best located on sidewalks, says Mr. Henderson, if they are to be accessible when needed. They should always be located on public property. When in alleys, heavy vehicles are likely to pass over and break them. Moreover, it is desirable to place curb boxes in such positions that they will not be covered by ash barrels, manure heaps or any other hindrances to their accessibility.

Mr. Henderson tried the laying of water mains in alleys in a new residential suburb at Davenport, with unfortunate results. The growth of the suburb necessitated the construction of mains in some streets, so now he has some parallel mains one-half block apart.

For the above-mentioned reasons, and on account of the difficulty of providing sufficient hydrants for proper fire protection when mains are in alleys, Mr. Henderson is firmly in favor of keeping all water mains in the streets, regardless of the effect upon pavement construction.

CANADA'S DEPENDENCE ON ELECTRIC POWER

Many Resources Can be Developed Only Through Use of Hydro-Electric Energy

FEW realize the important relation which Canada's wealth in water power bears towards reaping the full benefit from her numerous other natural resources. It is true that these other resources would not otherwise be entirely lost to the country, but they would have to be exported as raw material in its most primary state with a minimum return to us. The presence of cheap power, which is almost invariably found side by side with these other resources, facilitates their development, while their full industrial value is retained in being able to deliver them as a fully manufactured product.

It may be even permitted to predict that this cheap power will soon attract raw material from other countries. For instance, the large aluminium plant on the United States side of Niagara Falls is operating largely from hydro-electric energy exported from Canada. Had it been physically or economically impossible to export this energy, as the question of power is of utmost importance, these works would have doubtless been attracted to use it on the Canadian side.

In Canada, the pulp and paper industry has been greatly expanded through the proximity of abundant water power to our forest resources. A recent census bulletin on this industry shows that there is a total of 524,252 h.p. installed to operate pulp and paper mills in Canada. From other figures given it is fair to estimate that at least 475,000 h.p. of this is derived directly or indirectly from water power.

If we consider pulp mills alone, the figures from the bulletin also demonstrate the important part which power holds in connection with this industry. The Canadian mills producing pulp exclusively are stated to have a yearly output of 490,615 tons, for which it is necessary to use 95,463 h.p. In other words, one horse-power will produce approximately five tons of pulp yearly. This one horse-power usually costs from $8 to $10 with water power, while, if other sources of energy had to be used, the corresponding cost might be from $30 to $50. This would mean an increase in cost of at least $4 per ton, or, in all probability, if the water power had not been available, the pulp would not have been manufactured.—From "Conservation."

COMPULSORY TOWN PLANNING

TOWN planning in Great Britain has so far advanced beyond the experimental stage that it has now been decided to make it compulsory for every town. having 20,000 inhabitants or more, to submit a town planning scheme for its own area to the Local Government Board, not later than 1926. Such a scheme must embrace the limitation of population densities per acre, define the portion of a site area to be covered with buildings, the character of the buildings, the lines of arterial roads and the provision of open spaces.

The British people realize that haphazard growth of towns leads to serious evils and they are determined to control it. In future, land will have to be developed so as best to serve the interests of the community, which, in the long run, is usually in the interests of the landholders themselves. Only the land speculator is adversely affected. If the public wish to put that individual out of business, they cannot do it more effectively than by actively promoting proper schemes of town planning.

In Canada, the province of Nova Scotia took the lead in making town planning compulsory in 1915. The only other province which has a compulsory Act is Saskatchewan. These are therefore the only two provinces abreast of the Old Country in town-planning progress, though most of our provinces have enabling Acts in force.—From "Conservation," published by the Commission of Conservation, Ottawa.

PERSONALS

JOHN LEY RETALLACK, of Vancouver, B. C., who was recently appointed as the first public utilities commissioner for the Province of British Columbia, has had experience in railway construction, banking, mining and corporation accounting. He served for five years with the Royal Northwest Mounted Police, and after his discharge in 1889, settled in the Kootenay district of British Columbia. At the outbreak of war he obtained a commission and soon became a major. He was at Ypres and the Somme and subsequently was connected with railway construction work at the Front. R. H. Gale, mayor of Vancouver, was first appointed to the position by the provincial government, but the Great War Veterans' Association protested against the appointment, urging that Major Retallack should receive the post on account of his war services and because of his technical qualifications. On account of this protest, Mayor Gale resigned two or three days after he had been appointed, and the provincial government then named Major Retallack. He is now examining into the scope and methods of public utility commissions elsewhere. His headquarters will be at Vancouver.

ALFRED G. KING, JR., formerly of the firm of King, Evans & Pickard, of Victoria, B.C., has been appointed city engineer of Nanaimo, B.C.

A. R. ROBERTS, formerly of Burns & Roberts, Ltd., has opened an office at 201 Bank of Hamilton Bldg., Toronto, and will deal in new and used machinery, contractors', railway and power plant equipment.

T. CARMICHAEL, who was assistant superintendent of the Public Works Department, Regina, Sask., is now directing the department in place of W. T. Mollard, formerly superintendent, who recently resigned.

L. P. BURNS, president of Burns & Roberts, Ltd., Toronto, has bought the interest in the firm held by A. R. Roberts, and will continue the business as formerly, the organization otherwise remaining unchanged.

MAJOR A. G. NUTTER, who prior to going overseas was connected with Mussens Limited, has associated himself with the exporting and importing firm of Wonham, Bates & Goode, Inc., New York and London. This firm has just opened an office at 145 St. James St., Montreal, under the management of Major Nutter.

GEORGE A. JOHNSON, whose partnership with Major W. L. Benham was announced in this column a short time ago, was promoted July 3rd to the rank of colonel. Colonel Johnson entered the service in the spring of 1918, as major, and was promoted to lieutenant-colonel on November 7th, 1918. He is now second in command of the operation and repair branch of the construction division of the U.S. Army, in charge of the operation and maintenance of road, railroad, building, water supply, sewerage, electrical and all other utilities in the various establishments under the jurisdiction of the United States War Department.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

BRIDGES, ROADS AND STREETS

Arnprior, Ont.—The following contracts have been awarded by the county council: Berlanquet's bridge, on Road No. 15, Admaston and pipe culvert on that road by day labor; Jamieson's culvert over creek at $195.75 and culvert over Streasman's Creek for $4,748.50 to Grant Bros.; arch culvert over Hennessy's Creek to J. M. Kennedy at $7,865.75; concrete abutments on Road No. 5 at Beachburg to F. E. Fortin at $10,850.

Arnprior, Ont.—Three machinery units have been purchased by the county council. Roadwork will commence simultaneously at Pembroke, Renfrew and Arnprior. Cost of machinery, $5,614.83. Estimated cost of roadwork, $12,036.38.

Aurora, Ont.—Tenders will be received until noon, July 18th, for a bituminous bound macadam on concrete base pavement. (Official advertisement in this issue.)

Bancroft, Ont.—Hastings county council has authorized $30,000 to be spent on the provincial county highway, from Madoc to Tudor boundary north, and $25,000 from the boundary south. The county assumed as a county road a piece of highway about a mile in length running through Deloro.

Belleville, Ont.—Sidewalks will be constructed by the city council at a cost of about $16,635.06. J. W. Holmes, clerk.

Belleville, Ont.—The city council plans to construct pavements on several streets. Estimated cost, $17,756.50. J. W. Holmes, clerk.

Bowness, Alta.—The Bowness motor road will be repaired this summer. Commissioner Graves.

Bridgeburg, Ont.—The town council is planning an expenditure of $10,000 for roadway improvements. Part of this will be spent on Jarvis St., which will be graded, and a considerable portion on the extension of the sewerage system through a certain portion of Amigari. Grading will also be done on Central Ave. Reeve Atwood.

Chatham, Ont.—The city council contemplates the purchase of an asphalt paving plant at about $20,000, to be used this summer in repairing streets.

Chatham, Ont.—Contract for pavements on Amelia St. has been given to George Field, Chatham.

Rejected tenders: From National Contracting Co, Henrietta St., $2,458; Rogers Rd., $1,828; Humewood Dr., $738; Westmount and Miller, $1,788; Mould St., $1,388. From Frank Angatto, Northcliffe and Miller, $2,870; Conway St., $660; Mould St., $1,275; Wellwood Ave., $1,188. From Grant Contracting Co., for Henrietta St., $2,200; Rogers Rd., $2,060; Glenholme Ave., $1,009; Westmount and Miller, $1,980; Northcliffe and Miller, $3,190; Wellwood St., $1,245. From Johnson, for Holborne St., $600. Tenders for McRoberts St., from Frank Angatto, $3,500; from Grant Contracting Co., $4,410; and from Johnson, $4,800, have been laid over for further consideration. Frank Barber, county engineer.

PARLIAMENT BUILDING, OTTAWA

TENDERS WANTED FOR
"GRANITE STEPS, CURBS, FLAGGING," ETC.

Sealed tenders will be received by the undersigned until **noon, July 21st, 1919,** for the "Granite Steps, Curbs, Flagging," etc., required in the construction of the above building.

All tenders to be based on the manufacture, supply and delivery at the building of the "Granite Steps, Curbs, Flagging," etc., shown and described by the plans and specifications.

The work of this contract shall be proceeded with immediately upon the signing of the same, and continued as may be directed and in such a manner as to ensure completion of the whole work by **October 31st, 1919.**

Plans, specifications and any other information required can be obtained at the office of the General Contractors, **P. Lyall & Sons Construction Company, Limited, Ottawa.**

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Minister of Public Works, for a sum not less than five per cent. (5%) of the amount of the tender, which will be forfeited if the parties tendering decline to enter into a contract when called upon to do so. If the tender is not accepted, the cheque will be returned. If the tender is accepted an additional cheque for a sum equivalent to five per cent. (5%) of the tender must be deposited before the contract is signed. The total security will be forfeited if the contractor fails to complete the work contracted for.

Payment for material will be made monthly.

The lowest or any tender not necessarily accepted.

Envelopes containing tenders to be marked, "Tender for Granite Steps, Curbs, Flagging, Etc.", and addressed to the undersigned.

JOHN A. PEARSON, Architect.
J. O. MARCHAND, Associate.
Centre Block, Parliament Hill,
Ottawa. 292

Barrett Specification Roof on the Geo. Pattinson Co. buildings, Preston, Ont. General Contractors—P. H. Secord & Sons, Brantford, Ont. Roofer—Brown Jarvis Roofing Co., Brantford, Ont. Architect—J. Micklen, Preston, Ont.

These Buildings all have Roofs that can be *forgotten* for 20 Years!

THE owner of each of these buildings has received from us a Surety Bond, issued by one of the largest surety companies in the world, *guaranteeing their roofs against leaks, wear, and maintenance cost for twenty years.*

Of course, Barrett Specification Roofs do not need this guaranty to make them wear and last. The fact that most of the important buildings in Canada have the Barrett Specification type of roof proves that.

Barrett Specification Roof on the plant of the Pollock Manufacturing Co., Limited, Kitchener, Ont. Architect—C. Cowan. Roofer—Brown Jarvis Roofing Co., Brantford Ont.

Barrett Specification Roof on Athelma Apartments, Toronto, Ont. Roofer—Reggin & Spence, Toronto.

We issue this Surety Bond Guaranty merely as a means of impressing upon you our confidence in Barrett Specification Roofs. The guaranty is your assurance that you have on your building a roof that will need no attention and will give you complete, unqualified satisfaction for twenty years at least, *and probably much longer.* All you need to do to have such a roof is to incorporate in your building specification this sentence: "The roof shall be laid according to The Barrett Specification dated May 1, 1916, and the contractors shall obtain for us the Barrett 20-Year Guaranty Bond."

There is no charge for this Bond. It is obtainable on any roof of fifty squares or larger in towns of 25,000 or more, and in smaller places where our Inspection Service is available.

It will be issued to reputable roofing contractors, approved by us, who use the materials specified and who will agree to examination and approval by our inspectors. Barrett Specification Roofs cost less per year of service than any other kind; they take the base rate of fire insurance; in fact, any way you look at it, a Barrett Specification Roof is the best roofing made for permanent buildings.

A copy of the Barrett 20-Year Specification, with roofing diagrams, sent free on request.

The Barrett Company LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER
ST. JOHN, N.B. HALIFAX N.S. SYDNEY, N.S.

Sandwich, Ont.—Separate tenders will be received until 8 p.m., July 14th, by E. R. Plans, profiles and specifications can be seen and form of tender obtained at the office of the chief engineer, Winnipeg; district engineer, Saskatoon, and district engineer, Edmonton. H. A. Dixon, chief engineer, Canadian National Railways, Winnipeg, Man.

FACTORIES AND LARGE BUILDINGS

Barrie, Ont.—Bulk tenders have been received by the town council for remodelling west ward school from R. F. Garrett at $69,980 and from the Ball Planing Mill Co. at $66,719. Included in the latter is $10,979 for heating and ventilating systems to be put in by Moffatt and Parr. The contract has been awarded to The Ball Planing Mill Co.

Bedford, Que.—Tenders will be received until noon, July 15th by E. M. J. Lamoureux, secretary-treasurer, county council of Missisquoi, Bedford, Que., for repairs to county building.

Cobalt, Ont.—Arrangements have been made to install a mill at the Ontario-Kirkland mine. The plant will have a capacity for treating 100 tons daily.

Donnacona, Que.—Tenders will be received until July 20th, for the building of a 150-ton pulp and paper mill; also fully equipped power plant to develop 5,000 h.p. on Jacques Cartier River. Plans and specifications upon application to "Pulp and Paper," Room 40, Toronto Stock Exchange Building, Toronto.

Edmonton, Alta.—The department of public works, Edmonton, Alta., has awarded general contract for agricultural schools at Raymond, Youngstown and Gleichen, to Smith Bros. and Wilson, Lethbridge. Tender prices: Raymond, $47,400; Youngstown, $48,600; Gleichen, $48,000. Rejected tenders: For Raymond, C. C. Potter and Co., Medicine Hat, $58,032.90; Mildman and McKellar, Taber, $58,750. For Youngstown, Bennett and White Construction Co., Calgary, $48,000; Thomas, Jamieson, McKenzie, Ltd., Calgary, $49,750; C. C. Potter and Co., Medicine Hat, $57,932.90.

Edmonton, Alta.—Pheasey and Batson have been awarded the contract for addition to Parkdale school. Tender price, $15,311.

Edmonton, Alta.—Contract for eight portable frame schools has been awarded to J. A. Peters. Tender price, $1,659 each.

Edmonton, Alta.—The Massey-Harris Co. has taken out a building permit for warehouse. Estimated cost, $12,000. S. F. Toby has the contract.

Edmonton, Alta.—The J. I. Case Threshing Machine Co. will erect machinery warehouse on 93rd St. Contract has been let to W. C. McArthur.

Elmira, Ont.—Great West Felt Co. has awarded contract for the erection of a $25,000 factory, to W. Hallman, Galt.

Ford City, Ont.—The Westcott Contracting Co. have the contract for erection of plant for the Imperial Oil Co. Approximate cost, $100,000.

Goderich, Ont.—The Convertible Tractor Corporation, of St. Paul, Minn., contemplates the erection of a manufacturing plant.

Guelph, Ont.—The Y.W.C.A. contemplate erection of building. Estimated cost, $30,000.

Halifax, N.S.—Bulk tenders will be received until noon, July 14th, by S. P. Dumaresq, architect, 14 Prince St., Halifax, for the erection and completion of a proposed building for the Navy League of Canada, corner of South and Barrington Streets.

Hamilton, Ont.—Debentures will be issued to the amount of $33,000 for repairs to central school. H. H. Lazier, chairman, board of education.

Hope, B.C.—Tenders will be received until noon, July 15th, by A. E. Foreman, engineer, public works department, Victoria, B.C., for the erection and completion of a six-room building. Plans and specifications can be seen at the office of the provincial constable at Hope, of J. Mahoney, Esq., government agent, court house, Vancouver, and the department of public works, Victoria.

London, Ont.—John Hayman and Sons have been awarded the contract for erection of a new theatre for Allens' Theatres, Ltd.

London, Ont.—Philip Secord, of Brantford, has been awarded the contract for the new Loew's Theatre, to be erected on Queen's Ave.

London, Ont.—The C. S. Hyman Co., tanners, will erect new building on George St.

London, Ont.—The Holeproof Hosiery Co., Bathurst and Clarence Streets, has awarded contract for building to the Stone and Webster Contracting Co., Boston, Mass. The new building will cost about $300,000, and it is said that the American firm agreed to erect it at $50,000 less than any local contractor.

Melfort, Sask.—Plans have been prepared by J. H. Puntin, architect, for a new creamery and cold storage plant, to be constructed by the Saskatchewan Co-operative Creameries Co. Probable cost, $50,000.

Montreal, Que.—A new school will be erected on Morgan Boulevard by the Protestant school board. Estimated cost, $300,000.

Montreal, Que.—F. A. Groth, 6 Cuthbert St., has been awarded a contract for additions to shops for the Montreal Tramway Co. Tender price, $7,000.

Montreal, Que.—The Maple Leaf Theatre Co., St. Lawrence Blvd., contemplates alterations at a cost of about $40,000.

Oshawa, Ont.—Four-room addition will be erected to Mary St. school. Mr. Smith, chairman, board of education.

Ottawa, Ont.—Votes of parliament for new public buildings include $400,000 for a new public building at London, Ont.; $24,000 for the Montreal post office; $23,000 for a new public building at Oshawa; $28,000 for an addition to the public building at St. Catharines; $115,000 to complete postal station "A," Toronto; $25,000 for improvements to public building at Portage la Prarie, Man.; $20,000 for a new public building at Kamloops, B.C.; and $10,500 for improvements to postal station "A" at Winnipeg.

Port Arthur, Ont.—Contract for the Hill St. school has been awarded to Captains King and Jenkins, Port Arthur, Ont.

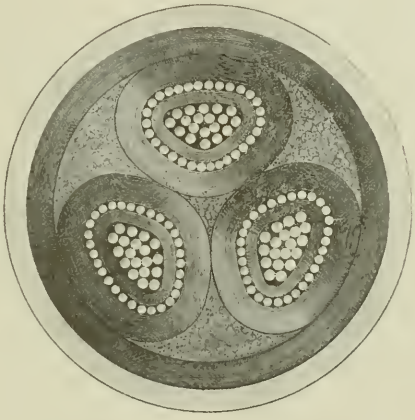
Regina, Sask.—Extensions will be made to R.N.W.M.P. barracks. New officers' quarters will be erected. Commissioner Perry.

Salt Springs, N.S.—The Canadian National Railways will erect station and freight shed.

Sarnia, Ont.—Tenders will be received until July 11th by James D. Stewart, city clerk, Sarnia, Ont., for the construction of a brick building and certain concrete work at the Point Edward water works. F. W. Thorold Co., Ltd., consulting engineers, 167 Avenue Road, Toronto.

Sault Ste. Marie, Ont.—Time for receiving tenders for court house has been extended to July 15th.

SPLIT-CONDUCTOR CABLES



250,000 C.M. 3-CONDUCTOR 13,200 VOLT
PAPER-INSULATED, LEAD COVERED CABLE

Eugene F. Phillips Electrical Works, Ltd.

MONTREAL

Branches: Toronto, Winnipeg, Regina, Calgary, Vancouver

Sherbrooke, Que.—G. Chauvin, 98 Darling St., Montreal, has been awarded the contract for a $50,000 factory for the Dominion Carriage Co., Ltd.

St. Hyacinthe, Que.—The Casavants Phonograph Co. plans extensive alterations and additions to factory.

St. John, N.B.—Tenders will be received by Henry Hedden, M.D., secretary of the board of commissioners, until noon, July 14th, for the construction of a nurses' residence at the general public hospital. Plans and specifications may be seen at the office of the architect, F. Neil Brodie, 42 Princess St.

St. Robert, Que.—Contract for school has been awarded to D. Ethier, St. Jude's, Que.

Vancouver, B.C.—The construction of an experimental plant as an adjunct to the University of British Columbia, is contemplated by the department of mines. Hon. Wm. Sloan, minister of mines, British Columbia.

Walkerville, Ont.—The American Auto Trimming Co. will erect addition to plant. Cost about $160,000. The Westcott Contracting Co. has been awarded the contract.

Weyburn, Sask.—Tenders will be received until July 26th, by R. W. Clarke, secretary, S.D. No. 512, Weyburn, Sask., for the erection of a school building. Plans may be secured from the secretary, or from Storey and Van Egmond, architects, Regina.

Winnipeg, Man.—Bulk and separate tenders will be received by E. D. Tuttle, architect, McArthur Bldg., Winnipeg, until noon, July 14th, for the rebuilding of the Makaroff consolidated school.

York Township, Ont.—Building permits for the month of June amounted to $425,000. Wm. Dever, township building inspector.

MISCELLANEOUS

Bare Point, Port Arthur, Ont.—The department of public works has awarded contract for construction of section of breakwater to Chambers, McQuigge and McCaffrey, Port Arthur. Under the name of the Nipigon Construction Co., the same people executed upwards of $7,000,000 work on the National Transcontinental Railway on the section north of Nipigon Lake.

Berthier, Que.—Tenders will be received until noon, July 24th, by R. C. Desrochers, secretary, department of public works, for repairs to wharf.

Burlington, Ont.—Contract for repairs to south pier has been awarded by the department of public works to Ottawa Contractors, Ltd., Ottawa.

Calgary, Alta.—Contract for stream diversions at mile 324 and 332, Calgary sub-division, has been awarded by Canadian National Railways to Carter, Halls, Aldinger Co., Ltd., Winnipeg. It is estimated that the diversion at mile 324 contains 60,000 yards, and mile 332, 17,000 yards.

Cornwall, Ont.—Tenders will be received until noon, July 22nd, by R. C. Desrochers, secretary, department of public works, Ottawa, for the construction of a wharf. Plans and forms of contract can be seen and specification and forms of tender obtained at the department of public works, at the office of the district engineer, Shaughnessy Building, Montreal, Que., and at the post office, Cornwall, Ont.

Edmonton, Alta.—Contracts will be awarded this week for the construction of about 400 miles of telephone lines in different parts of the province. Tenders for this work were called by the railway and telephone department a few weeks ago, and a large number of contractors have submitted tenders. Among the number will be lines from Pembina to Fort Assiniboine, in the north country; Edmonton to Clyde; Coronation to Veteran; Castor to Garden Plains; Medicine Hat to Hilda, and Retlaw to River Bow. The cost of the entire program is estimated at about $60,000.

Esquimalt, B.C.—The Federal government will expend $500,000 this year for construction of drydock. The total cost is estimated at about $4,000,000. Tenders will be called at once.

Fort William, Ont.—The Thunder Bay Contracting Co., of which Lieut.-Col. Little is manager, has been awarded the contract for driving the piles for the revetment wall.

Half Moon Bay, B.C.—Tenders will be received until noon, July 23rd, by R. C. Desrochers, secretary, department of public works, Ottawa, for the construction of a wharf in the Comox-Atlin District, B.C. Plans and forms of contract can be seen and specifications and forms of tender obtained at the department of public works, at the office of the district engineer, Victoria, B.C., and at the post offices, Vancouver, B.C., and Comox, B.C.

Nanaimo, B.C.—The Granby Consolidated Mining, Smelting and Power Co., Ltd., will construct wharf on Vancouver Island. F. M. Sylvester, managing director.

Nelson, B.C.—Extensive development work is to be carried out soon at the Whitewater and Comstock groups on Cascade Creek, in the Lardo district, and the Nonpareil group at Zincton. The properties belong to the Nelson Mining and Development Co., Spokane. W. W. Shaffner, general manager.

North Arm, B.C.—Tenders will be received until noon, July 30th, by R. C. Desrochers, secretary, department of public works, Ottawa, for dredging at North Arm, Fraser River, B.C. Combined specification and form of tender can be obtained on application to the secretary, department of public works, Ottawa, and at the office of the district engineer, New Westminster, B.C.

Ottawa, Ont.—Harbor and river votes by parliament include the following items: Esquimalt, new dry dock, $500,000; Port Arthur and Fort William, harbor improvements, $200,000; to complete Champlain dry dock, Quebec, $207,000; River St. Charles, improvements, Quebec, $55,800; St. John harbor improvements, $250,000; Toronto harbor improvements, $200,000; Toronto breakwater protection, $200,000; Vancouver harbor improvements, $18,000; Victoria harbor improvements, $21,000; $100,000 for a wharf at Sydney, N.S.; $82,000 to complete protection works at Laprairie, Que.; $50,000 for breakwater reconstruction at Collingwood, $34,000 for wharf renewal at Depot Harbor; $100,000 for harbor improvements at Hamilton; $54,000 for rebuilding wharf at Little Current; $33,000 harbor improvements, Port Stanley; $86,000 wharf construction, Owen Sound; $50,000 harbor improvements, Port Dover; $48,000 breakwater extension at Thessalon; western votes include $50,000 for dredging the North Arm of the Fraser River and $36,000 for improvements at Nicomen Island.

Ottawa, Ont.—$10,000,000 has been voted by parliament for construction of vessels.

Port Colborne, Ont.—Contract has been awarded by department of public works, for repairs to breakwater, to J. M. Hogan, Port Colborne.

Port Essington, B.C.—Tenders will be received until noon, July 31st, by R. C. Desrochers, secretary, department of public works, for float and approach.

St. Anne de Beaupre, Que.—Tenders will be received until noon, July 23rd, by R. C. Desrochers, secretary, department of public works, Ottawa, for repairs and reconstruction of wharf. Plans and forms of contract can be seen and specifications and forms of tender obtained at the department of public works, at the offices of the district engineers, post office, Quebec, P.Q., Shaughnessy Building, Montreal, P.Q., and at the post office, Ste. Anne de Beaupre, P.Q.

Toronto, Ont.—Plans are being prepared by city architect Pearse for livestock arena to be erected at the exhibition grounds.

Toronto, Ont.—The board of control has recommended the completion this year of the western water front improvements and the extension of the exhibition sea wall. Estimated cost, $487,000.

Toronto, Ont.—$200,000 has been voted by the government in the supplementary estimates for harbor improvements, and will be devoted to carrying on the work already in progress, particularly in the Sunnyside area. Further crib work in front of the exhibition grounds and in the western section and Ashbridge's Bay will also be done.

The Canadian Engineer

A Weekly Paper for Civil Engineers and Contractors

Convenient Method of Calculating Trash Racks

Table and Formulae by Means of Which Designers Can Readily Determine Lengths of Panels Between Supports for Various Spacings and Sizes of Bars—Structural Details and General Suggestions Regarding the Design of Racks

By E. BALBACH
Assistant Engineer, The James Leffel & Co.

IN calculating trash racks, we should assume that they may become completely clogged and will therefore be subject to the full hydrostatic pressure due to the head of water.

As this is the worst possible case that can occur, the structure will be safe if the stress in the bars for this condition is within the elastic limit of the material used, and we can therefore use a stress as high as 30,000 lbs. in our calculations. However, for the basis of these calculations we will assume a stress of 25,000 lbs. with full hydrostatic pressure imposed.

The pressure at any point will be directly proportional to its depth below the surface; i.e., the load on any bar will be represented by a triangle with the point or apex at the surface of the water.

For any given pitch or spacing of bars, then, the free span, or distance between supports for rack bars, is determined from the resisting moment of the bar used.

Using the notation given in Fig. No. 1, the length between the different supports can be determined as follows:—

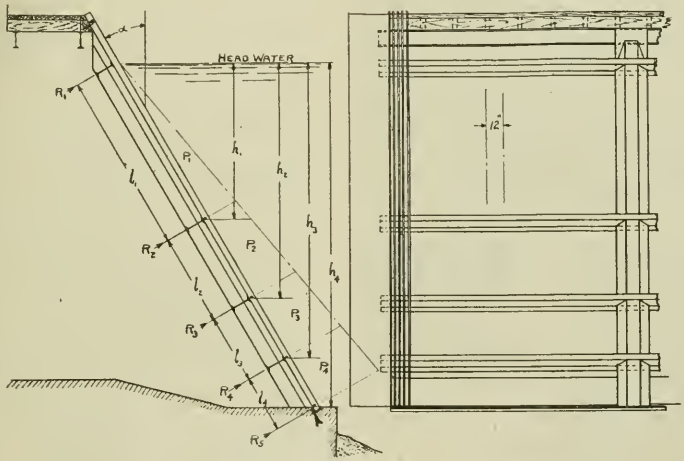


FIG. NO. 1—DIAGRAM INDICATING NOTATIONS IN FORMULAE

We will call these distances panel lengths and indicate them by l_1, l_2, l_3, l_4, etc., all in inches.

The loads P_1, P_2, etc., are for a width equal to the pitch of the bars. For the first panel, or l_1, the moment due to the load can be represented by

$$M_1 = 0.128 P_1 l_1 \quad \ldots\ldots (1)$$

where P_1 = total pressure on one bar;

l_1 = distance between supports in inches, considering ends free.

The resisting moment of the bar is

$$M_{r_1} = \tfrac{1}{6} b d^2 \times 25{,}000 \quad \ldots\ldots (2)$$

Where b = thickness of bar in inches;

d = depth of bar in inches; and the dangerous section will be at a distance

$$x = 0.5774 l_1 \quad \ldots\ldots (3)$$

from top support. The spacing bolts should be spaced to avoid this section, so as not to weaken the bar. The load

$$P_1 = 0.434 l_1 p h_1 / (12 \times 2).$$

Therefore,

$$P_1 = 0.0181 l_1^2 p \cos\alpha$$

where p = spacing of bars; $h = l_1 \cos\alpha$; and $\cos\alpha = \cos 30$ degs., generally 0.866.

By substituting for $\cos\alpha$,

$$P_1 = 0.0157 l_1^2 p \quad \ldots\ldots (4)$$

Substituting equation (4) in equation (1), we get

$$M_1 = 0.128 \times 0.0157 l_1^2 p = 0.00201 l_1^2 p \quad \ldots\ldots (5)$$

Equating (2) and (5), we get

$$0.00201 l_1^2 p = 25{,}000 bd^2/6 = 4{,}170 bd^2 \quad \ldots\ldots (6)$$

Now by assuming values at will for p, b and d, we have a cubic equation in l_1. By solving for l_1 we have the maximum allowable distance between supports for panel length No. 1. To carry the problem through we will assume a spacing of bars $p = 1\frac{1}{4}$ ins., centre to centre, and a bar ¼ in. by 2½ ins.

Substituting these values in equation (6), we get

$$0.00201 l_1^2 \times 1.25 = 4{,}170 \times 0.25 \times 2.5^3 \quad \ldots\ldots (7)$$

Therefore, $l_1^3 = (4{,}170 \times 0.25 \times 2.5^3) \div (0.00201 \times 1.25) = 2{,}590{,}000 \quad \ldots (8)$

Consequently, $l_1 = (2{,}590{,}000)^{1/3} = 135.5$ ins.

The perpendicular distance, or head, $h_1 = l_1 \cos\alpha = 135.5 \times 0.866 = 117.4$ ins.

Second Panel

Theoretically the second panel, or l_2, should be calculated as a continuous beam if the bars do not end at the lower support of the second panel, but, as frequently is the case, the total length of rack is divided into several panels and would therefore not be continuous, so we will again assume free ends. This assumption will in some cases give us a shorter length for l, but the discrepancy will be on the side of safety.

The load on the second panel will be represented by a trapezoid of which the shorter leg will be the same as the base of the upper triangle (for panel l) and the lower leg will be increased by the increment due to additional head. This loading can be subdivided into two loads, one a parallelogram with height equal to the short leg of the

trapezoid, and the other a triangle similar to that on first panel.

Let these loads be P_2 and P_2'. The moment will then be the sum of the two moments produced by these loads.

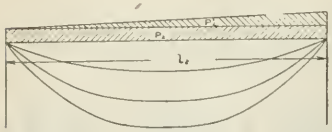

FIG. No. 2—LOADING ON No. 2 PANEL

Theoretically this is not correct because the maximum moment produced by each load does not occur at the same point. The maximum moment due to load P_2 occurs at the middle, while that due to load P_2' occurs $0.5774l_2$ from the upper support, or $0.0774l_2$ from the middle. Therefore the moment at the middle for load P_2' will be somewhat less, and the sum of the moments at the middle will be somewhat less, than that given in equation (9). For simplicity, however, we will assume the bending moment to be the sum of the two moments, as the difference is but small and the error gives us a safer result.

$$M_2 = \tfrac{1}{8}P_2l_2+0.128P_2'l_2 \quad \ldots\ldots (9)$$

in which

$$P_2 = 0.434h_1l_2p/12,$$

and

$$P_2' = \tfrac{1}{2}[(0.434h_1/12)+(0.434h_2/12)]l_2p$$

in which $h_2 = h_1+l_2\cos\alpha = 117.4+l_2\cos\alpha$.

Substituting the values of h_1 and h_2, we get

$$P_2 = \tfrac{1}{12}\times 0.434\times 117.4l_2p = 4.25l_2p \quad \ldots\ldots (10)$$

$$P_2' = [(\tfrac{1}{12}\times 0.434\times 117.4)+(\tfrac{1}{12}\times 0.434)(117.4+l_2\cos\alpha)]\tfrac{1}{2}l_2p$$
$$= [4.25+0.0362(117.4+l_2\cos\alpha)]\tfrac{1}{2}l_2p \quad \ldots\ldots (11)$$

The resisting moment as before is

$$M_{r_2} = 4{,}170bd^2 \quad \ldots\ldots (12)$$

Substituting the values of (10) and (11) in equation (9), we get

$$M_2 = (\tfrac{1}{8}\times 4.25l_2^2p)+(\tfrac{1}{2}\times 0.128l_2^2p)[4.25+0.0362(117.4+l_2\cos\alpha)]$$

Reducing and substituting for p and $\cos\alpha$, we get

$$M_2 = 0.664l_2^2+0.08l_2^2(4.25+4.25+0.0314l_2)$$
$$= 0.664l_2^2+0.68l_2^2+0.002515l_2^3$$
$$= 1.344l_2^2+0.002515l_2^3 \quad \ldots\ldots (13)$$

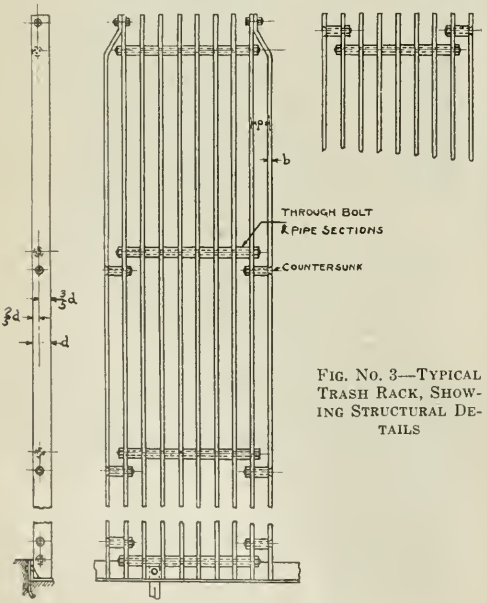

FIG. No. 3—TYPICAL TRASH RACK, SHOWING STRUCTURAL DETAILS

Equating (12) and (13), we get

$$1.344l_2^2+0.002515l_2^3 = 4{,}170bd^2 = 6{,}660 \quad \ldots\ldots (13a)$$

Solving for l_2 by trial, we get

$$l_2 = 67 \text{ ins.}$$

and

$$h_2 = h_1+l_2\cos\alpha$$
$$= 117.4+(67\times 0.866)$$
$$= 174 \text{ ins.}$$

Third Panel

The load on the third panel, or l_3, will be represented by a trapezoid, as in the second panel, with the short leg equal to the long leg of the trapezoid on second panel, and the long leg increased by the increment due to the additional head. This loading can likewise be divided into two loads, as in the case of the second panel.

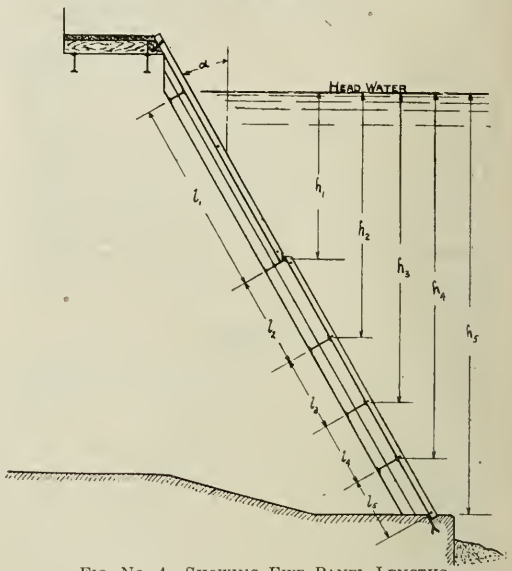

FIG. No. 4—SHOWING FIVE PANEL LENGTHS

Let these loads be P_3 and P_3'.

Then,

$$M_3 = \tfrac{1}{8}P_3l_3+0.128P_3'l_3 \quad \ldots\ldots (14)$$

in which

$$P_3 = \tfrac{1}{12}\times 0.434h_3l_3p$$

and

$$P_3' = \tfrac{1}{2}[(0.434h_3/12)+(0.434h_1/12)]l_3p$$

in which

$$h_3 = h_2+l_3\cos\alpha$$
$$= 174+l_3\cos\alpha$$

Substituting values for h_2 and h_3, we get

$$P_3 = \tfrac{1}{12}\times 0.434\times 174l_3p = 6.3l_3p \quad \ldots\ldots (15)$$

$$P_3' = [(\tfrac{1}{12}\times 0.434\times 174)+(\tfrac{1}{12}\times 0.434)(174+l_3\cos\alpha)]\tfrac{1}{2}l_3p$$
$$= [6.3+0.0362(174+l_3\cos\alpha)]\tfrac{1}{2}l_3p \quad \ldots\ldots (16)$$

The resisting moment, as before, is

$$M_{r_3} = 4{,}170bd^2 \quad \ldots\ldots (17)$$

Substituting values of (15) and (16) in equation (14), we get

$$M_3 = (\tfrac{1}{8}\times 6.3l_3^2p)+(\tfrac{1}{2}\times 0.128l_3^2p)(6.3+6.3+0.0314l_3)$$

Reducing and substituting for p, we get

$$M_3 = 0.985l_3^2+1.01l_3^2+0.002515l_3^3$$
$$= 1.995l_3^2+0.002515l_3^3 \quad \ldots\ldots (18)$$

Equating (17) and (18), we get

$$1.995l_3^2+0.00252l_3^3 = 4{,}170bd^2 = 6{,}660.$$

Solving for l_3 by trial, we get

$$l_3 = 56 \text{ ins.}$$

and

$$h_3 = h_2+l_3\cos\alpha$$
$$= 174+(56\times 0.866) = 288 \text{ ins.}$$

Fourth Panel

The load on the fourth panel, l_4, is similar to that on the second and third panels. Let these loads be P_4 and P_4'. Then

$$M_4 = \tfrac{1}{8}P_4l_4+0.128P_4'l_4 \quad \ldots\ldots\ldots\ldots\ldots\ldots (19)$$

in which

$$P_4 = \tfrac{1}{12}\times 0.434h_3l_4p$$

and

$$P_4' = \tfrac{1}{2}[(0.434h_3/12)+(0.434h_4/12)]l_4p$$

in which $h_4 = h_3+l_4\cos\alpha = 228+l_4\cos\alpha$.

Substituting the values of h_3 and h_4, we get

$$P_4 = \tfrac{1}{12}\times 0.434\times 228l_4p = 8.23l_4p \quad \ldots\ldots\ldots (20)$$

$$P_4' = \tfrac{1}{2}[(\tfrac{1}{12}\times 0.434\times 228)+(\tfrac{1}{12}\times 0.434)(228+l_4\cos\alpha)]l_4p$$
$$= \tfrac{1}{2}[8.23+0.0362(228+l_4\cos\alpha)]l_4p \quad \ldots\ldots\ldots (21)$$

The resisting moment, as before, is

$$M_4 = 4{,}170bd^2 \quad \ldots\ldots\ldots\ldots\ldots\ldots (22)$$

Substituting values of (20) and (21) in equation (19), we get

$$M_4 = (\tfrac{1}{8}\times 8.23l_4^2p)+(\tfrac{1}{2}\times 0.128l_4^2p)(8.23+8.23+0.0314l_4)$$

Reducing and substituting for p, we get

$$M_4 = 1.29l_4^2+1.317l_4^2+0.00252l_4^3$$
$$= 2.607l_4^2+0.00252l_4^3 \quad \ldots\ldots\ldots\ldots\ldots\ldots (23)$$

Equating (22) and (23). we get

$$2.607l_4^2+0.00252l_4^3 = 4{,}170bd^2 = 6{,}660.$$

Solving for l_4 by trial, we get

$$l_4 = 49 \text{ ins.}$$

and

$$h_4 = h_3+l_4\cos\alpha$$
$$= 228+(49\times 0.866) = 270.5 \text{ ins.}$$

In this way the length of panels between supports can be determined for any spacing of bars and any size bar. The accompaning Table No. 1, gives these lengths for bars ¼ in. by 2 ins. to ¼ in. by 4 ins. and spacing of 1¼ ins. to 3 ins. inclusive.

If it be desired to use a bar thicker than ¼ in., the length of first panel can be obtained from the table as follows:—

Cube the length, l, corresponding to a bar of the same height, d, and spacing p, and multiply by the width of bar to be used. Then divide by the width of bar in table (¼ in.). Extract the cube root of this result, and this will be the desired length, l_1. See equation (8).

By examining equation (13a), it will be seen that the second term of the left hand member is of small value, and the first term is the controlling factor, and we can therefore say that the length varies as the square root and not as the cube root, with no appreciable error. We can therefore say that the length of all panels after the first vary as the square root of the resisting moment of the bar. As this moment is directly proportional to the thickness of the bar, the values of l_2, l_3, etc., can likewise be taken from the table by squaring the length given in table for a bar of the same height and spacing, and multiplying this result by the desired thickness, and dividing by the thickness used in the table (¼ in.), then extracting the square root and using the values of l_2, l_3, etc., so obtained.

For example, say it is desired to use a bar ⅜ in. by 3½ ins. instead of ¼ in. by 3½ ins., and a spacing of 2 ins. Then l_1 from table = 147 ins. Let l_1' = the desired length for ⅜ in. by 3½ ins. bar. Then

$$l_1' = (l_1^3\times 0.375/0.25)^{1/3}$$
$$= l_1(0.375/0.25)^{1/3}$$
$$= 147\times 1.145 = 168 \text{ ins.}$$

Let l_2' = second panel length. From table, l_2 = 69 ins. Therefore

$$l_2' = (l_2^3 0.375/0.25)^{1/3}$$
$$= l_2(0.375/0.25)^{1/3}$$
$$= 69\times 1.225 = 84.5 \text{ ins.}$$

Let l_3' = third panel length. From table, l_3 = 57.5 ins. Therefore

$$l_3' = (l_3^3\times 0.375/0.25)^{1/3}$$
$$= l_3(0.375/0.25)^{1/3}$$
$$= 57.5\times 1.225 = 70 \text{ ins.}$$

Let l_4' = fourth panel length. From table, l_4 = 51.5 ins. Therefore

$$l_4' = (l_4^3\times 0.375/0.25)^{1/3}$$
$$= l_4(0.375/0.25)^{1/3}$$
$$= 51.5\times 1.225 = 63 \text{ ins.}$$

Of course this is only true when the angle of the rack bar is 30 degs. from the perpendicular. For any other angle, the panel lengths should be determined from the foregoing equations by substituting the proper value for $\cos\alpha$.

The values here given in Table 1 will be safe for the worst conditions imaginable, because the stress used is inside the elastic limit of steel. If the designer wishes to use a different stress, he need only multiply l_1, from the table, by the cube root of the quotient, stress (S) divided by 25,000; that is, multiply l_1, from the table, by $(S/25{,}000)^{1/3}$ for the first panel length, and by $(S/25{,}000)^{1/3}$ for l_2, l_3, etc.

TABLE 1

*$M = \frac{1}{6}\times bd^2\times 25{,}000$.

Construction of Panels

The bars are usually held together by through bolts, with sections of wrought-iron pipe of proper length strung between the bars, as shown in Fig. 3. The through bolt is placed back of the centre line of the bar so that the cleaning rake will not catch so readily.

The nuts on the bolts should not project outside the panel but should be guarded by a bar which is riveted at both ends. If this is done, the rack panels can be easily withdrawn and replaced.

The lower end of the rack bars can rest in an angle iron embedded in the concrete, and the upper end should be anchored by means of a hook engaging the spacing bars.

Supporting Structure

There are various methods for supporting the bars, depending on the construction of the adjacent building. If dividing walls can be placed at frequent intervals so as not to make too great a spacing, then I-beams can be embedded in these to support the racks. Such an arrangement is

shown in Figs. 1 and 3, where the walls stop behind the rack bars, so as not to obstruct the flow through the racks. The beams can then be determined from the conditions for uniform loading, and in Table 2 is given the loading per foot of length of beam. Where the spacing is too great for an economical beam, a steel truss can be placed midway between the walls.

TABLE 2—LOADS PER FOOT WIDTH OF RACKS

$R_1 = P_1/3$. $R_2 = 0.66P_1+0.47\ (P_2+P_2')$.
$R_3 = 0.53(P_2+P_2')+0.47(P_3+P_3')$.
$R_4 = 0.53(P_3+P_3')+0.47(P_4+P_4')$.
$R_5 = 0.53\ (P_4+P_4')$.

If the walls cannot be extended, then steel trusses will have to be built at intervals throughout the whole length of trash racks, and the beams supported on these.

In General

The effective area of the racks should be somewhat larger than the canal into which they lead, so as not to cause too great a loss in head.

The effective area will be the space between the bars multiplied by the perpendicular height. Allowance must also be made for obstruction by supporting beams and trusses.

The number of bars to make one panel is fixed by the the allowable weight and means for handling same when removing for cleaning, etc. Space the through bolts so that they come on a supporting beam and the bar will not be weakened.

Tenders will be received by the secretary of the Board of Control of Ottawa, Ont., until Tuesday, July 29th, for the supply of the following quantities of water meters: Fifty ⅝-in., twenty-five ¾-in., twenty-five 1-in., ten 1¼-in., fifteen 1½-in., seventy 2-in., thirty 3-in., ten 4-in., twelve 6-in. and four 8-in.

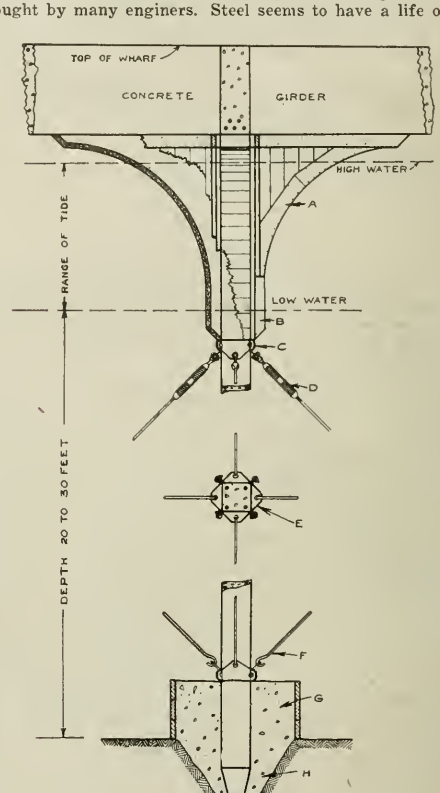
SUGGESTED STANDARD CONCRETE WHARF

By C. R. Coutlee
Department of Public Works, Ottawa, Ont.

THE accompanying drawing is an endeavor to create standard practice with regard to wharf construction in fresh and salt water, and any criticisms of the type shown will be appreciated.

With rock bottom, or with rock only slightly covered with earth, it seems possible to secure the bottom of pile as shown.

The matter of diagonal bracing has been given much thought by many enginers. Steel seems to have a life of 25 years or more if kept always below water level in fresh or sea water. Reinforced concrete also appears to be permanent when always immersed.



TYPICAL CONCRETE PILE WHARF CONSTRUCTION

A—Concrete deposited into and protected by grooved and tongued, creosoted forms, lined with Muntz metal, that remain as part of structure; B—Step-out to ensure that steel reinforcing rods are well covered from salt air; C—Adjustable steel band; D—Steel tie-rod to foot of next pile, with turnbuckle for adjustment; E—Detail of adjustable steel band placed after concrete pile is driven, to which tie-rods are attached; F—Steel tie-rod to top of next pile; G—Concrete deposited in wooden form by pipe from surface, or in bags; H—Rock blasted out to insert foot of concrete pile.

Above low tide, concrete is affected by clinging ice and by salt air. To protect it, grooved and tongued, creosoted covering is suggested. To prevent oil affecting the concrete, the creosoted covering should be lined with sheet copper or Muntz metal or else painted.

If the steel band to which diagonals are attached tends to slip upwards, it is suggested that a canvas bag partially filled with cement be slipped down the pile to rest upon and seat around the steel.

CANADA'S FUEL PROBLEM — SOME NATIONAL AND INTERNATIONAL ASPECTS*

By Arthur V. White
Consulting Engineer, Commission of Conservation

So much has been said, drawn from seemingly authoritative sources, respecting the "unbounded extent of the natural resources of Canada," that it is little wonder the popular view is entertained that Canada's resources are practically unlimited, and perpetual prosperity only waits upon their fuller development. For Canadians, however, to hold and be governed by such a view is to live in a "fool's paradise."

Little more than a decade ago, a large majority of the people of the United States believed that the natural resources of their country were unbounded, and that there was hardly any limit to material progress based upon their development. Even in that country, however, there were many who did not share these views, and through their efforts special investigation was made respecting the actual conditions of the natural resources of the nation.

Natural Resources are Exhaustible

No country possesses, within its own borders, more varied and extensive resources than the United States, yet it is now recognized that many of these are within measureable distance of exhaustion. This fact was so clearly demonstrated that prompt action by the trustees of the nation became imperative. So far as one can judge, natural resources from the 49th parallel to the Gulf of Mexico are better situated, geographically, and must always be more desirable than those from the 49th parallel to the Arctic ocean; thus, by reason of situation, Canada's usable natural resources are, in variety and extent, less than those of the United States.

Those who have observed the rapid disappearance of many of the natural resources of Canada and the present alarming rates at which some are being consumed, realize that the situation, as a whole, is one of great gravity. Consequently, true conservation in Canada is as great, if not a greater necessity than in the United States.

Must Use and Conserve

It is true that some resources, such as minerals—perhaps more especially coal, oil, and gas—if used, must in time, necessarily become exhausted. On the other hand, such resources as the soil, plant growth, waterways and ground waters, may be conserved and transmitted to posterity unimpaired, or at least unabused, just as a good husbandman passes on his farm in an improved condition to that in which he received it. The policies advocated by the Commission of Conservation of Canada have aimed at passing on to succeeding generations in an improved condition the heritage of the natural resources of this country.

By intelligent and thrifty use, the natural resources of Canada may beneficently serve the needs of a large population. If, however, Canadians become really dependent upon necessary commodities supplied them by other countries, they must be prepared to accept the circumstances in which they may suddenly find themselves if the supply of such commodities is cut off. Such circumstances will be aggravated by any abuse of our assets.

Coal Scarcity and Coercion

There is, apart from food, raiment and shelter, perhaps no single commodity which has been found so necessary as fuel—chiefly coal—for the maintenance of life and for the carrying on of commerce and transportation. Recently the public interest has been keenly aroused respecting the nation's fuel supply and increasing dependence upon hydro-electric energy. War conditions have driven home to Canadians as never before the tremendous gravity of their position with respect to fuel.

*From the General Electric Review.

Countries like Norway and Sweden, Denmark, Holland and Switzerland—countries, indeed, which were neutral—were practically dependent upon the warring nations for coal, and found themselves seriously curtailed in obtaining this commodity. They were forced to recognize the momentous fact that the countries which possess coal are able, absolutely, to dictate the terms upon which coal will be supplied to others.

Dependent Upon United States

Now, a very large portion of Canada—and for this one may hold in mind much of the populated territory extending, say, from Quebec to Winnipeg—has become increasingly dependent for its fuel supply upon the coal fields of the United States, and absolutely dependent upon that country for its annual supply of some 4,500,000 tons of anthracite.

In addition to the use of imported anthracite for heating and domestic purposes, large quantities of bituminous coal—some 10,000,000 to 14,000,000 tons—are also imported annually from the United States, largely for power purposes.

The known anthracite fields of the United States are within measurable distance of exhaustion. Doubtless, in the not distant future, the United States will feel compelled so to conserve this valuable commodity that the exportation of it may be largely restricted, if not entirely cut off. There are available many examples, arising out of the great European war conditions, where the United States has found it necessary to place stringent embargoes upon natural and manufactured products.

Now, if Canada is to be in a position to command special consideration under possible restricted trade conditions, she must realize the value of her own resources and have them strictly under national control in order that she may be enabled to deal on a basis of *quid pro quo*. When the commodities of commerce are exchanged there must, of course, be a substantial basis for barter. When Germany demanded gold from Switzerland she offered to exchange coal. Suppose that the United States, in the conduct of her commerce, concluded that it was in the general interest of her citizens only to *barter* coal for certain commodities which she specially required, what desirable commodities has Canada to barter?

Nothing is further from the thought of the writer than to suggest that it is or that it would become the arbitrary desire of the United States to deprive Canada of the coal which at present is so necessary to life in Canada. It is important, however, to take cognizance of the fact that a nation, pressed by the demands of its own people, may be compelled, under certain conditions, to deprive other nations —in part at least—of even the necessaries of life until the needs of its own citizens are met. No country can be expected to send out of its confines that which is essential to the very existence of its own people.

It is not the policy of Canada to embargo her exports. She must, however, conserve against the day of her own need such resources as are available for barter. It certainly is sound policy to insure that commodities of national importance should not be exported without an adequate *quid pro quo*.

Some portions of the United States are as badly in need of coal from Canada as portions of Canada are in need of coal from the United States. Between these two great countries there is an exchange of many natural and manufactured products, and the problems which from time to time arise in connection with such interchange can be satisfactorily solved and the whole situation reduced to a good working basis.

Canada's Water-Power Heritage

Other than the products of her agricultural lands, mines, and forests, there are certain resources in Canada of unique and special value. Canada has an especially rich heritage in her water-powers, including her equity in international waters. To a large extent these water powers are still under the control of the people. This control is being zealously guarded so that as the country develops and sites come into the sphere of active economic importance they may be developed and used in the general public interest. Men

far-sighted in the fields of industry and finance have foreseen the extent to which present and future generations will become increasingly dependent on power, whether it be steam or hydro-electric.

Any estimate for the water powers of Canada must be presented and considered with a due appreciation of its limitations. Table I. representatively sets forth the water-power situation in Canada. By no means may all the water powers be economically developed.

TABLE I.—WATER POWERS OF CANADA
(Tentative Schedule)

Province	Total Estimated 24-hour Low-water Horse Power	Developed Horse Power (a)
Prince Edward Island	3,000	500
Nova Scotia	150,000 (b)	30,000
New Brunswick	300,000 (b)	15,000
Quebec	6,000,000	900,000
Ontario	6,000,000	1,000,000
Manitoba	2,700,000	83,000
Saskatchewan	250,000	5,000
Alberta	450,000	33,000
British Columbia	3,000,000	300,000
Yukon	100,000 (c)	13,000
North West Territories (d)	.....	.....
Total for Canada	18,953,000	2,379,500

(a) This column presents aggregates of installed capacities.
(b) Special investigation now in progress.
(c) A rough estimate made for inclusion in this summary, probably low.
(d) No reliable data available.

Canada has been aggressive in the development and utilization of her water-powers, and no large communities are better supplied with hydro-electric power and light than are places like Montreal, Ottawa, Toronto, Hamilton, Winnipeg, Calgary, Vancouver and Victoria.

The most striking example of hydro-electric energy being developed and distributed on a large scale in order to afford a supply of cheap power and light for communities is found in the work of the Hydro-Electric Power Commission of Ontario.*

This Commission, co-operatively with over 200 Ontario municipalities, has upwards of 3,000 miles of transmission line, and serves over 120,000 customers. In fact, nearly half the population of Ontario is supplied with electricity through the agency of the Commission. The capital investment of the province in connection with these undertakings approximates $55,000,000, in addition to which the various municipalities co-operating with the commission have made an investment of some $20,000,000 in connection with their local distribution and operating systems. This extensive use of electrical energy results in the annual saving of several millions of tons of coal.

Niagara River Power Development

At Niagara Falls, great power development has already taken place. There the capacity of the large power plants in Canada may be stated as in Table II.

Allotted Water all Taken

The total diversion for both countries of 56,000 cubic feet of water per second from the Niagara River as provided by the Boundary Waters' Treaty has now been fully allotted, and before long will all be in actual use by plants on both sides of the river. Suggestions are continually being made to have the treaty revised, so as to permit of greater diversion. One recent proposal is that under a new treaty each country shall be permitted to divert 60,000 cubic feet of water per second, which corresponds to approximately 1,800,000 electrical horse-power, assuming 30 h.p. to be developed per cubic foot of water.

An Exporter of Electricity

About 125,000 h.p. of Niagara hydro-electric power is exported to the United States. Canada is exporting electrical energy from New Brunswick to the state of Maine, from Quebec to New York, from Ontario to New York and to Minnesota, and from British Columbia to Washington. The United States is importing from Canada about 200,000 h.p. years of electrical energy.* Many factors, of course, enter into the determination of the equivalent of this electrical power in terms of anthracite. Speaking in round figures, and taking cognizance of some of these special factors, the electrical power now imported by the United States would be the equivalent of not less than 3,000,000 tons of coal—and doubtless is a quantity substantially greater, even 6,000,000 tons or possibly more, the determination of the equivalent being dependent upon what in any set of circumstances are found to be the governing factors.† It will thus

TABLE II.—NIAGARA POWER PLANTS IN CANADA

Plant	Rated Capacity of Present Installation. Horse Power	Approximate Maximum Generating Capacity. Horse Power
Canadian Niagara Power Co.	112,500	100,000 (a)
Ontario Power Co. (controlled by the Hydro-Electric Power Commission of Ontario)	159,000	162,000 (b)
Electrical Development Co.	135,800	125,000 (c)
Ontario Power Co.'s new pipeline (installed by Hydro-Electric Power Commission), completed 1919	32,000	32,000 (d)
Present total development	439,300	419,000
Chippawa plant under construction by Hydro-Electric Power Commission of Ontario, ultimate development	300,000	300,000 (e)
Total development now provided for	739,000	719,000

(a) At times has generated about 103,000 h.p.
(b) At times has generated about 163,000 h.p.
(c) At times has generated 146,000 h.p., but it is claimed that the water used to generate this amount exceeds the quantity legally usable to generate the 125,000 h.p. specified in the contract.
(d) This pipeline has a nominal capacity to supply water for 50,000 h.p., but the balance of water in excess of that required for the two new 15,000 kv-a. generators is used to increase the efficiency of operation of the older portion of the plant.
(e) To operate under a head of 305 feet and to utilize the descent of the Lower River.

be perceived that, on a power basis, the coal equivalent of the electric energy exported to the United States approximates the quantity of anthracite imported by Canada from the United States.

This electrical energy is, of course, much more profitably employed for power than for heating purposes. In this connection it may briefly be commented, with respect to the restricted possibilities of electric heating, that for years past the author has been emphasizing the comparatively limited use which can be made of electric energy as a wholesale substitute for coal for heating—including the heating of buildings. The sooner it is realized that hydro-electric

*A brief but comprehensive historical survey of the evolution of the Hydro-Electric Power Commission of Ontario, by Arthur V. White, is given in the Commission of Conservation's report, "Water-Powers of Canada," Ottawa, pp. 35-56. For a valuable resume of activities of the Commission, consult, "Electric Power Generation in Ontario on Systems of Hydro-Electric Power Commission," by Arthur H. Hull, in "Proceedings of American Institute of Electrical Engineers," January 1st, 1919; also published in "The Canadian Engineer," issues of December 12th and 19th, 1918.

*For discussion of various aspects of problems respecting the exportation and use of electrical energy, consult the following articles by Arthur V. White: "Exportation of Electricity," which appeared in the "University Magazine," October, 1910, pages 460, et seq. Consult, also "Toronto World," March 18th, 1912; also "Exportation of Electricity—An International Problem; Relation of a Possible Coal Embargo by United States to a Curtailment or Stoppage of Canada's Electric Power," in "The Monetary Times Annual" of January 5th, 1917, pages 21 et seq; also "Coal Problem of Canada Demands National Action—A Solution of a Vital National and International Question" in "The Monetary Times Annual," January 4th, 1918, pages 25 et seq; also consult, "Barter Power for U. S. Coal," in "The Globe," Toronto, November 27th, 1917; and "Monetary Times," Toronto, January 18th, page 9, and February 22nd, 1918, page 26.

†Consult the Hydro-Electric Power Commission of Ontario Report on the "Rate of Coal Consumption in Various Electric Generating Stations and Industrial Establishments in Canada and the United States," by A. S. L. Barnes, Toronto, 1918.

energy can never as a heating agent be an adequate substitute for coal for the citizens of Canada, the sooner will action be concentrated upon sources from which real relief may be derived—there is no use entertaining hope towards a source from which no sufficient relief can come. At the annual meeting of the Commission of Conservation, in November, 1917, the author stated that: "The extent to which electric energy will be available for heating has been much overrated and, realizing the underlying physical limitations one cannot be enthusiastic respecting the extent to which it may be utilized." This statement being made at a time of serious hardship due to power and fuel shortage, attracted widespread attention.*

St. Lawrence River Water-Powers

Outside of the Niagara district the greatest amount of water-power of immediate economic importance is found along the St. Lawrence River. On a conservative basis, the low-water power of the international portion of the St. Lawrence River may be estimated at about 800,000 h.p., of which Canada is entitled to one half, or 400,000 h.p. The correspondingly estimated low-water power on the portion of the river which lies wholly within Canada, is about 1,400,000 h.p., thus making an estimated total for Canada of 1,800,000 low-water continuous h.p. Assuming the diversity load-factor of the present Niagara system of the Hydro-Electric Power Commission of Ontario, Canada's 1,800,000 h.p. on the St. Lawrence would take care of a power demand of some 2,400,000 h.p. The St. Lawrence River power sites are detailed in Table III.†

Coal Resources of Canada

Now, we have seen how great are the water-power resources of Canada, and these, it may be observed, are largely spread over the areas which have no natural coal resources. These areas now importing coal will no doubt be increasingly supplied from the Canadian mines. Considering the country as a whole, Canada in respect of quantity, quality, and accessibility for mining purposes, possesses coal deposits which compare favorably with those of the greatest coal mining countries of the world. Canada, as we have seen, can never depend upon her water powers as a sole source for heat. Consequently, the alternative open to her, and it is this to which special attention is directed, is to develop, and that as rapidly as possible, both her own fuel and power resources, and by co-ordination of transportation and other cognate agencies to provide for the distribution of fuel to all communities in the Dominion. In some respects it is more important to move coal and have it adequately stored and distributed throughout Canada than it is to move the grain out of the country.

TABLE III.—WATER-POWER ON THE ST. LAWRENCE RIVER (Tentative Schedule) (a)

Site	Head Available	Estimated Low-water 24-hr. h.p.	Average Estimated 24-hr. Low-water h.p.
Morrisburg-Rapide Plat	11-15	170,000-230,000	200,000
Long Sault rapid	30-40	500,000-650,000	575,000
Coteau rapid	15-17	230,000-260,000	250,000
Cedars rapid (b)	30-32	490,000-525,000	500,000
Split Rock and Cascades rapids	14-18	220,000-280,000	250,000
Lachine rapid	20-30	300,000-450,000	375,000
Total	....	1,910,000-2,395,000	2,150,000

(a) In this table, to have the estimates fairly representative of the possible quantities which might be expected under representative low-water flow conditions, some allowances have been made for efficiency and other factors.

(b) Under development for about one-third of the low-water flow of the river. Consideration would be given to the possibility of combining the Coteau, Cedars, Split Rock and Cascades; also of increasing the Lachine power.

TABLE IV.—ESTIMATED COAL RESOURCES OF CANADA (a)

Province	Area of Coal Lands Square Miles	Semi-Anthracite Million Tons	Bituminous Million Tons	Sub-Bituminous Million Tons	Lignite Million Tons
Nova Scotia	521		10,691		
N.B.	121		166		
Ontario ...	10				27.5
Manitoba	48				176
Sask.	13,406				65,793
Alberta ...	81,878	845.9	217,918(b)	932,053	29,095
B.C.	6,045		77,923(b)		5,715.5(c)
Yukon	2,840		275(b)		5,159 (c)
N.W.T. ..	300				5,280 (c)
Arctic Is. ..	6,000		6,600		
Total	111,169	845.9	313,573	932,053	111,246

(a) Consult "Coal Fields and Coal Resources of Canada," by Dr. D. B. Dowling, Geological Survey of Canada; also "Coal Situation in Canada," by W. J. Dick, in "Transactions of the Canadian Mining Institute," 1916.

(b) Includes some anthracite coal.

(c) Includes some sub-bituminous coal.

The coal fields of Canada may conveniently be divided into four main divisions:—

1. The bituminous coal fields of Nova Scotia and New Brunswick.
2. The lignites of Manitoba and Saskatchewan, and the lignites, sub-bituminous and anthracite coal fields of Alberta and the Eastern Rocky Mountain region.
3. The semi-anthracite and bituminous fields of Vancouver Island, Queen Charlotte Island, and the interior of British Columbia, and the lignites of Yukon.
4. The low-grade bituminous coal and lignites of the Arctic-Mackenzie basin.

The coal areas and estimated quantities for the different provinces are shown in Table IV. There should, of course, for practical consideration, be a substantial reduction made in these quantities, due to waste in mining operations.

Coal Production and Distribution

Canada annually produces 15,000,000 tons of coal. Her coal and coke production in 1916, 1917 and 1918 are given in Table V. Canada is making special efforts to increase the production of, and areas served by, her coal mines. This is evident from the figures in the table for the province of Alberta, the mines of which, in 1918, increased their production by over 1,200,000 tons. The falling off in production from the Nova Scotia mines is more apparent than real. It is believed that but for the fact that the British Admiralty required, for war purposes, vessels which ordinarily would have been used for transporting coal from the Nova Scotia mines, considerably larger amounts of this coal would have been marketed in territory west of Montreal. No doubt increased quantities of coal will be shipped westward into central Canada through the 14-ft. navigation afforded from the sea to the Great Lakes by the present canal system of Canada.

As a result of the efforts of the Fuel Administration in Canada, there have been assembled considerable data not before available relating to the Canadian coal trade. Some of these data have now been incorporated in a valuable report on the coal trade of Canada. Table VI. from this report summarizes the facts respecting the output, importation and consumption of coal in Canada.*

*For several years past attention has been drawn by Mr. White to the relatively limited use that can efficiently be made of electrical energy as a heating agent. On February 11th, 1918, when addressing the important Fuel Conference held by municipalities in Galt (see "Galt Reporter," Februry 12th, 1918), Mr. White again emphasized his contention that, as a general proposition, electrical energy is more serviceably employed for strictly power purposes, while fuel, such as coal, oil, etc., is more profitably employed for heating. At this meeting he set forth the underlying principles governing in this matter. See "Monetary Times," March 1st, 1918, page 18. Consult, also, "Annual Reports of Commission of Conservation," Ottawa; and article by Mr. White, "Electricity will not Replace Coal," in "Industrial Canada," Toronto, April, 1918.

†From "Power Possibilities on the St. Lawrence River," by Arthur V. White, Ottawa, 1918. See, also, by same author, "Long Sault Rapids, St. Lawrence River, an Enquiry Into the Constitutional and Other Aspects of the Project to Develop Power Therefrom." Commission of Conservation. 384 pp. Ottawa, 1913.

*Consult "Report of the Coal Trade of Canada for the Year Ended March 31st, 1918," issued by the Internal Trade Division, Dominion Bureau of Statistics. 8vo., xiv., 59 pp., Ottawa, 1919.

Canada is making serious effort towards the development on a large scale of her lignite and peat resources; also, towards the increased utilization of her coal fields in the east and in the west. The sum of $400,000 has been made available to the Honorary Advisory Council for Scientific and Industrial Research of the Dominion government for the erection of a carbonized lignite briquetting plant of 30,000 tons of briquettes per annum. Of this sum, $200,000 was voted by the Dominion government and $100,000 each by the provinces of Manitoba and Saskatchewan. Work incident to the construction of the plant is under way. The estimated cost of the briquettes per ton at the mine, including all fixed charges amounting to 20 per cent. on the capital, is $7.*

TABLE V.—COAL PRODUCTION AND DISTRIBUTION IN CANADA

Coal Production in Canada (a)

Province	1916 Short Tons	1917 Short Tons	1918 (b) Short Tons
Nova Scotia	6,912,140	6,327,091	5,852,802
New Brunswick	143,540	189,095	267,746
Saskatchewan	281,300	355,445	345,310
Alberta	4,559,054	4,736,368	5,941,864
British Columbia	2,584,061	2,433,888	2,568,591
Yukon	3,300	4,872	2,900
Total	14,483,395	14,046,759	14,979,213
Distribution of Coal Produced (c)			
Sold for consumption in Canada	10,701,530	10,469,468	11,210,628
Sold for export to U.S.A	1,451,075	1,301,881	1,351,179
Sold for export elsewhere	284,513	301,060	317,135
Total sales	12,437,118	12,072,409	12,878,942
Used by producers in making coke, steel, brick, etc.	804,814	690,573	682,304
Used by producers for colliery operations and by workmen	1,241,463	1,283,777	1,417,967
Total used by producers	2,046,277	1,974,350	2,100,271

(a) Consult "The Production of Coal and Coke in Canada," by John McLeish, B.A., Chief of the Division of Mineral Resources and Statistics, Department of Mines, Ottawa.
(b) Preliminary figures, subject to minor modification.
(c) This is merely a record of distribution by the companies operating the collieries. The figures "Used by producers making coke, steel, brick, etc.," do not represent the total amounts of coal used even in making coke by coke-oven operators.

Peat Resources of Canada

Respecting the peat bogs of Canada, Dr. Eugene Haanel, director of mines, Canada, has strongly urged the necessity of developing our peat resources, and at a recent annual meeting of the Commission of Conservation of Canada, he gave an able, forceful and serious address upon this subject which the people of Canada cannot too carefully consider. Dr. Haanel affirmed the commercial and economic practicability of peat production. Many persons who have had their interest and hope aroused in the prospects of commercial peat, feel that sufficient time has already been available for "experimenting" with peat. They feel that if essential conditions respecting the acquirement of bogs are rightly provided for, and the employment of the best processes of manufacture and handling, costs, etc., are known, the peat industry should by this time have become commercialized the same as other profitable industries. Throughout Canada there have already been discovered areas of peat bog estimated to aggregate 37,000 square miles. According to a broad estimate by Dr. Haanel, and assuming an average depth of bog of six feet, this area corresponds to over 28,000,000,000 tons of peat, having a fuel value equivalent to over 16,000,000,000 tons of good coal. Manitoba, Ontario, Quebec and New Brunswick have peat bog areas aggregating 12,000 square miles.*

The province of Ontario has recently created a Peat Commission, which, it is stated, has two experimental plants in process of construction.

Petroleum Resources in Canada

Canada is known to possess great areas of rich petroleum-bearing shales and sands. Although considerable work has been performed in such areas—as in New Brunswick—nevertheless, the industry cannot really be said to be commercialized. Having in mind the success of the oil shale industry in Scotland, there appears little doubt but the corresponding industry in New Brunswick, Nova Scotia and elsewhere, will ere long become extensive.

TABLE VI.—COAL OUTPUT, IMPORTATION AND CONSUMPTION OF COAL IN CANADA

	1915	1916	1917
West of Head of Great Lakes:			
Output B.C.	2,208,289	2,783,849	2,676,760
Output Alta., anthracite	125,732	140,544	118,717
Output Alta., bituminous	1,626,237	2,335,259	2,206,868
Output Alta., lignite	1,682,922	2,172,801	2,537,829
Output Sask., lignite	243,125	294,264	360,623
Imported from U.S.A., anthracite	298,895	533,846	514,688
Imported from U.S.A., bituminous	1,423,882	2,550,352	2,825,702
Total tonnage made available	7,609,082	10,810,915	11,241,187
Exported	864,160	1,105,718	1,029,532
Net consumption	6,744,922	9,705,197	10,211,655
East of Head of Great Lakes:			
Output Nova Scotia	7,513,739	6,911,995	6,345,335
Output New Brunswick	126,923	143,658	189,668
Imported from U.S.A., anthracite	3,773,135	4,040,368	4,805,000
Imported from U.S.A., bituminous	7,622,449	10,739,478	14,394,122
Total tonnage made available	19,036,246	21,835,499	25,734,125
Exported	902,383	1,029,641	703,824
Net consumption	18,133,863	20,805,858	25,030,501
Total consumption in Canada	24,878,785	30,511,055	35,242,156

According to all indications, the year 1919 will see the greatest prospecting propaganda for oil that has occurred in Canada. Many interests—Canadian, British and United States—are arranging for prospecting parties with modern equipment and oil experts to prospect, especially in Alberta and British Columbia.

Respecting the possibility that petroleum will be discovered, particularly in the Viking area and the Peace and Athabaska valleys, "the situation may be summed up as very promising," states Mr. James White in his recent monograph on the "Fuels of Western Canada."†

He states further:—

"A small quantity of dark oil obtained in one of the wells in the Viking gas field is an encouraging indication, and oil has also been found in the Pelican Rapids gas well. Seepages of oil have been found near Waterton Lake, in

POINTS REQUIRING SPECIAL OBSERVATION AND INVESTIGATION IN BRIDGE INSPECTION*

By Herbert C. Keith

THE old proverb that a chain is no stronger than its weakest link seems sometimes to be contradicted by a bridge truss, which may be stronger than its weakest member appears to be, as judged by the ordinary methods. Professor Vose used to say that there are many bridges that are kept from falling "only by the grace of God and the force of habit." There are certainly many which depend upon some means of transmission of loads to the abutments that no self-respecting engineer would rely upon in designing, though recognizing and taking advantage of it sometimes in a critical investigation of an existing bridge. For instance, a rapidly moving electric car may skate safely across a short span or a single panel which would be unsafe for the same car even to stand on. Another example is found in the fact that a bridge may be safe for a car electrically driven when it would be unsafe for a steam locomotive of the same weight, on account of the difference in the mode of transmission of the power to the driving wheels, rotary in the one case and reciprocal in the other. These are cases which show a reduction of strain on stringers often greater than would be the increase of strain due to the sudden application of a load. Track rails (and jack stringers when used) add materially to the carrying power of stringers of short spans, especially if the rails are heavy. Guard rails and even guard timbers and the stiffness of the car itself give some help; also the continuity of the stringers of a truss bridge when the stringers are framed into the floorbeams and riveted to them. The stiffness of truss chords may make the strength decidedly greater than would be determined by considering each intersection as if it were a joint with a fractionless pin, instead of a continuous riveted box girder, as may be the case.

Rivets and Pins

A very marked instance of greater strength than is assumed in the ordinary methods of calculation is the case of rivets and pins. A large factor (indeed probably the main factor) in the real strength of a riveted joint is the friction of the members upon each other under the pressure of the gripping of the rivet. W. J. Watson, in a paper presented to the American Society of Civil Engineers in 1906, assigns to this friction a value of 14,000 lbs. per sq. in. of cross section of rivet for one plane of contact (or when acting in single shear) and 18,000 lbs. per sq. in. for two planes of contact (or in double shear). The present author would hesitate to give definite mathematical value to this friction, since probably no two rivets exert the same pressure. But it is axiomatic that this friction is great only while the rivet is tight; as soon as the rivet becomes loose it is an entirely different story. This value of a riveted joint is so great and so evident that account of it is taken in the author's modifications of the specifications of the Massachusetts Public Service Commission. In calculating pins it is customary to assume that the pressure of each member upon the pin is concentrated at the centre line of its bearing surface, whereas the fact is that, before a pin would fail by bending, the pressure of each member would become concentrated at that edge of the member which would give the minimum bending moment. This makes the real bending moment on most pins only a small fraction of that obtained by using the ordinary assumptions. An examination made by sawing through the line of flange rivets of an iron floorbeam removed nearly 30 years ago showed the rivets in exceptionally good condition, though by the accepted method of calculation they had been subject to 80,000 lbs. per sq. in. in shear and 130,000 lbs. per sq. in. in bending. In the same bridge, pins which were figured to have a moment of 300,000 lbs. per sq. in. bending, were found to show no slightest sign of overstrain.

*From a paper presented before the Brooklyn Engineers' Club.

Another matter, the importance of which is often greatly overestimated, is the secondary stresses due to large gusset plates at joints of riveted trusses. In most cases where youthful engineers speak with awe of the "terrible secondary stresses," they overlook the added value given to the members by stiffening them through the length of these gussets, thereby reducing the unsupported length of the members, and also giving them "fixed ends." This remark should not be understood to give approval to eccentric connections, for these should always be avoided if practicable, and the eccentricity reduced to a minimum when it cannot be altogether avoided; it is simply intended to call attention to a side of the question which is sometimes overlooked. If one were to judge by the school of specialists on the "secondary stress" bugaboo, pin-connected trusses would be the ideal construction for all bridges, long or short; whereas the greater rigidity or stiffness of riveted trusses makes them far more durable, especially for moderate and short spans; while plate girders, for a similar reason, are still better for lengths for which their use is practicable.

Reduction of Vibration

The importance of rigidity and reduction of vibration, not only in prolonging the life of a bridge but also in increasing its strength when new, can hardly be overestimated. Its advantage in increasing the confidence of the public is also real and important. Time was when some engineers delighted in pointing out the "spidery" structures of their designing, with pride that they could perform such marvels. The cost, or amount of material used in such cases may have exceeded what would have sufficed for a structure that would appear, and really be, much more substantial.

Effect of Track Position

The capacity of a bridge for track loads is far more affected by the position of the track than is generally appreciated. It is frequently found that a track which, according to the plans, should be centered with the bridge is considerably off centre. As an illustration of the effect of this "eccentricity," take the case of stringers 5 ft. on centres, and the centre of the track 1 in. to one side of the centre of stringers; this causes a strain on the nearer stringer 3⅓ per cent. greater than if the track were on centre. The eccentricity of a track is likely to change from time to time, especially on a curve and particularly near its ends. Because of possible changes in the eccentricity, it is the practice of the author, in making up the figures for moment and shear, for inspection reports, to make them first as if the track were on centre and to make a separate item for the excess due to eccentricity of more than about ½ in.

Shear Due to Sidewalks

An overhanging sidewalk, similarly, adds more than its weight and that of its load to the strain in the nearer truss. Reduction of moments in floorbeams by such overhanging sidewalks is disregarded in the author's calculations, on account of the possible temporary removal of the sidewalk. But the increase in shear due to such sidewalk is given its due importance.

Roadway and Sidewalk Loads

Sometimes engineers are known to argue that no impact allowance need be made with roadway and sidewalk loads, though it seems strange that anyone should hold this opinion. The specified 100 lbs. per square foot is no doubt sufficient to provide for as large a crowd on a sidewalk as can move with such speed and harmony as to exert the additional force ordinarily included in the term "impact," unless the gathered crowd is expected to "cheer with its feet." But even for sidewalk loads there is a possibility of a greater weight than the sum of the specified weight and the specified impact. Prof. L. J. Johnson, in experiments made in 1904, obtained a weight of 181 lbs. per square foot. In reporting the experiments to the Boston Society of Civil Engineers, Prof. Johnson says: "Though 181 lbs. per square foot must be conceded to be an extreme, it is believed that something very close to that figure is reached, over the whole drawbridge on the way from Soldiers' Field to Harvard Square

after one of the great football games"; and he adds: "The conclusion seems irresistible that loads of 180 lbs. per square foot may actually occur in exceptional cases; that 160 lbs. must frequently occur; that 140 lbs. must be common on station platforms, in corridors and in many other places frequented by throngs of people." In the present day of rapid giant automobile trucks, the case for roadway loads is different. One such motor truck for which data are available has a weight of 17 tons on an over all area of 140 sq. ft., or 243 lbs. per square foot, when carrying no more load than its rated capacity. As there is no inspector at the junction points of highways, it is altogether probable that the overload on such trucks is not kept down to the 10 per cent. common with freight cars, and the actual load may be expected to run up sometimes to 300 lbs. per square foot of the space occupied when the truck is at rest. (Trucks with much greater weights per square foot than this are operated in this city, but they are reported as never used on bridges.) Of course, the whole roadway of a bridge would not be covered with such trucks in close contact both longitudinally and transversely; and if they were so placed, they would not be able to operate at speed. But such loads covering a third of the roadway area would be quite possible and might run at moderate speed. That the specified allowance for impact is none too large for such loads, any observing man will admit after seeing and hearing such trucks run across a bridge with a plank floor, or one on which even small pebbles are found.

Errors of Erection

If errors in erection have been found, so that members are transposed or misplaced on the pins, or if a test with the hammer indicates uneven distribution of stress between the pairs or sets of tension members intended to work together, due attention must be given to these facts in determining the capacity of the bridge.

Composite Stringers

Composite stringers, as two or more timbers or beams of different depth, or flitched beams with timber between I-beams or channels, present two possible conditions to the investigator. If the component parts are constrained to equal deflection, the load is considered as distributed in the way which would cause such equal deflection, in which case the capacity of the combination is less than the sum of capacities of the components. If unequal deflections may take place, the distribution of the load is determined by the theory of least work, or so as to produce equal unit stresses in the extreme fibers, if of similar material, or proper relative stresses if of unlike material.

Safety of Derailed Cars

Any type of construction which makes no provision for the safety of a derailed car is very undesirable. One such which seems to be popular is a flitched beam with the rail spiked directly to the timber stringer, which is bolted between two I-beams or channels, with no floor between the stringers at all adequate to support a car if it leaves the rail. Another similar construction is a double stringer of I-beams or channels with spiking pieces between, which rest on horizontal separators of short pieces of channel riveted to the beams. Fortunately, many bridges with such stringers have heavy plank floors laid on top of the stringers, so providing for the safe passage of a derailed car if it does not get too far away from the track stringers. A danger in many highway bridges is that a car may leave the rails and the support provided for it and get on to that part of the bridge where the stringers were designed for lighter loads; perhaps also nearer the centre of floorbeams competent to carry a car only near one end.

Investigation of Compression Members

Compression members should sometimes be investigated on three different bases, each with its proper length and radius of gyration:—

(a) In the plane of the truss.

(b) In the plane of the members, perpendicular to the plane of the truss.

(c) In a plane normal to the least radius of gyration of the member or of one of its components.

In case (a) the effective length may be taken as the distance between centres of connections (or sometimes less) instead of the distance between the theoretical panel points.

Pony trusses without proper side support for the top chords call for careful consideration as to what should be taken as the unsupported length of such chords. No general rule for such cases can be laid down, but each must be considered on its own merits, according to the specific conditions.

Riveted Connections

The value of a rivet whose grip is more than four diameters is decreased about 1 per cent. for each 1/16 in. of this excess. Attention may here be called to the fact that the diameter of a rivet which fills the hole is 1/16 in. greater than its diameter before driving.

Rivets in reamed holes, if equally well driven, are worth much more than in punched holes for several reasons:—

(a) Because in the reamed hole the rivet upsets more readily to completely fill the hole;

(b) Because it has its full section for its full length without a possibility of offset or shoulder;

(c) Because, on account of both facts just mentioned, the rivet also exerts greater pressure on the parts riveted together, increasing the friction between the surfaces in contact;

(d) Because whatever burr is formed in reaming the hole adds to the friction between the parts.

The rivets of top flanges of deck girders and stringers, especially in very old bridges, are sometimes found to be insufficient for local loadings.

In riveted connections the spacing is often so close as to leave insufficient metal between to develop the rivets. If this is found to be the case the value of the net section is used, rather than the rivet value, in determining the value of the detail. The same trouble is often found near the ends of a girder, where the desire to save 1/16 in. in the thickness of the web leads the careless or ignorant designer to crowd the rivets unduly. This reduction of thickness of web is in other ways not always real economy, as it may necessitate additional stiffeners costing more than is saved in the web.

Floorbeams

End floorbeams of swing bridges or of fixed spans adjacent to such bridges are often found to be lighter than the intermediate floorbeams, through a mistaken notion that the loads for these floorbeams are only half as great. As a matter of fact, the actual live load is usually much larger (often double or even more), and even the dead load is sometimes greater than on the intermediate floorbeams, for the overhang of the floor gives not only an extra loaded length, but also a leverage which makes the force acting on the floorbeam greater than the weight of the load itself. In addition to the direct loads, the extra impact due to the open space between the fixed and movable spans adds greatly to the effect of the live load, which is still further increased by a possible difference in level of the floors of the two spans.

Pedestals and Rockers

Often pedestals for truss bridges, and sometimes rockers for long plate girders, are found to be too short to provide fully for longitudinal thrust or webs are too thin to support their loads and resist transverse shocks without stiffening diaphragms. In a similar way pin plates on compression members of pin trusses, or joint gussets of riveted trusses, are frequently found to be too thin to give a radius of gyration for the unsupported length of jaws comparable to the radius of gyration of the member as a whole for the whole length of the member.

Loop Hangers

Loop hangers for floorbeams are frequently found to be deficient in the details. Loop hangers of liberal size may bear upon clip angles which have insufficient strength, either in themselves or by stiffeners bearing upon them, to prevent

bending up from the weight which they have to carry. Sometimes insufficient rivets are used in connecting such clip angles to the floorbeams. Even when a loop hanger passes down through or around both flanges of a floorbeam and takes bearing on the bottom flange angles, if there is no tie plate or only a thin loose washer plate, these angles and washers are very often found to be insufficient.

Decay of Timber Stringers

The reduction of the strength of timber stringers due to decay is not always appreciated. That the unit stresses generally allowed for timber leave a larger factor of safety above the elastic limit than is commonly left in the case of steel members is realized. This is wise, because wood exposed as is usual on bridges, deteriorates more rapidly than steel or iron which receives reasonable care. But, regardless of the reduction of strength of individual fibers which, though not so far gone as to be called rotten, are approaching that stage, a slight loss of section in the top or bottom of a stringer reduces the strength for resistance to bending altogether out of proportion to the amount of section lost. In a timber beam 12 in. deep a loss of 1 in. in depth reduces the section 8 per cent. and the strength 16 per cent.; 2 ins. in depth reduces the section 17 per cent. and the strength 30 per cent.; 3 ins. in depth reduces the section 25 per cent. and the strength 44 per cent.; 4 ins. in depth reduces the section 33 per cent. and the strength 55 per cent.

If the decay is uneven the loss of strength is even more striking. A 12-in. stringer having full depth at one side and reduced at the other side 2 ins. has its section reduced 8 per cent. and the strength reduced 28 per cent.; 4 ins. has its section reduced 17 per cent. and the strength reduced 46 per cent.; 6 ins. has its section reduced 25 per cent. and the strength reduced 58 per cent.; 8 ins. has its section reduced 33 per cent. and the strength reduced 66 per cent.

Sound timber, notched for pipes or other obstructions, would be reduced by these ratios; but in considering decayed timber it must be remembered that there is not a sharp dividing line between sound and rotton wood. Hence it is not wise to increase the allowed unit stress in timber for the consideration of existing structures above the amounts given in the specifications, particularly as decay in timber is wont to proceed rapidly when once started. Oak, chestnut, ash, and to a less degree, spruce timber, may lose a great part of their original strength while still showing little change in their appearance.

Corrosion and Bolt Holes

Corrosion and bolt holes in flanges of rolled steel beams reduce the strength far more than is generally realized. Of course the fact is known when thought of, but it is too commonly overlooked. The following figures illustrate these cases:—

If a 12-in.-31½-in. I-beam used as a stringer has 1 hole ⅞ in. in diameter in one flange, the strength is reduced 12¼ per cent.; 1 hole ⅞ in. in diameter in each flange, the strength is reduced 14¼ per cent.; 2 holes ⅞ in. in diameter in one flange, the strength is reduced 24½ per cent.; 2 holes ⅞ in. in diameter in each flange, the strength is reduced 28½ per cent.; ⅛ in. thickness rusted from one flange, the strength is reduced 15¼ per cent.; ⅛ in. thickness rusted from each flange, the strength is reduced 19 per cent.

If a 12-in.-20½-in.-lb. channel used as a stringer has 1 hole ⅞ in. in diameter in one flange, the strength is reduced 17¾ per cent.; 1 hole ⅞ in. in diameter in each flange, the strength is reduced 21½ per cent.; ⅛ in. thickness rusted from one flange, the strength is reduced 15 per cent.; ⅛ in. thickness rusted from each flange, the strength is reduced 18¾ per cent.

Spacing of Ties

Ties should be spaced not more than 8 ins. apart in the clear (6 ins. is better), or a derailed car wheel will drop so low between the ties as to cause too great pounding. They should be notched not less than ¾ in. for the stringers and attached to them by hook-bolts or some suitable substitute at every third tie. There should be not less than 6 ins. thickness of timber above the dapping. For wide spacing of girders or stringers, or when one rail is elevated while the stringers are at the same level, deeper ties may be required.

Guard Rails

Inside guard rails are a very important adjunct to a bridge carrying a track, to prevent the wandering of a derailed car; such guard rails should be fully spliced or their efficiency will be greatly reduced. Care should be taken that bolts are so placed that neither heads nor nuts can be sheared off by a derailed car. Some engineers do not realize that outside guard timbers do not answer the same purpose; and the requirements of at least one Railroad Commission until recently called for lining angles on these timbers, apparently with this misunderstanding. A brief consideration of this subject will show the fallacy of this view; if a wheel is retarded by rubbing against the inside rail, it will tend to turn the axle a little, directing the car toward its normal location; but the retarding of a wheel by rubbing on the outside guard timber will swing it further out of line and away from its proper place. This change of direction, too, will throw it against the guard more nearly at right angles, thus making it more likely to climb the guard and leap into whatever disaster is lurking beyond.

Though the outside guard timbers are not qualified for guiding a derailed car, they do have a very important office. Without them or some substitute, the ties would be likely to become bunched; the guard timbers also help to distribute the load and reduce the danger that the ties will tip up under a derailed wheel when stringers are too closely spaced. Guard timbers should always be notched over the ties and should be bolted to at least every fourth tie. Splices should have a horizontal lap joint.

PUBLICATIONS RECEIVED

IRVING SUBWAY.—Pocket-size catalogue (No. 2-A), issued by the Irving Iron Works Co., Long Island City, New York, illustrating and describing the "Irving Subway," a fireproof, ventilating flooring for power houses, industrial plants, etc.

PUBLIC WORKS REPORT.—Report of the Minister of Public Works for the Province of Ontario for the twelve months ended October 31st, 1918; 100 pages and paper cover; 6½ by 9½ ins. Contains the reports of A. J. Halford, Engineer of Public Works; C. H. Fullerton, Superintendent of Colonization Roads; and F. R. Heakes, Provincial Architect.

EMPIRE MUNICIPAL DIRECTORY AND YEAR-BOOK.—Published by the Sanitary Publishing Co., Ltd., 8 Breams Bldgs., London, E.C., England. This directory is in its 37th year of publication. It consists of lists of local authorities and officials in the United Kingdom and all of the British dominions and colonies; 272 pages and cover, 7 by 9½ ins., cloth bound; price, $1.50 postpaid to Canada.

CERTAIN LINES IN ONTARIO AND QUEBEC.—By F. B. Reid, supervisor of levelling, Geodetic Survey of Canada. Published as Publication No. 4 of the Geodetic Survey. This pamphlet describes bench marks from Montreal to Hull, P.Q.; St. Martin Junction to Three Rivers, P.Q.; Grenville, P.Q., to Prescott, Ont.; Ivanhoe to Toronto, Ont.; Bethany to Port Hope, Ont.; Myrtle to Whitby, Ont.; North Toronto to Mimico, Ont. It also includes an index and map showing all work previously published.

THE JEFFREY CARRIER.—Cloth-bound book, 96 pages and cover, 6 by 9¼ ins., distributed gratuitously by the Jeffrey Manufacturing Co., Montreal, P.Q., and Columbus, Ohio; published in three colors on coated paper, profusely illustrated. This booklet describes the pivoted bucket conveyer and is published as catalogue No. 210. It is so full of useful data concerning carriers, has so many illustrations of various installations, and is so well printed and substantially bound, that it will prove a desirable addition to the engineer's library.

ECONOMICAL SIZE OF PIPE FOR GIVEN LOSS OF HEAD*

By Prof. E. W. Rettger
Cornell University

THE most economical size of penstock is a matter of the greatest importance when the penstock is a long pipe under high head. In such a case the first cost of the penstock is apt to be the largest part of the total first cost of the plant and it is therefore very important that the most economical size of the penstock be determined.

Before the most economical size of penstock can be determined, it is necessary to know what principal of economy is to be used. This principal may be different for different plants. For instance, it may be required to determine the size of the pipe so that the total net annual income shall be a maximum, or so that the percentage return on the original investment shall be a maximum. In other cases it may be required to determine the pipe so that the percentage return on the original investment shall be a specified amount. This may be the case when the amount of water available is limited and when it is imperative to produce as much power as possible, consistent with a fair rate of return on the original investment. Thus, the economic design of a penstock may come up in a variety of forms.

When the penstock is to consist of a pipe of constant diameter throughout, the problem, so far as the penstock is concerned, is comparatively simple. Assume, for instance, that the net annual income shall be a maximum. A simple and direct method of procedure in determining the economical size of pipe of constant diameter throughout, under the given principle of economy, is as follows:—

Calculate or approximate the total net annual income for each of several assumed diameters. With the diameters as abscissae and the total net annual income as ordinates, a curve may be plotted. From this curve, the diameter can be found for which the total net annual income will be a maximum.

In the case of high heads, however, it is often found economical to make the pipe consist of two or more sections of different diameters. Such a pipe would approximate the shape of a funnel with the smallest diameter where the head is the highest. In other cases it is found economical to make the upper part—the part under the low head—consist of concrete or staves and the remainder of steel. The determination of the economical pipe now reduces to the determination of the diameters of the several sections and the problem may not be an easy one. The method of procedure suggested for the case of a pipe of constant diameter throughout, is no longer applicable. While considerable latitude is left to the designer, it is nevertheless important to be able to determine what the theoretically economical diameters of the several sections are.

In 1907, A. L. Adams proposed a principle for the design of a penstock that seemed to him self-evident. This principle may be stated as follows:—

That pipe is most economically designed for which the interest and depreciation on first cost of the pipe plus the annual value of the power lost due to friction in the pipe is a minimum.

This principle of economy seems simple and logical and it is referred to in nearly every discussion on the economical size of penstock. Frequently, formulas for the economical diameter are derived from it. For the case of riveted steel, Professor D. W. Mead (Mead's Water Power Engineering, 2d edition, page 546) derives two formulas:—

$$(1)\quad d=0.2153\sqrt[7]{\frac{fbq^3S}{cih}} \text{ for high head}$$

and

$$(2)\quad d=0.2195\sqrt[6]{\frac{fbq^3}{t'ci}} \text{ for low head}$$

where h is the head on the point under consideration; f is the coefficient of friction defined in equation (3) which follows; S is the allowable unit stress in shell in pounds per square inch corrected for rivet holes and water hammer; c is the cost of the metal per pound; i is the rate of interest and depreciation on first cost of pipe; b is the annual value of a horsepower at the wheel; and q is the discharge in cubic feet per second.

When the required theoretical thickness of the shell is more than the minimum allowable thickness, the pipe is considered to be designed for high head and formula (1) applies. When the theoretical thickness of the shell becomes less than the minimum allowable thickness, formula (2) applies, which was derived on the asumption that the thickness of the shell shall be the minimum allowable thickness, t'.

From formula (1) it is seen that the theoretically economical diameter of a pipe under high head decreases as the head h, increases; and from (2) it is seen that the economical diameter for a pipe under low head is independent of h.

In deriving formulas (1) and (2) the friction head was assumed to be given by

$$(3)\quad h'=\frac{fl}{d}\cdot\frac{v^2}{2g}.$$

Now f is unknown to start with since it depends upon the diameter of the pipe which is not yet determined. In practice, a value of f is first assumed, and the diameters of the pipe are determined by means of the above formulas. If the average value of f for the pipe so determined differs appreciably from that assumed, a revised value for f is taken.

If the friction head for riveted steel pipes is assumed to be given by the formula

$$(4)\quad h=0.00050\ \frac{v^2\,l}{d^{1.25}}\ ;$$

the resulting formulas become:

$$(5)\quad d=0.1423\sqrt[7.25]{\frac{bq^3S}{cih}} \text{ for high head;}$$

and

$$(6)\quad d=0.1356\sqrt[6.25]{\frac{bq^3}{t'ci}} \text{ for low head.}$$

Formulas (5) and (6) do not contain the unknown coefficient f. So far as the writer knows, formulas (5) and (6) are here given for the first time.

If the value of b, the value of a hydraulic horsepower at the wheel, is given, Adams' principle and the resulting formulas will solve the problem. Unfortunately the proper value for b is not always known. As already stated the principle of economy to be used in the design of a penstock may be one of several, and Adams' principle may be difficult to apply. Engineers of experience declare that this principle is not always applicable. These considerations urged the writer to see if a method of attack analogous to that suggested for a pipe of constant diameter throughout could be used, and as a result he has arrived at certain conclusions that may be of interest to students of hydraulics.

If for an assumed total loss of head h', the most economical pipe could be found, the following method would be applicable: For each of several assumed values for the total loss of head, h', in the pipe, determine the economical pipe, and if, the total percentage return, p, is to be a specified amount, calculate or approximate the *percentage return* for each assumed value of h'. A curve can then be drawn with h' as the abscissa and p as the ordinate. From this curve the value of h' can be obtained so that the percentage return shall be the desired amount. Now with h' determined, the most economical pipe can be found.

If the pipe is homogeneous—made entirely of riveted steel for instance—the pipe of least annual cost will be the pipe of least first cost, or of least amount of metal. If the pipe is not homogeneous, such as when the upper part is of staves and the lower part of steel, it is no longer a question of least amount of metal but rather one of least first cost or least annual cost. As shown later, the expression that will determine the diameter of the pipe for least annual cost will also determine the pipe for least first cost or least amount of metal (pipe homogeneous) if one or two of the

*From the "Cornell Civil Engineer."

constants involved are made equal to unity. It will be convenient therefore, to consider the case of least annual cost. The problem may be stated as follows:—

Given a pipe of fixed length, l, and under a given head, h, with a given discharge, q, it is required to find the size of the pipe so that for a given or assumed total loss of head, h', in the pipe the annual cost of the pipe will be a minimum.

The problem as thus stated is of considerable interest. In the "Engineering Record" of December 20th, 1913, page 682, E. R. Bowen describes the inverted Jawbone Syphon of the Los Angeles aqueduct. This inverted syphon was to be designed to contain the least amount of metal subject to the condition that the loss of head due to friction in the syphon should be 26 feet. The solution as given by Mr. Bowen is a graphical one requiring a great deal of labor. This same problem could have been solved in a much simpler way.

The annual cost of the pipe is the interest and depreciation on first cost and this will be represented by I. The The problem then is to find the size of the pipe so that I will be minimum, subject to the condition that the total loss of head in the pipe shall equal h'.

In practice, the pipe is made to consist of two or more sections, each section of constant diameter and thickness of shell. The greater number of sections, the more nearly will this pipe approach the theoretically most economical pipe, one in which the diameter decreases as the head increases.

For the sake of convenience we will assume that the pipe is to consist of three sections as shown in Figure I.

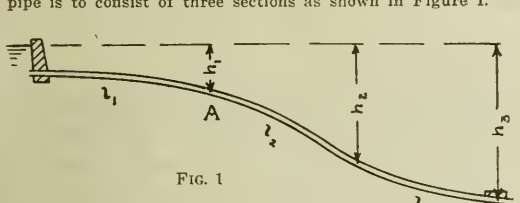

FIG. 1

Let l_1, h_1, d_1; l_2, h_2, d_2 and l_3, h_3, d_3 be the lengths, heads and diameters of the respective sections.

Evidently, the location of the points of division a and b will effect the economy. It can be shown that the location of the most economical points of division depends upon the profile. These points, perhaps, can best be found by trial. For our purpose it is necessary to assume that the points of division are given. Consequently h_1 and l_1, h_2 and l_2, h_3 and l_3 are assumed as given or determinate.

The interest and depreciation on first cost of a section is proportional to the amount of metal in that section. Using a well known principle of hydraulics, the amount of metal in that section under high head is found to be proportional to $d_r^2\, h_r\, l_r$. The subscript r is used to indicate that it applies to a section and not to the pipe as a whole. The annual cost (interest and depreciation) of this section may therefore be represented by the equation

(7) $I_r = A d_r^2 h_r l_r$;

where A is a constant. Moreover, the friction head for this section may be expressed by (see eq. 3)

$$h'_r = \frac{f l_r}{d_r} \cdot \frac{v_r^2}{2g}$$

or, if v is eliminated by means of the relation $F_r\, v_r = \frac{1}{4}\pi d_r^2\, v_r = q$, by

(8) $h'_r = \frac{C l_r}{d_r^5}$;

where C is a constant. The problem then requires us to find d_1, d_2, and d_3 so that

(9) $I = I_1 + I_2 + I_3 = A\ (d_1^2 h_1 l_1 + d_2^2 h_2 l_2 + d_3^2 h_3 l_3)$

will be a minimum subject to the condition that

(10) $h' = h'_1 + h'_2 + h'_3 = C\left(\frac{l_1}{d_1^5} + \frac{l_2}{d_2^5} + \frac{l_3}{d_3^5}\right)$

shall have a specified value. If, now λ is a constant, the expression,

(11) $L = I + \lambda h'$,

will be a minimum when I is a minimum. Since h' shall have a definite value, it may be considered a constant. Substituting the values of I and h' as given by equations (9) and (10) and rearranging, equation (11) becomes

(12) $L = (I_1 + \lambda h'_1) + (I_2 + \lambda h'_2) + (I_3 + \lambda h'_3) = L_1 + L_2 + L_3$

For an assumed mode of division of the pipe into sections, h_r and l_r are given for each section and therefore must be considered as constants. Consequently L_1 contains d_1 as the first variable. Similarly, L_2 contains d_2 as a second variable and L_3 contains d_3 as the third variable. L_1, L_2, and L_3 contain no variable in common and they are therefore independent functions. From this it follows that if their sum must be a minimum, each separately must be a minimum. That is, we must have separately

(13) $\frac{d L_1}{d (d_1)} = 0 \qquad \frac{d L_2}{d (d_2)} = 0 \qquad \text{and} \quad \frac{d L_3}{d (d_3)} = 0.$

Or in general [see eq. (11)],

(14) $\frac{d L_r}{d (d_r)} = \frac{d I_r}{d (d_r)} + \lambda \frac{d h'_r}{d (d_r)} = 0$

for each section of the pipe.

Since λ is a constant, yet to be determined, we may arbitrarily let

(15) $\lambda = \frac{b\, q}{8.8}$

and consider b the constant yet to be determined. Substituting in equation (14), we obtain

(16) $\frac{d L_r}{d (d_r)} = \frac{d I_r}{d (d_r)} + \frac{b\, q}{8.8} \cdot \frac{d h'_r}{d (d_r)} = 0$

for each section of the pipe.

From equations (7) and (8), it is seen that l_r is a factor of equation (16). Dividing through by l_r and performing the differentiation indicated, the resulting equation becomes identical with that derived by Prof. Mead (Water Power Engineering, page 546). Formula (1) therefore, gives us the required diameter for any section under high head and formula (2) for low head. The value of h to be used in formula (1) when applied to any section should be of course the highest head that section is under.

In the present interpretation of formulas (1) and (2), b is not to be considered as the value of a hydraulic horsepower at the wheel, but as a constant or parameter such that the total loss of head in the pipe shall be h'. Although a constant, b is not arbitrary, but its value must be determined. This can be done in the following way: For riveted steel pipes, the diameters as determined by formulas (1) and (2) must satisfy the equation [see equation (10)]

(17) $h' = C\left[\frac{l_1}{d_1^5} + \frac{l_2}{d_2^5} + \frac{l_3}{d_3^5} + \ \ldots\ \right]$

If, therefore, the values of d_1, d_2 and d_3 as given by formulas (1) and (2) be substituted in equation (17), the resulting equation will contain b as the only unknown, and therefore b is determined. If, for instance, the first section is under low head and the other two under high head, d_1 is given by formula (2) and d_2 and d_3 by formula (1).

Instead of determining b algebraically as was suggested above, a value for b may be assumed and the diameters determined by means of the formulas. A few trials will suffice to determine b so that the total loss of head in the pipe line will be h'.

Since for a given mode of division of the pipe line into sections, h' is determined as soon as a value for b is assumed, the formulas (1) and (2) may be given a new interpretation. According to this interpretation b may be taken as a parameter such that for every assumed value for b, the resulting pipe line will, for the resulting total loss of head in the pipe, be the pipe of least annual cost (or least first cost or least amount of metal). This interpretation, so far as the writer knows, is here given for the first time.

In special cases b may be taken as the value of a hydraulic horsepower at the wheel. The new interpretation, however, still holds since the pipe as thus determined

will be the most economical pipe for a particular loss of head. The new interpretation of formulas (1) and (2) (and all other formulas of the same nature) is therefore the general interpretation, and these formulas as an expression of Adams' Rule become a special case.

The economical size of a penstock or pipe may now be determined in a manner analogous to that suggested for pipes of constant diameter throughout. If, for instance, the percentage return on the original investment shall be a specified amount, we may proceed as follows:—

For each of several assumed values for b determine the pipe and calculate or approximate the percentage return p. With b as abscissa and p as ordinate a curve may be drawn. From this curve that value for b may be obtained for which the percentage return is the specified amount.

Illustrative Problem

A hydro-electric plant is to be designed so that the gross percentage return on original investment shall be a specified amount. The pipe is to be riveted steel. Besides the data given in the figure, let $q=50$ cu. ft. per sec.

$S=10{,}000$ lbs. per sq. in.
$t'=\frac{1}{4}$ in. as a minimum value
$c=\$.05$
$i=\$.12$

Since the pipe is homogeneous, the pipe of least annual cost is also the pipe of least amount of metal. We may if we choose, let $c=i=$unity (or we may let $\frac{b}{ci}$ be the constant) and design for minimum amount of metal. The final results will not be affected. We will design therefore for least annual cost.

As a first trial let $b=50$.

To eliminate the unknown coefficient of friction, f, use formulas (5) and (6). From (6)

$$d_1=0.1356\sqrt[6.25]{\frac{b\,q^3}{t'\,ci}}=4.35 \text{ ft.}$$

Run this section (low head) down to $h_1=220$ ft.

Divide the rest of the pipe line into three sections as indicated in figure. From (5)

$$d_2=0.1423\sqrt[5.25]{\frac{b\,q^3S}{ci\,h_2}}=3.70 \text{ ft.}$$

$d_3=3.50$ ft.
$d_4=3.35$ ft.

For the pipe thus determined, the total investment may be calculated, and the total annual income approximated. If the percentage return is the amount specified, the problem is

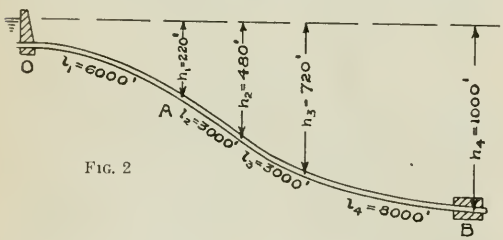

FIG. 2

solved. If not, another trial value for b should be shown. In fact several trial values for b may be successively chosen and a curve drawn with b as abscissa and p, the percentage return, as ordinate. From this curve the proper value for b can be found.

With the diameters of the four sections as determined above, the total loss of head in the pipe line is found to be $h'=49$ ft. The above pipe then for $h'=49$ ft., and for the particular mode of division assumed, is the most economical pipe that can be constructed.

It may be of interest to add the following: If the above pipe of four sections had been designed for a constant diameter throughout but variable thickness of shell, this pipe for $h'=49$ ft., would require 3.5% more metal. If the part AB, the part under high head and consisting of three sections, had been designed for a constant diameter throughout but variable thickness of shell, only 0.8% additional metal would be required. It seems advisable therefore to make the part AB have the same diameter throughout but to change the thickness of shell several times.

If the pipe had been considerably larger, the last statement would not hold. In such a case the saving in the amount of metal required if the pipe under high head is designed for several sections of different diameters and thickness of shell over that required if these sections are designed for the same diameter but different thicknesses of shell may be appreciable. In many cases, however, this saving is not enough to justify the expense of reducers.

The question therefore arises: What is the formula for a pipe or part of a pipe that shall consist of a certain number of sections all of the same diameter but different thicknesses of shell? This question can be readily answered. Referring to Fig. 1, assume that the three sections shall have the same diameter but different thicknesses of shell. Then [see equations (11), (9), (10), and (15)]

$$L=Ad^2\,(h_1\,l_1+h_2\,l_2+h_3\,l_3)+\frac{bq\,C}{8.8\,d^3}\,(l_1+l_2+l_3)$$

This must be a minimum. That is,

$$\frac{d\,L}{d\,(d)}=2Ad\,(h_1\,l_1+h_2\,l_2+h_3\,l_3)-\frac{5\,bq\,C}{8.8\,d^4}\,(l_1+l_2+l_3)=0.$$

Now let

$$(18)\quad h_e=\frac{h_1\,l_1+h_2\,l_2+h_3\,l_3}{l_1+l_2+l_3}$$

and solve for d, and we obtain, for high head,

$$(19)\quad d=0.2153\sqrt[7]{\frac{fbq^2S}{cih_e}}$$

as the required diameter of a pipe (or part of a pipe) that shall have the same diameter throughout but shall consist of a given number of sections of different thicknesses of shell. Formula (19) is the same as formula (1) except that h of (1) must be replaced by h_e as defined by (18). So far as the writer knows, formula (19) is here given for the first time.

Suppose that the part AB of the problem given above shall consist of three sections as shown and that these sections shall have the same diameters but different thicknesses of shell. From (18),

$$h_e=\frac{(3{,}000\times 480)+(3{,}000\times 720)+(8{,}000\times 1{,}000)}{3{,}000+3{,}000+8{,}000}=828 \text{ ft.}$$

Formula (1) or (5) may now be used if h is taken as 828 ft., and the resulting value for d will be the economical diameter of the part AB consisting of three sections of the same diameter but of different thicknesses of shell.

The Corrugated Bar Co., Inc., of New York, announces that it has taken over the entire assets and liabilities of the Corrugated Bar Co., a Missouri corporation, and is continuing the business of the latter company, which is in process of dissolution. This means the retirement by purchase of the Garrison interests, which held the majority of the stock of the Missouri corporation from its inception, in 1891, until the recent reorganization. The control now passes to A. L. Johnson, who has been connected with the company since 1895, and who is now its president.

An information service is being organized by the Associated General Contractors of America, who have established a general office at 111 West Washington St., Chicago, Ill. It is planned to have the manager of the service keep in touch with all the technical and trade papers, and to issue a special bulletin to contractors at least once a month, calling their attention to the best articles on all topics which will be of interest to them. This bulletin will be sent to all of the chief general contractors and construction engineers in the United States, whether members of the association or not, in the hope of stimulating the interest of all general contractors in problems of mutual interest and also in the work of the association.

CANADA'S FUEL PROBLEM — SOME NATIONAL AND INTERNATIONAL ASPECTS

(Continued from page 144)

south-western Alberta, and in the Flathead valley in south-eastern British Columbia.

"In northern Alberta there are enormous tar seepages which evidence an upwelling of petroleum unequalled elsewhere in the world. Along the Athabaska River they extend from Pelican Rapids to Fort McKay, a distance of over 100 miles. The known occurrences indicate that there is in sight at least 6½ cubic miles of bitumen, and the petroleum from which it was derived must have been many times greater. While this enormous amount of petroleum has escaped, there must be untapped reservoirs in the Devonian limestones, whence it was derived. Similar seepages occur near the Peace and Mackenzie Rivers.

"Near Peace River Landing, oil has been found in two wells, 900 and 1,100 ft. deep, respectively. The first well is reported to have yielded three to four barrels per day, when oil was struck in the upper portion of the tar sands and to have had a maximum production of about nine barrels. Drilling, however, was continued through the tar sands, which are about 80 ft. in thickness at this point, and a heavy flow of water and gas was struck immediately below the sands.

"The second well is in the tar sands and is reported to be yielding about 25 barrels per day."

There is marked evidence that Canadians are alive to the important possibilities of the petroleum industry, and the results of the efforts to be made in 1919 are looked forward to with the greatest interest.

Seeking Efficiency in Consumption

Canadians are recognizing the fact that it is fairly incumbent upon them to apply every permanent means within their power to utilize coal in the best and most efficient manner. It is recognized that coal shortage may recur, and therefore, the lessons of the recent shortage must not be forgotten. It is true that the lessons of the coal shortage of 1902-03 were all too soon forgotten, but surely those of the distressing times of the winter of 1917-18 will prove more lasting.

We must not forget the "heatless days"; the times when gasoline could not be used; the denial of fuel for certain luxuries, as use on private yachts; the curtailment of fuel for the manufacture of such apparatus as musical instruments, talking machines, etc.; the allotment to florists for greenhouse purposes of only 50 per cent. of the fuel they were accustomed to receive; the compelled use in certain districts of wood for fuel; the restrictions upon the use of natural gas; the prohibited use in many cases of anthracite and the substitution therefor of bituminous coal; the daylight saving legislation on both sides of the Atlantic; the cutting down of illuminated advertising; and the enforced "lightless nights." These and many other facts must be held in mind as indicating how wide-spread and absolutely necessary have been the efforts for economy with respect to fuel. In the period of reconstruction, and afterwards, the demand for fuel will doubtless be such that many of the restrictions placed upon its use during the war period will in one form and another find permanent expression.

Obtaining Greater Efficiency

In Canada, as in the United States, it is expected that coal consumers will endeavour to effect economies by the systematic employment of every reasonable means which modern progress can devise. Some of such means may suggestively be enumerated as follows:—

In the use of coal generally, great economies may be effected by subjecting the raw bituminous and lignite coals to such by-product and other manufacturing processes as will save the valuable by-products and at the same time produce from inferior grades a satisfactory and clean-burning fuel; by a proper co-ordination of the uses of electricity and coal according to their respective spheres of greatest efficiency; and by a greater utilization of gas. Those interested in the coal-gas-producing industries are looking forward to the greatly increased use of gas and the recovery of by-products, including the coke.* Manufacturers of stoves and heating apparatus are giving serious attention to the production of apparatus more suitable for satisfactorily burning the softer coals.

In the production of power, savings may be effected by taking advantage of the greater efficiency of the modern steam turbine and of large hydraulic units, and by the interconnection, especially over large areas, of various electric plants—whether steam-electric or hydro-electric, or combinations of both—with the object of securing the greatest efficiency in the supply of power and light to districts respectively served.

Effecting Savings of Fuel

By co-ordinated efforts by communities, savings may be effected by staggering the hours of closing of factories, by the adoption of the skip-stop system for street railways, by daylight-saving legislation, by the enactment and enforcement of wise laws, designed to eliminate the wastes resulting from the smoke nuisance.

In manufacturing establishments, savings will be effected by the more efficient use of light and power, by the elimination of uneconomical plants and processes, by the installation of means to use more economical fuel for direct heating, by the substitution wherever possible of hydro-electric for steam-developed power, and by standardization.

By the electrification of steam railways, especially if operated by hydro-developed power, enormous savings in fuel consumption may be made by the reduction of the amount of coal to be hauled, by the saving of energy resulting from the regeneration of electricity by improved methods of braking, by the reduction of the number of buildings and divisional points due to the greater radius of action of electric locomotives, and where fuel-power is employed, by its economical production in large, modern, generating stations. Canada is looking ahead to great development in the near future in the electrification of steam railways. The Ontario government and municipalities already have this problem in hand.

In all such efforts to attain the efficiency possible by intelligent saving and co-ordination, Canada may be relied upon not to fall short of her privileges. Recognizing that the days of the widespread use of anthracite are numbered, her bituminous coals and lignites will be subjected to by-product and other manufacturing processes with the object of producing a satisfactory and clean-burning fuel. Canada does not desire to ignore the march of progress in these fuel problems, nor will she be backward in effecting economies for the prevention of needless fuel and power wastes.

Canada Must Bestir Herself

Now, in conclusion, it must be recognized that anthracite as a fuel is a luxury. Within the last twenty-five years many farmers and citizens, especially in outlying communities where formerly only wood was used, now use anthracite. It became easier and more convenient for the farmer to haul his coal from the railroad siding than to go into the bush and chop his year's supply of wood.

A great portion of this Dominion, like the farmer, has become dependent upon others for coal.

Canada, even though she may regret being deprived of the luxury of clean-burning anthracite or the easily-delivered bituminous coal, must, nevertheless, arouse herself and bestow the necessary intelligent labor upon her own fuel resources in order to make them available for her national needs.

There is no necessity for Canada, with her vast resources of fuel and water power, to go cold or to have her industries throttled by reason of power shortage; but Canada may have a sore trial in both these respects unless every possible effort is speedily made to deal with the fuel and power situation in a comprehensive manner.

Once a broad national policy has been determined, financial and other assistance should be promptly rendered to

CENTRAL HEALTH LABORATORY REQUIRED

DR. C. J. HASTINGS, medical officer of health for the city of Toronto, is reported in a Toronto daily paper as having stated that practically every city is still experimenting with methods of sewage disposal, and that none have yet been able to solve the problem satisfactorily.

"We will be just as well to sit tight and watch experiments in other cities," says Dr Hastings, "as spend money for experiments here. All the so-called better methods are still in the experimental stage."

Dr. Hastings' policy of "sitting tight" and letting others experiment, is hardly the policy that one would expect from a progressive city like Toronto, and it is not likely the policy that the Works Department of that city will take.

Nevertheless, the attitude assumed by Dr. Hastings is not quite so selfish as might appear at first glance. It is undoubtedly founded upon one kind of logic. Milwaukee and other cities have spent many thousands of dollars upon experiments, and Dr. Hastings probably feels that these cities have gone much further in their experiments than Toronto could hope to go for a considerable period, and, as those cities are still spending money for this work, more or less freely, he naturally questions the necessity of Toronto's duplicating the work when he feels that it is already in good hands and is being capably carried out elsewhere.

But is this policy of waiting for "the other fellow" to solve one's problems, the best to pursue? Why should one city spend money in conducting experiments that are of general benefit to all cities? Milwaukee, having spent a certain amount of money in sewage disposal experiments, might very properly say: "We have done our share. Let's stop spending money, and let Toronto, Montreal or some other city finish the work." Then the work would be left to that city which had the most progressive, generous and far-sighted governing officials.

Dr. Hastings' remarks are another reminder that there should be some central bureau, or laboratory, fully equipped with funds and staff for conducting experiments in public sanitation. All problems of general application could then be referred to that bureau and properly taken care of, leaving only purely local problems to be solved by the individual municipalities. Now that the new Department of Health at Ottawa has an official and capable head in Dr. John A. Amyot as deputy minister, it is to be hoped that problems of this kind can be centralized under the direction of that department.

AN IMPROVED COST-PLUS CONTRACT

SEVERAL different forms of percentage contracts have been devised during the past few years in the United States, but a Canadian, J. A. Beatty, of the firm of Morrow & Beatty, Ltd., general contractors, Peterborough, Ont., has inaugurated a form of contract which appears superior in many respects to any other of its kind that has yet been suggested.

The Beatty plan, if it may so be called, has been tried out on a half-million dollar contract for the Southern Canada Power Co., and has resulted, says Mr. Beatty, most satisfactorily, both to the owners and their consulting engineers, and to Mr. Beatty's firm, who were the contractors.

Mr. Beatty's scheme is to charge (tentatively) a fixed fee of 20% on the estimated cost of the work and then, at the end of the job, to pay back to the owners 10% of the total cost of the work, whatever it may be. For instance, if a job were to be estimated by the contractors at a probable cost of $500,000, Mr. Beatty would charge a fixed fee of $100,000. When the job was finally completed, if it were found that the total cost amounted to $550,000, Mr. Beatty would pay the owners $55,000, leaving his firm a profit of $45,000. If the job had only cost, say, $475,000, he would pay the owners $47,500, leaving a profit for his firm amounting to $52,500.

At first glance this does not seem far different from a fixed fee with a bonus and penalty clause. Financially, it is practically no different, but it has two advantages, one of which, especially, is worthy of serious consideration.

First, it is a simpler and more clean-cut way of expressing the contractor's responsibility, and is less likely to result in disagreements or law suits. The owner knows that after he has paid or pledged himself to the fixed fee, whatever the cost of the work may be, he only has to pay 90% of it and the contractor pays 10%. In a simple arrangement of this kind, there is no room for unpleasant misunderstandings as to responsibility for cost having exceeded a certain figure. If the cost of the work be $1,000 or $1,000,000, the contractor pays 10%.

The second and more important advantage of the Beatty plan, the advantage that will appeal to every contractor, is its effect upon the contractor's staff.

Every man on the job knows right from the very beginning that his firm must pay ten cents of every dollar that is spent. When the contractor is not penalized until after the cost has reached a certain figure, the staff is likely to be less careful at the very beginning of the work, perhaps feeling certain that the work will not exceed the estimated cost, and that there is no need for stringent economy or for devising unique methods of saving every possible dollar; and not until the estimated cost has been reached, or nearly reached, and the work is seen to be far from completed, does the real situation impress itself upon the staff; then, when it is too late to prevent a penalty, every effort is made to finish up the job as economically as possible.

Mr. Beatty's plan prevents any laxity right from the start. The contractor and the staff know that they must pay one dollar out of the very first ten dollar bill that is spent on the work, and this direct liability is an excellent incentive to the contractor himself and to his staff to use

all possible brains and energy in carrying out the work in the most ingenious manner from the very first shovelful of excavation.

Engineers, and also contractors, differ in their opinions whether the lump-sum, or unit-price, contract is or is not preferable to the percentage contract. Many articles have been written upon both sides of the subject. But if the percentage contract is to be widely adopted (and it has grown a great deal in popularity during the last few years), we venture to predict that the Beatty plan will be tried by many firms, and that the contractors will find it a very satisfactory form of contract.

CANADA'S FUEL PROBLEM — SOME NATIONAL AND INTERNATIONAL ASPECTS

(Continued from page 151)

enable sane and businesslike development of Canada's lignite, peat and other fuel resources for the benefit of the nation, to be carried out by competent technical officials entrusted with this great and honorable responsibility. As we have already noted the work has been commenced.

Officials of the government of Canada, such as those in the Geological Survey, Department of Mines, the Commission of Conservation, and other organizations, have knowledge of existing conditions and of practical means by which much of the stress may be relieved. To carry out these measures of relief and to place Canada in a reasonably independent position with respect to fuel will take time; but there is no doubt that if matters are dealt with in a broad statesmanlike manner, and the necessary encouragement of financial and other assistance is given to those who are competent, Canada will, at a minimum of effort and expense, be relieved of a menace with respect to her coal supply which threatens not only her economic life, but the well-being of a large proportion of her citizens.

EXHIBITORS AT WATER WORKS CONVENTION

IN the June 19th issue of *The Canadian Engineer* there was published a list of the firms that exhibited at the American Water Works convention, June 9th to 12th, Buffalo, N.Y. It is very much regretted that several names were omitted accidentally from this list. In order to make the record of the meeting complete, it should be stated that in addition to the firms mentioned on page 550 of the June 19th issue, the following firms also had space: National Water Main Cleaning Co., New York City; Joseph Dixon Crucible Co., Jersey City, N.J.; United States Cast Iron Pipe and Foundry Co., Burlington, N.J.; Irving Iron Works Co., Long Island City, N.Y.; Badger Meter Manufacturing Co., Milwaukee, Wis.; McNutt Meter Box Co, Brazil, Ind.; Glauber Brass Manufacturing Co., Cleveland, O.; Richardson Phenix Co., Milwaukee, Wis.; and the Gaunt Co., Knoxville, Tenn.

The damage caused by a recent cloudburst along the line of the Canadian National Railways, between Port Arthur and Winnipeg, was of greater extent than indicated by early reports. Four to ten inches of rain fell during forty-eight consecutive hours. Several miles of roadbed, eight bridges and thirteen culverts were washed away. During the time necessary for repairs to be completed, C.N.R. trains ran on the C.P.R. tracks.

City Architect Pearse, of Toronto, says that the first draft of the revised building by-law is in the hands of the city solicitor. As soon as the latter official is through with it, the first draft of the by-law will be printed. Mr. Pearse says that in the revision of the by-law, three points have been kept in mind, in the following order of importance: First, safety of the public; second, fire protection; third, economy of design. Mr Pearse advocates the establishment in Canada of one or more laboratories for testing Canadian materials.

PERSONALS

LT.-COL. (DR.) JOHN A. AMYOT, C.M.G., of Toronto, has been appointed Deputy Minister of the Department of Health that was recently created by the Dominion Government. Dr. Amyot will go to Ottawa next week and will commence his new duties at once. Prior to going overseas in May, 1915, Dr. Amyot was professor of hygiene at the University of Toronto and director of the laboratory of the Ontario Board of Health. He went overseas with the No. 4 Canadian General Hospital of the University of Toronto. Upon his arrival in England, owing to his extensive experience in sanitation and public health work he was sent to France to take command of the sanitary section of the First Canadian Division. A few months later he was placed in charge of the sanitary organization of the Canadian corps. In September, 1916, his services were requested by the commanding officer of the Second British Army, of which he was appointed assistant director of medical services, in charge of sanitation. Dr. Amyot then had charge of all sanitary work extending from the North Sea to Ypres and Armentieres. He was mentioned in despatches in December, 1917, and was awarded the C.M.G. the following New Year's Day. During the last period of his overseas service, he was consultant on sanitation work to the commanders of the Canadian forces in England. He returned to Canada early last month and is at present enjoying a well-earned vacation. Dr. Amyot was born about 1869 in St. Agathe, P.Q., and was educated at St. Michael's College and at the University of Toronto, from which latter institution he graduated in 1891 with the degree of Bachelor of Medicine.

CAPTAIN DAWSON, recently assistant engineer, Halifax Ocean Terminals, is now practising in Montreal as a consulting engineer.

EX-SENATOR C. D. CLARK, of Evanston, Wyoming, U.S.A., has been appointed a member of the International Joint Commission, succeeding the late James Tawney, of Minnesota. The appointment was made this week by President Woodrow Wilson.

MAJOR T. E. RYDER, D.S.O., M.C., has been appointed general manager of the Rudel-Belnap Machinery Co., Ltd., Montreal. Major Ryder recently returned home in command of the 7th Canadian Siege Battery after having been overseas for four years.

LIEUT. J. E. PRINGLE, formerly of the Queen Victoria's Own Sappers and Miners, Indian Army (Royal Engineers), has been appointed to a position on the engineering staff of the Hydro-Electric Power Commission of Ontario. Lieut. Pringle will be engaged in location work in connection with the "hydro-radials" between Niagara Falls and Toronto.

In an interview with the "Toronto World," Dr. C. J. Hastings, medical officer of health for the city of Toronto, states that if the water of Lake Ontario were not treated, it would not be safe for the people of Toronto to drink it.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

BRIDGES, ROADS AND STREETS

Barrie, Ont.—The town council proposes to issue debentures to the amount of $10,000 for construction of cement sidewalks, crossings and improvements to roads.

Belleville, Ont.—Debentures will be issued to the amount of $6,635.06 for granolithic sidewalks and $32,871.06 for street pavements. Wilfred Holmes, city clerk.

Calgary, Alta.—The C.P.R. is reinforcing the concrete retaining wall on the Eighth St. W. and First St. E. subways in order to make them waterproof. Excavation is now being carried on along the retaining wall in order to put in th waterproof protection.

Cedardale, Ont.—Tenders will be received by Bowman and Connor, engineers, 31 Queen St. W., Toronto, until noon, July 19th, for the construction of a 73 ft. steel bridge with concrete abutments, or of a concrete arch truss bridge on the base line between Oshawa and Cedardale.

Chatham, Ont.—Tenders will soon be called for paving the River Rd. in Dover Tp. Plans and specifications are with W. C. McGeorge, chairman and engineer of the Roads Commission. There will be no curbing but merely a straight country road with three-foot gravel shoulders.

Cobden, Ont.—The county council has decided to take over the Cobden village road as a county highway. Reeve, W. J. Connelly.

Cobourg, Ont.—The part of the Kingston road, between Port Hope and Grafton, recently taken over by the provincial department of highways will be improved. In addition to grading, widening and draining, the department is putting in reinforced concrete bridges. Tenders have been awarded for 24-foot bridges on the road west from Cobourg, at Gage's Creek, and at Pontiac stock farm on the road east of the town, and at "Sidbrook," just outside the town limits. It has been recommended that the road running from the Home for the Aged to the corner of King and William Sts., be taken over by the department, and property be purchased to straighten the road near the corner of William St. and the Kingston road west of the town, which has a dangerous curve.

Compton, Que.—Contracts for gravelling Sherbrook-Norton road have been awarded to Francis Laroche, Coaticooke, Que.; F. E. Lovell, Coaticooke, Que.; R. E. Willard, Islandbrooke, Que., and L. D. Cairnie, Lennoxville, Que.

Cornwall, Ont.—Work is progressing favorably on the Ottawa-Prescott provincial highway in the neighborhood of Kemptville.

Daly, Man.—Contract for two reinforced concrete bridges and one culvert has been awarded by the municipal council to E. Fulcher, Brandon, Man.

Dundas, Ont.—The town council has awarded contract for 30-inch segment block to Toronto Potteries for $10,175.

Esquimalt, B.C.—Palmer Bros., Vancouver, have been awarded contract by department of public works for grading and paving Island Highway, 2¼ miles. Tender price, approximately $75,000.

Fenelon Falls, Ont.—At a meeting of the Victoria County Good Roads Board, a resolution was carried recommending the construction of a county road of asphaltic concrete, from Leddy Corners to the swamp. The construction is subject to the approval of the highways department.

Halifax, N.S.—The Canadian Bituminous Paving Co., Ltd., Toronto, has been awarded contract for all paving work advertised, with the exception of portions of three streets. The contract for bituminous macadam has been awarded to the Barrett Co., Halifax.

Halton County, Ont.—Contract for the middle road, of stone construction, a distance of 3¾ miles, and for the Milton road, 2¼ miles of waterbound macadam, have both been awarded. Work is expected to commence next week. Halton county intends expending about $130,000 on construction and maintenance this year. The county owns four stone-crushing plants; two of them only are working, one near Milton and the other near Nelson village, each having a capacity of about 100 yards of stone per day.

Hespeler, Ont.—The town council contemplates construction of cement sidewalks on George St. and Adam St. Mayor, L. E. Weaver.

Kingston, Ont.—The department of public works has awarded contract for placing of stone rip-rap along south walls of Lasalle highway, to John F. Sowards, Kingston.

Lindsay, Ont.—The Good Roads Board of the Victoria County Council has decided to construct one mile of permanent pavement in the township of Mariposa. Estimated cost between $20,000 and $27,000.

Lindsay, Ont.—The town council has requested the C.P. Ry. and G.T. Ry. to repair various street crossings in town.

Milton, Ont.—Halton county is at present building a large steel bridge over the ravine at Tansley, on the provincial county road. It is contemplated to construct a similar bridge over the Sixteen Mile Creek in Trafalgar township, about five miles from the Tansley bridge.

Montreal, Que.—A new road is to be built from Montreal to Mont Laurier, a distance of 140 miles. A. David, deputy minister of roads.

Montreal, Que.—Contract for pavements on Sherbrooke St. has been awarded by the city council to Quinlan and Robertson. Tender price, $85,656.

Morden, Man.—Tenders will be received by C. McCorquodale, secretary-treasurer, Morden, Man., until noon, July 23rd, for the construction of reinforced concrete bridge over Dead Horse Creek, on Thornhill Ave. Plans, specifications, tender form and other information may be obtained from the secretary-treasurer, or at the office of the highway commissioner, Parliament Buildings, Winnipeg.

Newmarket, Ont.—Tenders will soon be called for new bridges on Lydia, Prospect and Queen Sts.

Niagara Falls, Ont.—Tenders will be received by city engineer, D. T. Black, until August 4th, for construction of sidewalks.

Niagara Falls, Ont.—Tenders will be received until July 21st for concrete pavements, curb and gutter. W. J. Seymour, clerk. (Official advertisement in this issue.)

Orillia, Ont.—A special grant of $7,500 has been voted by the Simcoe county council for road between Midland and Penetanguishene. This amount will be in addition to $1,000 voted a year ago for this road, besides $1,000 from the townships of Tiny and Tay, and the towns of Penetang and Midland.

Ottawa, Ont.—Tenders will be received by the superintendent, department of Indian Affairs, until noon July 21st, for bridge work. Plans, etc., may be seen at the department

COUNTY OF YORK

TENDERS FOR BRIDGE CONSTRUCTION

Sealed tenders, plainly marked as to the contents, will be received by the undersigned up to 12 o'clock **noon** of **Monday, July 28th, 1919,** for the construction of:—

(1) A reinforced concrete bridge on the town line of East and North Gwillimbury.

(2) A reinforced concrete bridge on the town line of Whitchurch, East Gwillimbury.

(2) A concrete abutment at the Baldwin Bridge, all in the County of York.

Plans and specifications may be seen at the office of the undersigned, 40 Jarvis Street, Toronto.

The lowest or any tender will not necessarily be accepted.

FRANK BARBER,
County Engineer.

Toronto, July 14th, 1919. 297

TOWNSHIP OF YORK

CONSTRUCTION OF WATER MAINS

Sealed tenders, plainly marked as to the contents, will be received by the undersigned engineer for the Municipal Corporation of the Township of York up to 10 o'clock a.m., Tuesday, August 5th, 1919, for the construction of 6-inch cast-iron water mains in the following streets in the Township of York:—

1. Atlas Ave. North (1,124 ft.).
2. Hanson Road, Rockvale Ave., Clovelly Ave., Strader Ave. (2,840 ft.).
3. Miller Ave., Northcliffe Blvd., Westmount Ave. (1,940 ft.).
4 Robina Ave., Cedric Ave., Holland Park Ave., Wilmington Ave. (4,460 ft.).
5. Tay Ave., Glanville Ave., Rushton Road, Durham Ave. (3,370 ft.).
6. Bernice Ave., Eileen Ave., Mildred Ave., Lyndon Ave, Elvin Ave., Scarlett Road (7,190 ft.).
7. Florence Cres., White Ave., Brooke Ave., Pritchard Ave., Jane St. (4,200 ft.).
8. Thornhill Ave., Priscilla Ave., Windermere Ave., Brookside Ave., Bradley Ave. (7,530 ft.).

Plans and specifications and all necessary information may be obtained at the office of the Engineer, Frank Barber, 40 Jarvis Street, Toronto.

The lowest or any tender will not necessarily be accepted.

FRANK BARBER,
Engineer.

Toronto, July 14th, 1919. 298

CONCRETE BRIDGES

Sealed tenders will be received by Mr. H. Roach, Reeve of Uxbridge Township, Goodwood, Ont., up to **6 p.m., Wednesday, July 23rd,** or at the letting at Brechin on Thursday, July 24th, at noon, for the construction of a 28-ft. concrete girder bridge, known as Scott Bridge, at Lot 1, Concession 5, Mara, for the counties of Ontario and Victoria, and for a 24-ft. bridge at Lot 8, Concession 2, Mara, for the Township of Mara. For plans, etc., apply to

BOWMAN & CONNOR,
301 31 Queen St. West, Toronto.

TENDERS FOR 20-INCH CAST IRON PIPES AND VALVES, ETC.

Tenders will be received, by registered post only, addressed to the Chairman of the Board of Control, City Hall, up to noon on Monday, July 28th, 1919, for the construction and delivery of 20-inch cast iron pipes and valves for St. Clair Avenue, from Keele Street westerly, and for laying of same.

Specifications and tender forms for the foregoing may be obtained upon application at the office of the Water Main Extension Section, Department of Works, Room 320, City Hall, Toronto. Envelopes containing tenders must be plainly marked on the outside as to contents. Conditions relating to tendering, as prescribed by City by-law, must be strictly complied with, or tenders may be declared informal. Tenderers shall submit with their tenders the name of two personal sureties, approved by the City Treasurer, or in lieu thereof, the bond of a guarantee company, approved as aforesaid. The lowest or any tender not necessarily accepted.

T. L. CHURCH, Mayor,
302 Chairman, Board of Control.

TENDER FOR SEWER

Sealed tenders, marked "Tender for Sewer," will be received by the undersigned until 5 p.m., Monday, July 21st, for the construction of approximately 7,200 lineal feet of 15-inch sewer. Forms of tender and all necessary information may be obtained at the office of the Town Engineer, Oshawa, Ontario.

The lowest or any tender will not necessarily be accepted.

W. G. WORDEN,
Town Engineer.

Oshawa, Ont., July 14th, 1919. 300

(See page 54 for other tenders called)

of Indian Affairs, Ottawa, Indian agent at Muncey, and at post offices, London and St. Thomas.

Peterboro', Ont.—Contract for the construction of the new Hunter Street bridge across the Otonabee River has been awarded upon a cost-plus basis to the Russell, Townsend Co. Toronto. Estimated cost, about $275,000. Work will commence at once, although the main arch will not be constructed until next summer.

Peterborough, Ont.—The county council has voted $150 to Harvey Tp., to improve North Buckhorn Rd., on condition that Harvey expend $150 and the department of highways $300. Havelock has been granted $150 to be expended on street improvement. The county will raise $14,000 by debentures for the construction and repairing of several bridges.

Point Grey, B.C.—It has been decided by the town council to repair Highbury St. Estimates of costs have been received as follows: Waterbound macadam, at $8,180; oil macadam, $8,625; tarvia, $13,170; and asphalt, $12,450. The council considered only oil macadam and asphalt.

Portage la Prairie, Man.—Arthur Macow, 600 Merchants Bank Building, Winnipeg, has been awarded contract for concrete bridge. Tender price, $6,253.

Portage la Prairie, Man.—Tenders will be received by D. McCowan, secretary-treasurer, Portage la Prairie, Man., until noon, July 19th, for the construction of reinforced concrete culverts. Plans, specifications, tender forms and other information may be obtained at the office of the secretary-treasurer, or at the office of the highway commissioner, Parliament Buildings, Winnipeg, Man.

Regina, Sask.—Contracts for steel and concrete bridges at Wynyard and Theodore have been awarded by the department of highways. There were four tenderers in each case and in connection with every contract the lowest tender was accepted. Following are the contracts: Bridge near Wynyard, W. Newman and Co., Winnipeg, at $3,526; two bridges near Theodore, Parsons Construction Co., Regina, at $3,865 and $4,235.

Regina, Sask.—Tenders will be received until noon, July 30th, by D. A. R. McCannel, acting city engineer, for construction of street pavement and spur track pavement. Official advertisement in this issue.

Rosser, Man.—No tenders were received by the municipal council for excavating hauling and spreading gravel on C.P.R. road. The matter is for the time in abeyance. W. H. Beachell, secretary-treasurer.

Sarnia, Ont.—Tenders will be received by John A. Baird, city engineer, Sarnia, until noon, July 18th, for the construction of concrete curb and gutter. Plans, specifications, etc., may be seen at the office of the city engineer, city hall, Sarnia.

Sarnia, Ont.—The Warren Bituminous Paving Co. have been awarded contract by city council for resurfacing. J. A. Baird, city engineer.

Sherbrooke, Que.—Paving work to be undertaken by the street railway company, as well as work on the West Ward extension, will proceed immediately.

Sherbrooke, Que.—The Loomis-Dakin Co. has been awarded contract for paving in market square. Tender price, $2.54 per sq. yd.

St. Adolphe, Man.—Contract for two miles of road work has been awarded to J. Berriault, St. Adolphe, at $1,200.

ASSISTANT ENGINEER WANTED

Applications addressed to the undersigned will be received until 5 p.m., Monday, July 21st, for the position of assistant Engineer.

Applicants must be experienced in concrete road construction.

W. G. WORDEN,
Town Engineer.

Oshawa, Ont., July 14th, 1919. 299

St. Mary's, Ont.—The cement abutments for the Queen St. overhead bridge have been completed, but the floor girders have not arrived and the work is at a standstill. The cement approach to the station has also been commenced.

St. Rose, Que.—Contract for construction of road has been awarded by the municipal council to O'Connors, Ltd., 204 St. James St., Montreal.

Toronto, Ont.—Construction of brick block pavements and asphalt pavements on two sections of St. Clair Ave., with concrete curbs and gutters, has been recommended by the commissioner of works. Also asphalt pavements on Logan Ave. Total estimated cost, $102,077.

Toronto, Ont.—Tenders will be received by W. A. McLean, deputy minister of highways, until July 30th for concrete structures on provincial highway. (Official advertisement in this issue.)

Toronto, Ont.—The commissioner of works has recommended construction of pavements on Herman Ave., Kenilworth Ave., Oakvale Ave. Estimated cost, $36,799. Also concrete sidewalks on King St. W., McGregor Ave., Silver Ave., Cherokee Ave. Probable cost, $6,738.

Toronto, Ont.—The cost of extending Fairmount Crescent is estimated at about $7,000.

Trail, B.C.—By-laws have been passed authorizing improvements to several streets at a cost of $9,872, and for rock grading costing about $13,100. Also for construction of concrete bridge at a cost of $1,657.

Vancouver, B.C.—Negotiations are proceeding between the department of public works and the municipality and city of North Vancouver in connection with resurfacing 2½ miles of the Marine Drive.

Victoria, B.C.—By-law will be voted on this week for $300,000 for erection of Johnson St. bridge.

Victoria, B.C.—Contract for paving stretch of road between Craigflower bridge and Parsons bridge has been awarded to Palmer Brothers, Vancouver. Tender price, $75,000.

Victoria, B.C.—Improvements are to be made to the River Rd., from New Westminster to Burnaby boundary by the application of a thick coat of oil. Negotiations are similarly proceeding with the municipality of Chilliwack for the hard-surfacing of the main provincial road.

Victoria, B.C.—Some hard surfacing will be effected on Lulu Island. Two or three miles of road are involved.

Wallaceburg, Ont.—Tenders received by the town council for pavements were considered too high. It is proposed to do the work by day labor. C. B. Jackson, town clerk.

Wapella, Sask.—John Grainger, Brandon, Man., has been awarded contract for cement sidewalks. Tender price, 17 cents per sq. ft. for sidewalks and 25 cents per sq. ft. for crossings.

Windsor, Ont.—By-law will soon be submitted to ratepayers to authorize expenditure of $20,000 for two motor driven street flushers at $10,000 each. Also for $100,000 for sidewalks.

Welland, Ont.—Tenders for the construction of either water-bound macadam or bituminous penetration paving on broken stone foundation in the townships of Humberstone and Wainfleet, a distance of about ten miles, and also for ½ mile of concrete pavement or tar penetration surface road on Ridge Road, in the village of Ridgeway, will be received until noon, July 21st, by Robert Cooper, county clerk, court house, Welland. Tenders will also be received for the construction of a water-bound macadam road, 9 feet wide, approximately 2½ miles long, being the balance of road division 16, running south in the township of Humberstone. Plans and specifications can be seen at the office of the county clerk, or at the office of George Ross, county engineer, Welland.

Welland, Ont.—It is reported that the Federal government has provided for the appropriation of $40,000 to build the canal road, the feeder road and that piece of government

Tarvia

Preserves Roads~Prevents Dust

Applying "Tarvia-X" on Kennedy Road, Scarboro Township, Ont. Toronto and York Roads Commission.

The view in the circle is the finished road. Note smooth, dustless surface.

Has Your Town a *Good Roads Program?*

Every town, no matter how small, ought to have a definite road program.

Every county ought also to have one.

Roads should not be built in a patch-work, haphazard fashion, for the only result of such a policy is stretches of good roads interspersed with stretches of bad roads.

As a chain is no stronger than its weakest link, so a road is only as passable as its poorest parts.

Therefore, alternating *good* and *bad* roads are a costly abomination to all who travel over them and all who pay taxes for their construction and maintenance.

Our Service Department has persuaded many towns to work out a systematic road policy ; because we have been able to demonstrate that *great sums of money can be saved* by so doing.

A system of Tarviated macadam—that is to say, macadam that has been bonded with Tarvia to preserve the surface and make it automobile-proof—is an almost indispensable part of every Good-Roads Program today.

Tarvia roads are not only low in their first cost, but exceedingly low in maintenance cost.

Once a town or county adopts the policy of building Tarvia roads it rarely goes backward, but the mileage is increased from year to year.

There are several grades of Tarvia and a dozen methods of using the product.

If you are at all interested we should be glad to mail you an illustrated booklet showing Tarvia roads all over the country that are giving the maximum service and satisfaction at a minimum cost.

Special Service Department

This company has a corps of trained engineers and chemists who have given years of study to modern road problems. The advice of these men may be had for the asking by any one interested. If you will write to the nearest office regarding road problems and conditions in your vicinity, the matter will be given prompt attention.

The Barrett Company LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER

ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

highway between Quaker road and Port Robinson. Work has already commenced on the first two mentioned.

Welland, Ont.—The material for concrete road, from Welland to Port Colborne, has been delivered and work will be commenced at once.

WATER, SEWAGE AND REFUSE

Belleville, Ont.—Debentures will be issued to the amount of $32,871.06 for construction of sewers on several streets. Wilfred Holmes, city clerk.

Bowmanville, Ont.—By-law has been passed authorizing construction of sewer and water works on Duke St.

Burlington, Ont.—Tenders will be received by J. S. Allen, town clerk, until July 25th, for construction of sanitary sewers. Official advertisement in this issue.

Chatham, Ont.—J. W. Teweskbury, Chatham, has been awarded contract for four bridges over Rankin Creek and Cadotte Drains.

Dundas, Ont.—Tenderers for sewers will be invited to tender again on a cost plus fixed profit basis, upon recommendation of the engineer. It was thought by the engineer that the tenders of F. F. Fry and, A. R. C. Smith, which were both about $100,000, were too low, and that the work could not be done for that price.

Dundas, Ont.—The Francis Hinck Co. have been awarded contract for sprinkler equipment by the town council. Ten-per price, $6,888.30.

Dundas, Ont.—The town council has awarded contract for iron pipe to the Gartshore, Thompson Co. Tender price, $2,445.40. Tender of Smart, Turner Co. was accepted for pump, at $2,669. Contract for tile under 30 inches was awarded to the Toronto and Hamilton Sewer Pipe Co., for $23,866.84.

Kenora, Ont.—The town council did not accept any of the tenders for sewers to be constructed in the south ward, and have abandoned the project for this year.

Kingston (Sydenham), Ont.—The department of public works has awarded contract for sewage system and disposal works at convalescent hospital, to W. H. Harvey, Kingston, Ont.

Kitchener, Ont.—The city council plans new water supply and increased fire protection. Estimates of cost of necessary improvements range from $250,000 to $1,000,000. Consulting engineer, Hodgins, Buffalo.

Metcalfe, Ont.—Contract for drainage work on the Grey Creek has been awarded to D. B. Cameron, Berwick, Ont. Tender prices, earth excavation, 30 cents; hard pan, $1.22; rock, $3.25; price per acre for clearing, $50; price per lineal foot for grubbing, 60 cents.

Metcalfe, Ont.—No tenders were received by the town council for Dalglish drain. F. Iveson, clerk.

Newmarket, Ont.—The town council has decided to lay water mains on several streets. P. J. Anderson, clerk.

Orillia, Ont.—The town council contemplates extension of 8-inch water mains on James St., at a cost of about $1,762.05.

Owen Sound, Ont.—Work has been started on new filtration bed at the water works hill. Contractor, John Woolrich.

Shawinigan Falls, Que.—The municipal council has awarded contract for clay pipe sewers, to Edmond Bourassa, Notre Dame St., Three Rivers.

St. Honore, Que.—Plans are being prepared for water works system for the municipal council.

Stratford, Ont.—Tenders will be received by J. D. Fisher, township clerk, R.R. No. 1, Stratford, until noon, July 23rd, for the construction of the McTavish drain in the townships of North and South Easthope. Plans, specifications, etc., can be seen at the clerk's office, Amuhie, or at the office of Jno. Roger, O.L.S., Mitchell.

Three Rivers, Que.—Conroy Bros., 291 Centre St., Montreal, have been awarded plumbing contract for the Protestant School.

Toronto, Ont.—The council of the township of York intends to construct 6-inch cast-iron water mains for service pipes, together with all specials, valves and hydrants, on Right of Way, Hanson Rd., Rockvale Ave., Clovelly Ave., Strader Ave., Miller Ave., Northcliffe Blvd., Westmount Ave., Robina Ave., Cedric Ave., Holland Park Ave., Wilmington Ave., Tay Ave., Glanville Ave., Rushton Rd., Durham Ave., Bernice Cres., Eileen, Mildred, Lyndon and Elvin Avenues, Scarlett Rd., Florence Cres., White, Brook and Pritchard Avenues, Jane St., Thornhill, Priscilla, Windermere, Brookside and Bradley Avenues. Total estimated cost, $129,820.

Windsor, Ont.—By-law will soon be submitted to ratepayers to authorize an expenditure of $15,000 for new fire pump.

Woodslee, Ont.—Contract for improvements to Pipe Creek Drain has been awarded to The Windsor Dredging Co. Tender price, $8,150.

LIGHT, HEAT AND POWER

Creston, B.C.—Extension of electric service to this point is contemplated by the East Kootenay Light and Power Co.

Espanola, Ont.—Contract for installing heating and plumbing systems in school has been awarded to the Cochrane Hardware Co., Sudbury. Tender price, $9,000. Other tenders received as follows: Mitchell and Cooper, Sault Ste. Marie, $13,569; Dominion Plumbing Co., Fort William, $11,-682; Kutchaw Plumbing Co., Sudbury, $11,034; Purdy-Mansell Co., Toronto, $10,692; T. E. Regan, Toronto, $10,350; P. Morrison, Sudbury, $10,285.

Kamloops, B.C.—Development of hydro-electric power at Shuswap Falls on the Adams River is proposed.

Lac du Bonnet, Man.—The Winnipeg River Power Co. has started constructing a large power plant at Lac du Bonnet Falls, on the Winnipeg River, 75 miles north-east of Winnipeg. The project, which will be completed in two years, will cost between $6,000,000 and $7,000,000.

Norwood, Ont.—Negotiations are under way for a right-of way along the C.P.R. track, 15 ft. wide, from Norwood to Peterborough, upon which to build the new hydro-electric power line from Healy Falls.

Outremont, Que.—The city council contemplates extensions to electric light system, with underground conduits, cables, etc. Estimated cost, about $40,500.

Parry Sound, Ont.—The Boving Hydraulic and Engineering Co. have been awarded the contract for hydraulic equipment by the town council. Tender price, $19,270. Other two tenders were from the Morgan-Smith Co., York, Pa., for $24,268 and from the Wm. Hamilton Co., Peterborough, for $22,570.

Peterborough, Ont.—An electric radial from Peterborough to Kinmount is contemplated by the hydro-electric commission. Engineers will survey the route of the territory through which the proposed line is to be built this week.

Port Elgin, Ont.—Engineers of the Ontario Hydro-Electric Commission have prepared plans for power development in the municipalities of Huron and Bruce. It is said that with the Sangueen development scheme and with that at Eugenia, 10,000 h.p. will be available.

Toronto, Ont.—A. Welch and Son, 304 Queen St. W., have been awarded contract for heating and plumbing for new theatre being erected by J. and J. J. Allen.

Toronto, Ont.—The Hydro-Electric Power Commission of Ontario has awarded contract for two 20,000 h.p. water turbines to the I. P. Morris Co., Philadelphia, Pa. These turbines will be used for the Nipigon development. Contract for the generators for same has been awarded to the Canadian Westinghouse Co., Ltd., Hamilton.

Woodbine Heights, York Township, Ont.—Woodbine Heights ratepayers have requested that a hydro-electric lighting system be installed at once. W. Miller, chairman, ratepayers' association.

RAILWAYS

Brantford, Ont.—Extension to street railway is planned by city council. T. H. Jones, engineer.

Lindsay, Ont.—The town council has sent in a petition to bave the radial line extended to this city.

Puslinch, Ont.—Officials of the C.P.R. and G.R.R. have made investigations regarding a proposal to extend the street railway, from Guelph to Puslinch, skirting the lake to Hespeler or Galt, to connect either with the Grand River Electric Ry, or with the Lake Erie and Northern Ry. The city of Guelph recently obtained a charter for an extension of the Guelph Radial to Puslinch Lake and Hespeler.

Toronto, Ont.—It has been decided by the board of works to straighten the northerly curve of the street railway tracks on Broadview Ave., at a cost of $8,231.

FACTORIES AND LARGE BUILDINGS

Alvinston, Ont.—Shultz Bros., Brantford, have the contract for bank building for Merchants Bank of Canada, Montreal.

Arnprior, Ont.—It is the intention of the town council to remodel public school at a cost of $18,000.

Clinton, Ont.—$12,000 will be expended on erection of addition to public building.

Denman Island, B.C.—Tenders will be received by the minister of public works, until noon, July 22nd, for erection of addition to school at Denman Island, in the Comox Electoral District, B.C. Plans and specifications can be seen at the offices of the government agent, Cumberland and Vancouver, and the department of public works, Victoria, B.C. A. E. Foreman, engineer, public works department, Victoria, B.C.

Edmonton, Alta.—Separate tenders on general contract, electric wiring, plumbing, heating, ventilation and farm buildings for agricultural schools at Raymond, Youngstown and Gleichen will be received until July 24th, by L. C. Charlesworth, deputy minister of public works, Edmonton.

Esquimalt, B.C.—The military hospital project, for which $200,000 had been appropriated, has been abandoned by the department of public works.

Ford City, Ont.—R. Westcott and Co., Board of Trade Building, Windsor, has been awarded contract for warehouse, garage, storage tanks and pump-house for Imperial Oil Co., Ltd., 56 Church St., Toronto. Tender price, $28,000.

Fort William, Ont.—By-law will soon be submitted to citizens to raise $75,000 as a nucleus for a larger sum of $250,000 for the purpose of erecting a memorial hall. N. M. Paterson, interested.

Fredericton, N.B.—The directors of the exhibition have decided not to accept any of the four tenders which were received for construction of new transportation building. Arrangements have been made by which the construction of the building will be commenced immediately, with Ald. Judson Barker as superintendent, on a cost plan basis, the plans calling for its completion by August 25th. Estimated cost, $8,000.

Galt, Ont.—Drill hall costing about $13,000 will be erected here.

Guelph, Ont.—Endeavours will be made to secure a technical school in this city.

Guelph, Ont.—Tenders will be received until July 21st, by H. F. McNaughten, secretary, department of public works, Toronto, Ontario, for extension to Macdonald Hall (excepting, heating, lighting and plumbing) and for a piggery, both to be erected on the grounds of the Ontario Agricultural College. Plans and specifications can be seen at the Bursar's office, agricultural college, and at the department of public works, Toronto.

Hamilton, Ont.—Site has been secured on Ottawa St. for new branch library building.

Huntingdon, Que.—The Dominion Bridge Co. have contract for steel work in connection with erection of school.

Huntingdon, Que.—The Merchants Bank of Canada has awarded a contract for bank building to A. F. Byers & Co., 340 University St., Montreal. Tender price, about $20,000.

Kitchener, Ont.—The Canadian Consolidated Rubber Co., Ltd., has decided to expend $1,000,000 on erection of addition to tire plant.

London, Ont.—A joint post-office and custom house will be erected here at a cost of $400,000.

London, Ont.—The Holeproof Hosiery Co. of Canada, Ltd., has awarded contract for factory to Stone and Webster, 147 Oak St., Boston. Tender price, $250,000.

Mayfair, Sask.—Tenders will be received by R. G. Blackwood, architect, for erection of 12-room school for the public school board of Saskatoon.

Moncton, N.B.—The Can. Nat. Rys. has awarded contracts for section houses as follows: At Lapointe, Pecard, Bretagne, Lefebvre, Que., to A. J. Morin, Garthby, Que. At Grog Brook, N.B., to Israel Roy, Green Point, N.B. At Sirois, N.B., and one near Grog Brook, N.B., to Hamilton and Collier, Campbellton, N.B.

Moncton, N.B.—Contract for coaling plant at Sydney, N.S., has been awarded by Can. Nat. Rys. to Williams and Wilson, Ltd., Montreal.

Montreal, Que.—Tenders will be received by Audet and Charbonneau, architects, 194 Parc G. Etienne Cartier, Montreal, until noon, July 21st, for the construction of church and presbytery on Cote St. Antoine Rd., Notre Dame de Grace. Plans and specifications can be obtained on application to the architects.

Montreal, Que.—The Grand Trunk Ry., McGill St., plans erection of additional storage warehouse.

Preston, Ont.—The Bank of Toronto has decided to erect a new bank building on the corner of King and Wellington Sts. at a cost of about $60,000. Plans and specifications have been prepared.

Quebec, Que.—E. Cormier, New Birks Building, Montreal, is the architect for the new $500,000 factory to be erected for the Marceau Oil Cloth Co.

Regina, Sask.—Plans for the war memorial museum to be erected by the provincial government in the legislative grounds have been received from the architects who were invited to compete, and will be sent on by the department of pubic works to Dr. Ramsay Traquair, professor of architecture at McGill University, and Stephen Warrick, Montreal, the assessors. Under the terms of the contest the successful architect must be announced within twenty-one days of the closing of the competition. Those who are invited to compete are as follows: Brown and Vallance, Montreal; Emil Delay, Regina; E. and W. S. Maxwell, Montreal; Nobles and Hyde, Montreal; J. H. G. Russel, Winnipeg; Storey and Van Egmond, Regina; R. G. Bunyard, Moose Jaw; and David Webster, Saskatoon.

Sault Ste. Marie, Ont.—The extension of the rail mill of the Algoma Steel Co.'s plant, which was announced several weeks ago, and which will cost several hundred thousand dollars, is but the beginning of an extensive development of the plant, it is stated. The whole plan laid out by the officials of the company involves an expenditure of from five to seven million dollars, and includes the production of structural steel shapes of all kinds and sizes.

Three Rivers, Que.—MacDuff and Lemieux are the architects for creamery to be erected on St. George St. Estimated cost, $10,000.

Three Rivers, Que.—The Phœnix Bridge and Iron Works, Ltd., Montreal, have been awarded contract for technical school. Tender price, about $150,000.

Toronto, Ont.—J. and J. J. Allen have awarded steel contract for theatre on Waverly Rd. to Canadian Allis-Chalmers, Ltd.

Toronto, Ont.—Tenders will be received by Darling and Pearson, 2 Leader Lane, Toronto, until July 28th, either in bulk or for separate trades for all work required in the erection of a building for the electrical department of the University of Toronto, on ground adjoining the mining building.

THE "S.J.B." BOX

FOR SERIES ORNAMENTAL STREET LIGHTING SYSTEMS

¶ To provide a means of disconnecting lamps from circuits supplied with current by two-conductor cable, The Northern Electric Company have recently designed the "S.J.B." Box for use on series circuits operating at potentials of 7,000 volts or less.

¶ Figs. 1 and 2 show front and rear views of the box, and Fig. 3 shows how the box is installed in the pedestal of a lamp standard. This view was taken in Montreal where all of the standards used in connection with the new lighting system are equipped with these boxes.

¶ There are many interesting features in connection with this box, but the limited space at our disposal does not permit of a detailed explanation. To those interested, however, we will be glad to send photographs and full descriptive matter on application to our nearest branch house.

Windsor, Ont.—J. C. Pennington, Windsor, architect, has prepared plans for new factory for B. N. Marsh. Estimated cost, $30,000.

Windsor, Ont.—Plans have been prepared by A. H. McPhail, architect, for $1,000,000 worth of building including two schools and mausoleum.

Winnipeg, Man.—Building permits totalling $147,000 were issued on June 10th. They include: Imperial Bank, Arlington St., Fraser and McDonald, architects, $8,000; school house, Talbot Ave., $20,000; school house, Oak Ave., $20,000; brick warehouse, for Twin Separator Co., Whyte St., $21,000; tannery on Winnipeg Ave., $2,500; Bank of Hamilton alteration, Portage Ave., A. J. Bonnett, contractor, $7,500. A permit will soon be issued for the Jewish Orphanage building on Matheson Ave., for $60,000, to be built by the Sutherland Construction Co.

Winnipeg, Man.—Tenders will be received by C. J. Brown, city clerk, Winnipeg, until 3 o'clock, July 28th, for the supply of all labor and materials required for the erection of a two-story and basement garage building for the city light and power department. Instructions to bidders, plans and specifications and form of tender may be obtained at the office of J. J. Chisholm and Son, architects, 703 Great West Permanent Building.

MISCELLANEOUS

Collingwood, Ont.—Reconstruction of breakwater will cost $50,000.

Edmonton, Alta.—The municipal council contemplates an expenditure of $260,000 on further extensions and additions to municipal telephone system. Chas. Ed. K. Cox, city clerk.

Fredericton, N.B.—The New Brunswick Telephone Co. plans improvements and extensions to system at a cost of about $175,000.

Grosse Isle, Que.—Tenders will be received until noon, August 5th, by R. C. Desrochers, secretary, department of public works, Ottawa, for the construction of an extension to the eastern wharf at Grosse Isle Quarantine Station, County of Montmagny, Que. Plans and forms of contract can be seen and specification and forms of tender obtained at the department of public works; at the offices of the district engineers at Montmagny, Que.; post-office building, Quebec, Que., and Shaughnessy Building, Montreal, Que.

Ha! Ha! Bay, Que.—The J. T. White Engineering Co., New York, have been awarded contract for concrete wharf. Tender price, $400,000.

Hamilton, Ont.—Tenders will soon be called for harbor improvements, to cost $100,000.

Kamloops, B.C.—The Kamloops Copper Co. contemplates diversion of water from Iron Mask Lake, the water to be used for milling and concentrating purposes at the mine. A Wallinder, agent.

Kenora, Ont.—A new wharf at Rideout Bay, on the Winnipeg River, will be constructed by the Federal Government. Estimated cost, $4,000.

Nanaimo, B.C.—Tenders will be received by R. C. Desrochers, secretary, department of public works, Ottawa, until noon, Friday, July 25th, for the construction of repairs to wharf at Sydney, repairs to floor and approach at Roberts Bay and repairs to wharf at Saanichton. Plans and forms of contract can be seen and specification and forms of tender obtained at the department of public works, at the office of the district engineer, Victoria, B.C., at the post-offices, Vancouver, B.C., Sydney, B.C., and Turgoose, B.C.

Okanagan Centre, B.C.—Tenders will be received until noon, August 5th, by R. C. Desrochers, secretary, department of public works, Ottawa, for construction of wharf. Plans and specifications may be seen at the office of the district engineer and at post-office, Okanagan Centre.

Ottawa, Ont.—Contract for dredges P.W.D. No. 110 and P.W.D. No. 116 has been awarded by the department of public works to M. Beatty and Sons, Ltd., Midland, Ont.

Plunkett, Sask.—The Plunkett Rural Telephone Co. will receive tenders until July 21st for the construction of extensions of systems. Plans and specifications are on file at the department of telephones, Regina, or at the office of the secretary of the company. J. H. F. Armitage, secretary-treasurer, Plunkett, Sask.

Port Maitland, Ont.—$200,000 will be expended by the department of public works for erecting portion of east pier.

Prince Rupert, B.C.—George B. Hull, resident engineer for the Federal Government, has been notified that appropriations have been made for a survey of Skidegate Narrows, Metlakatla Bar and the fishermen's wharf at Seal Cove. Plans have also been received from Ottawa for public float to be constructed at Port Essington.

Spry Bay, N.S.—The department of public works has awarded contract for extension to wharf to A. W. Girroir and W. F. MacKinnon, Antigonish, N.S.

St. Gregor, Sask.—Tenders will be received by Thos. Coughlan, secretary-treasurer, St. Gregor Rural Telephone Co., Ltd., until July 25th for extensions to system. Plans may be seen at the department of telephones, Regina.

St. Ignace de Loyola (Nord), Que.—Onésima Poliquin, Portneuf, Que., has been awarded the contract for reconstruction of wharf and approach by the department of public works.

Three Rivers, Que.—Tenders will be received until noon, July 24th, by R. C. Desrochers, secretary, department of public works, Ottawa, for dredging channel and basin in the eastern outlet of the River St. Maurice. Combined specifications and forms of tender can be obtained on application to the secretary, department of public works.

Toronto, Ont.—It has been decided to expend about $125,000 for improvements and extensions to parks in the eastern section of the city. Appropriations have been made as follows: Ramsden Park, $15,000; Allan Gardens, $10,000; Riverdale, Withrow and Monarch parks will also be remodelled.

Toronto, Ont.—It has been proposed by Mayor Church to erect a pier in the lake at the exhibition grounds.

Vancouver, B.C.—Engineers are taking borings for the new C.P.R. pier which is to be constructed between piers "A" and "D." It is understood that the engineers are finding a good bottom for the location of the structure and that a solid foundation can be secured at a reasonable depth. The new pier will be of sufficient proportions to accommodate the largest liners.

Vancouver, Id., B.C.—Wharves will be reconstructed at Ladysmith, Sydney, South Gabriola, Port Renfrew and Fulford Harbor. Repairs will be made to wharves at Wakes Bay, Saanichton, Esquimalt, William Head and Robert's Bay.

Victoria, B.C.—Tenders will be received by the Land Settlement Board, until noon, July 21st, for the construction of a ditch through parts of district lots 7, 81 and 90, New Castle district, and part of district lot 1, Cameron district. Plans, specifications and approximate estimate of the work necessary to be performed may be seen at the office of the "Daily Herald," Nanaimo, B.C., at the office of "The Columbian," New Westminster, B.C., or at the office of the Land Settlement Board, Victoria, B.C.

Welland, Ont.—Contract for supply and delivery of sand required on the Welland Ship Canal has been awarded by the department of railways and canals to the National Sand and Material Co., Ltd., Welland, Ont.

Wilkie, Sask.—Contract for extension to Narrow Lake Rural Telephone system has been awarded to T. W. Brown, Saskatoon. Tender price, $8,690.

The Canadian Engineer

A Weekly Paper for Civil Engineers and Contractors

Point St. Charles Filtration Works, Montreal

Results of First Year's Operation—Output from Start Slightly Over Full Rated Capacity—Efficiencies During Last Nine Months from 96.2% to 99.1% Without Chlorination, and from 98.1% to 99.8% With Chlorination

DURING the twelve months ended June 30th, 1919, constituting the first year's operation, the Point St. Charles filtration works, Montreal, averaged 50.3 million gallons daily of filtered water. This is slightly more than the full rated capacity, the plant having been designed for a nominal daily output of 50 million gallons.

Montreal's requirements have grown to such an extent that the output of this municipally-owned plant was insufficient, despite the fact that thousands of consumers are supplied by another plant (owned by the Montreal Water & Power Co.); therefore an average of 12.8 million gallons of raw river water was added daily to the 50.3 million gallons of filtered water, and the mixture was effectively chlorinated.

The accompanying table gives the results of the daily chemical analyses, averaged for each month. July, 1918, was the first month after operation commenced for which complete data of all laboratory tests are available, the months of April, May and June, 1918, having been required for regulating the plant and correcting intake troubles due to frazil. In this first month of actually complete operation, with a raw water count of 530, the pre-filters showed 87.9% bacterial efficiency, and the final filters, 95.3%. The filtered water was mixed with 16.1 million gallons of raw water, and the mixture was chlorinated, the final bacteria count of the water as delivered to the mains showing 93.7% removal.

The bacteria-removal figures vary considerably until the end of September, 1918, at which time the plant appears to have been "tuned up" to an average condition or efficiency.

From October, 1918, to June, 1919, both months inclusive, the final filter bacterial efficiency ranged from a minimum of 96.2% in June, 1919, to a maximum of 99.1% in May, 1919. The bacteria-removal of the combined raw and filtered water (after chlorination) ranged, in the same period, from a minimum of 98.1% in October, 1918, to a maximum of 99.8% in April, 1919.

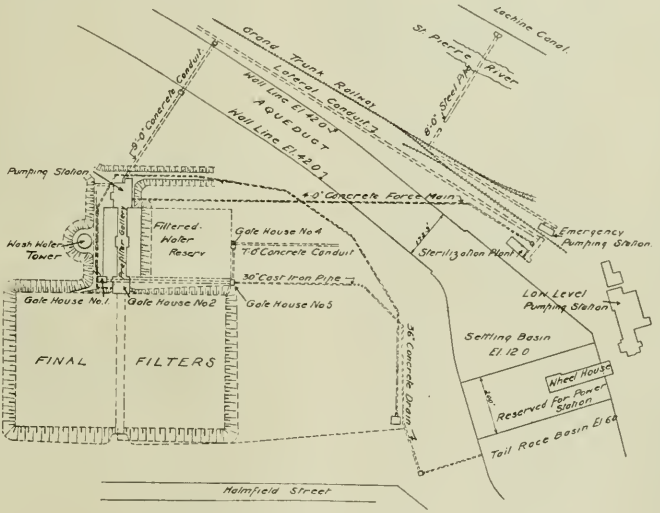

FIG. NO. 1—GENERAL PLAN OF FILTRATION WORKS

The plant has both a shore intake and a mid-stream intake situated about two miles above the Lachine Rapids of the St. Lawrence River. From an entrance gate chamber which receives the supply from both intakes, a concrete conduit, 8.5 ft. in diameter, formerly conveyed the water to the low level pumping station, from which it was pumped through the distributing mains to the city's reservoirs.

For many years the excessive number of cases of and deaths from typhoid fever had demonstrated to Montreal's citizens the necessity of improving the quality of the water used for domestic purposes. The increasing pollution of the water supply, due to the discharge of sewage and other impurities from towns within the drainage area above the intakes, is indicated by Fig. No. 8, which shows graphically the total number of deaths, and the death rate per 100,000 population, from typhoid fever for a long period of years.

During the late fall and winter of 1909-1910, a severe epidemic of typhoid fever prevailed in Montreal and its suburbs, and occasioned 203 deaths between October 1st, 1909, and March 1st, 1910. The necessity for prompt action was recognized by the city officials, and the chlorination of the municipal water supply was started February 8th, 1910, and has been regularly continued to the present time.

Hering & Fuller, consulting engineers, New York City, were instructed April 4th, 1910, to report on the best means of securing an improved water supply. These engineers submitted their report July 2nd, 1910, and recommended filtration of the St. Lawrence River water. Their recommendation was adopted and they were engaged to co-operate with the late Major Georges Janin, then city engineer, in preparing plans and specifications and in supervising the construction of the works.

A 9 ft. concrete conduit, connected to the 8.5 ft. main supply conduit previously mentioned as having supplied the low level station, brings the untreated St. Lawrence River water to the filtration pumping station. The purpose

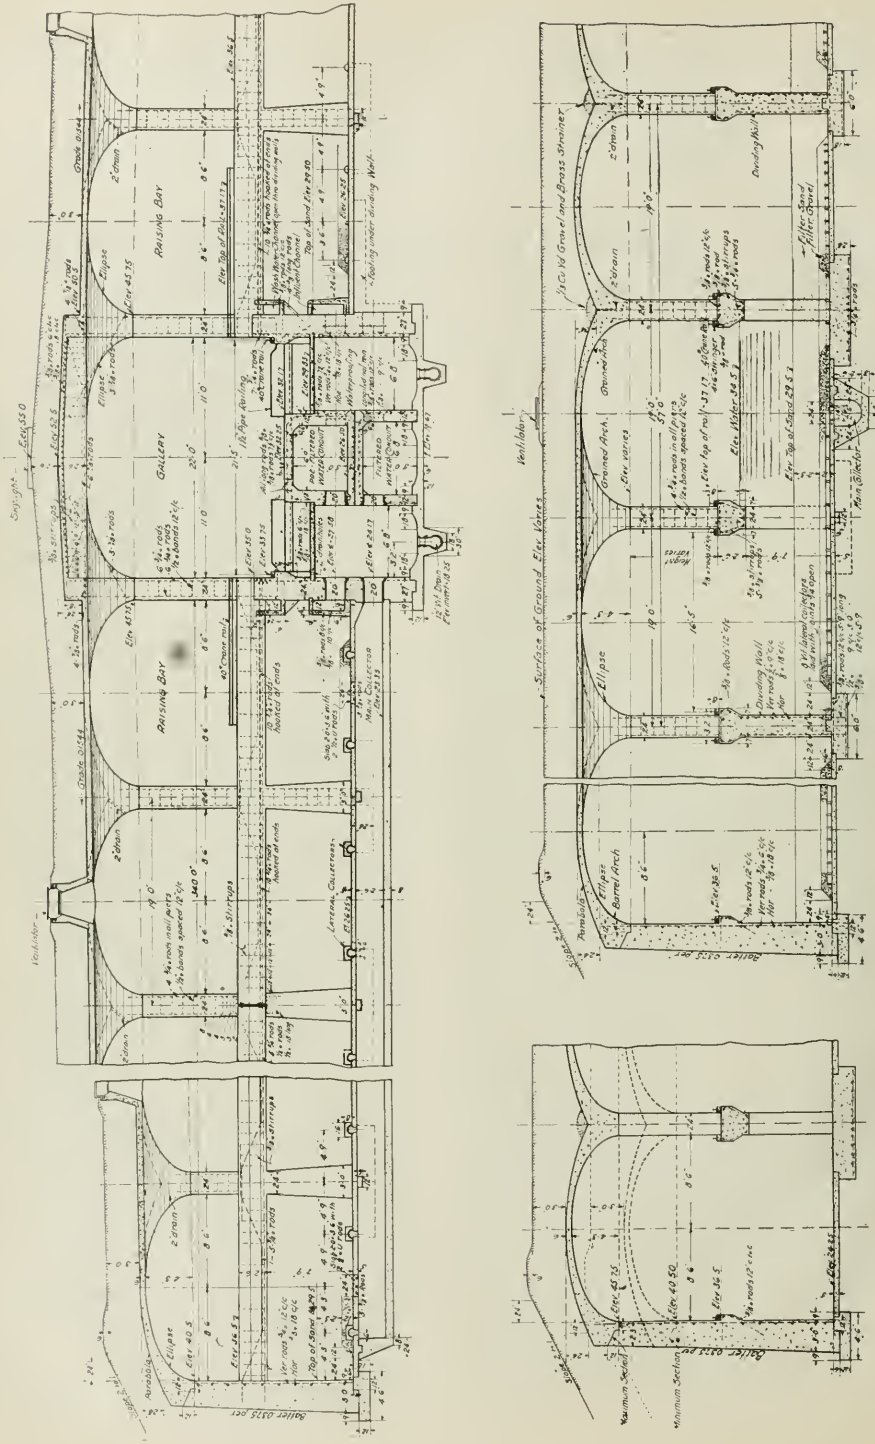

FIG. No. 2—SECTIONS THROUGH FINAL FILTERS, POINT ST. CHARLES FILTRATION WORKS, MONTREAL

of this pumping station is to lift the water to the prefilters, a height of approximately 18 ft., and to furnish water at a higher pressure for washing the prefilters at times of cleaning.

From the prefilters, or rapid filters, which form the first step in the purification process, the water flows by gravity to the final filters, which are quite similar in construction to slow sand filters. Passing through the final filters, the water flows into the filtered water reservoir, and is subsequently chlorinated.

From the filtered water reservoir, the water flows to the filtration pumping station, from which it is pumped to the low level pumping station, where it is forced by high pressure pumps through the distributing mains and to the city's reservoirs.

Should the proposed aqueduct enlargement work be completed, the filtered water will not return to the filtration pumping station but instead will flow by gravity from the filtered water reservoir to a new hydro-electric pumping station at the end of the aqueduct, and from that point will be delivered to the mains.

The filtration pumping station is a two-story structure about 80 ft. by 60 ft. The lower story is below the ground level and is traversed by the raw-water suction conduit and the raw-water discharge conduit, which are placed one upon the other. The direct-connected, motor-driven centrifugal pumps are arranged on either side of the central conduits in such manner as to obtain their supply from the lower, or suction conduit, and deliver into the upper or discharge conduit with a minimum of piping connections. Four of the pumps on the north side of the station are also similarly connected to a filtered-water suction conduit and a filtered-water discharge conduit, and provided with suitable check and controlling valves, equipped with standard hydraulic cylinders. This permits of one or all of these pumps on the north side of the station to be used for delivering filtered water to the low level pumping station. Should a new hydro-electric pumping station be completed, and the filtered water flow to it by gravity, all raw water pumps in the filtration pumping station will be available for supplying the filters.

The pumping station includes the following units:—

4	Raw water pumps	17,500 Imp. gals. per min.
2	Raw water pumps	11,600 Imp. gals. per min.
2	Raw water pumps	5,800 Imp. gals. per min.
2	Wash water pumps	1,300 Imp. gals. per min.
1	Sump water pump	330 Imp. gals. per min.
1	Sump water pump	150 Imp. gals. per min.
1	Three-inch hydraulic pressure pump	90 lbs. pressure.
1	Rotary blower	5,000 cu. ft. air per min.

All of these pumps, with the exception of the 3-in. hydraulic pressure unit, were installed under the original contracts. The 3-in. pump was installed for emergencies, to keep the pressure in the new hydraulic system uniformly 90 lbs.

The blower and the wash water pumps are used in cleaning the pre-filters. The sump pumps remove seepage and drainage water. The six largest pumps and the blower are operated by motors using 2,200-volt alternating current. The other pumps operate under 550-volt current.

The upper story of the pumping station is above the ground level and, similar to all other buildings of the plant, has red brick walls and cinder concrete roofs covered with green tile. The north side of this upper story contains the chemical laboratory. The south side contains rooms for storage, etc.

The pre-filters, located east of and adjoining the pumping station, and supported by groined arches above the roof of the filtered water reservoir, are sixteen in number, each having a net filtering area of 1,200 sq. ft., arranged eight on each side of a central operating gallery. Each pre-filter is divided longitudinally by a central gutter into which empty the sixteen lateral reinforced concrete wash water gutters. The strainer and air system is made up of cast iron headers and 2-in. cast iron laterals, with brass strainers spaced at 6-in. centres. The filtering material consists of 15 ins. of gravel, graded into four sizes and placed in corresponding layers, and 30 ins. of filter sand. The details of a pre-filter unit is shown in Fig. No. 4.

Longitudinally through the centre of the operating gallery are two concrete conduits, placed one upon the other.

TABLE SHOWING PERFORMANCE DURING PAST YEAR OF POINT ST. CHARLES FILTRATION WORKS, MONTREAL

	Average Daily Consumption				Turbidity			Bacteria Count				Bacterial Efficiency—Per cent.		
1918	Filtered Water	Raw Water	Total	Chlorine Used P.P.M.	Raw Water	Pre-filtered Water	Finally Filtered Water	Raw Water	Prefiltered Water	Finally Filtered Water	Raw and Filtered Water Mixed—After Chlorination	Pre-filters	Prefilters and Final Filters	Filtration and Chlorination of Mixed Water

FIG. NO. 3—SECTION THROUGH FILTRATION PUMPING STATION AND PREFILTERS

The upper one is the raw water supply conduit from the filtration pumping station and the lower is the pre-filter effluent conduit leading to the final filters. These two conduits are connected to the pre-filters by cast-iron piping with hydraulic controlling valves. All these valves and also the valves for wash water, air and drainage are controlled from sixteen operating tables on the gallery floor, each table being located in front of its corresponding filter.

For controlling the rate of filtration, rate controllers of the "Earl" type are provided. These are so connected to a master controller that the discharge from the pre-filters is automatically adjusted to the discharge from the final filters, which in turn is similarly controlled automatically by

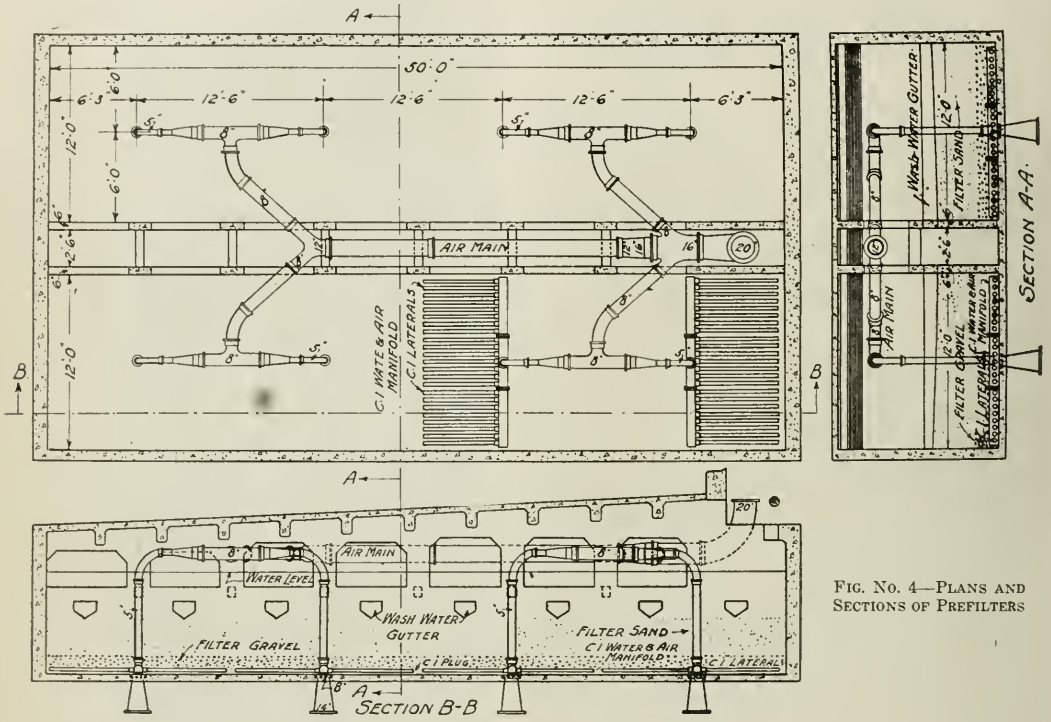

FIG. No. 4—PLANS AND SECTIONS OF PREFILTERS

the amount of water being drawn from the filtered water reservoir. In other words, the plant as a whole delivers filtered water at the same rate as it is used in the city, without manual operation of the many controlling valves.

The final filters are sixteen in number and, similarly to the pre-filters, are arranged eight on each side of the operating gallery. The filters are covered by groined arches supported by piers spaced at 19 ft. centres. The pier load is carried on foundation blocks independently of the rest of the floor, which is flat and but 5 ins. thick. The filters are each 55 by 340 ft., inside measurements, with the short dimension adjoining the gallery to accommodate the use of Blaisdell washing machines for the filter cleaning.

The underdrainage system consists of two half-round 8 in. tile laterals in each bay, which discharge into a central main collector, 2½ ft. in diameter, extending the entire length of the filter below the floor level. The filter material includes 12 ins. of graded gravel, placed in four layers, and 27 ins. of sand. The conduits and piping connections in the gallery, including the Earl rate controllers, are similar to those of the pre-filters.

The Blaisdell washing machines travel on tracks supported by the piers. They wash the upper layers of sand, leaving the sand bed clean and uniform, and pump away to the drains all dirt and other foreign matters which may have accumulated since the previous washing. All this is accomplished at one operation and by one operator. Among the advantages of this method of cleaning the filters, says Fred E. Field, assistant superintendent of water works of city of Montreal, are that the length of time the filter is out of service is a minimum, being from 6 to 8 hours only; the removal of the dirt from the sand is more complete than can be done by hand cleaning, as the cleaning process extends to any desired depth below the surface of the sand; the sand bed is left more uniform and without the compacting which accompanies walking over the sand by workmen; there is no break in the routine of the work during the winter and no decrease in the effective filtering area.

A heating and ventilating system is provided to prevent skim ice forming during the winter months and interfering with the free movement of the washing machines, and also to make the plant more healthful and comfortable for the workmen. This system consists of a fan and air ducts so arranged that heated air can be blown uniformly over the entire area of the filters. It was not found necessary, however, to use this system during the past winter.

The filtered water reservoir is of concrete, with groined arches for the roof and inverted groined arches for the floor. It is about 430 by 232 ft., and has a capacity of 6¼ million Imperial gallons. With the exception of its use to control the output of the plant, as has previously been described, there is nothing unusual in its design or method of operation. It was found necessary, however, in June, 1918, to place a bulkhead of stop-logs in gate-house No. 3, for its entire depth, to force the filtered water coming from the final filters through the east side of the reservoir, through a series of baffles, to the suctions of the pumps on the west side, thus eliminating the dead water which was found on the east side of the reservoir.

A butterfly valve was also placed on the filter effluent to prevent overflow of the filtered water reservoir into the pumping station. This valve can be closed rapidly but, in so doing, the final filters are disturbed. The usual practise, on occasion of power failure, if of more than five minutes' duration, is to close the sixteen filters by releasing each automatic valve. This, while not so rapid as the action of the butterfly valve, preserves the filter formations intact.

The filtration works uses electric current for power, heating and lighting. The city obtains current from the Montreal Light, Heat & Power Co., which has a 10,000-volt transmission line near the works. Branch connections from this transmission line bring 10,000-volt alternating current to the filtration transformer building, where it is reduced to 2,200 volts and then transmitted through an underground conduit system to the filtration buildings. Here it is used at 2,200 volts for the motors operating the main pumps or reduced by transformers to 550 and 220 volts for other machinery and for lighting and heating.

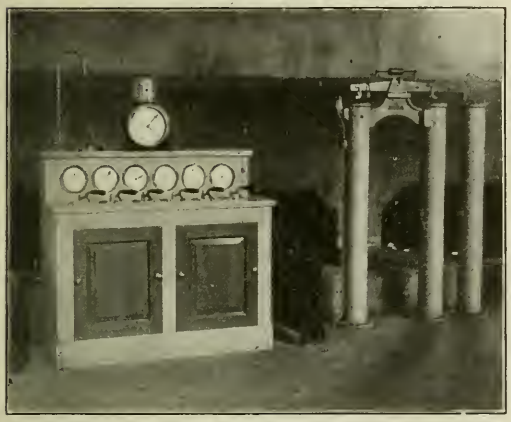

FIG. NO. 5—PREFILTER OPERATING TABLE AND AUTOMATIC CONTROLS

Heating throughout the entire works is accomplished by means of electric radiators.

The Blaisdell machines require direct current. Consequently a motor-generator set is provided to supply this current to the machine motors through the three miles of double trolley lines by which the machines are operated in the final filters.

The cost of the plant is given in the following table:—

FILTRATION CONTRACTS

	Cost
Pumping machinery, blower and cranes, British Electric Plant Co.	$ 40,250.00
Final filters and appurtenances, F. H. McGuigan, transferred to Norman M. McLeod	674,436.20
Prefilters and filtered water reservoir, F. H. McGuigan, transferred to Norman M. McLeod	498,782.30
Pumping station, wash-water tower and buildings, F. J. Jago Co.	160,076.00
Interior painting, Charles Larin	1,815.42
Exterior electrical conduit system, G. M. Gest.	6,069.80
Underground electrical cables and appurtenances, Northern Electric Co., Ltd.	12,627.04
Transformer building, city of Montreal	6,000.00
Total cost	$1,400,056.76

The operating tables, gauges, the strainer system and other filter equipment were supplied by the Roberts Filter Mfg. Co., of Darby, Philadelphia, Pa. The rate controllers were supplied by the Pittsburgh Filter & Engineering Co., of Pittsburgh and Oil City, Pa.

After practically all of the above contracts were completed, the operation of the plant was prevented by the lack of proper filter sand. The earlier contractors endeavored to obtain filter sand and gravel from numerous locations around Montreal Island, but they were all found

FIG. NO. 6—EXTERIOR VIEW, POINT ST. CHARLES FILTRATION WORKS, MONTREAL

to be unsuitable. A plant was finally erected under the design of W. B. Fuller, formerly of New York, and was located at Pierreville, near Lake St. Francis.

A suction dredge was used and the material was washed in tanks and then graded by passing through suitable revolving screens. The gravel was treated in similar manner. It was found that the available sand properly graded for the pre-filters ran about 50% of the quantity handled to obtain same. The sand for the final filters was found in different pockets, under water, practically graded to conform to specifications. This sand ran close to 100% of the quantity pumped.

The total quantity of sand required for the pre-filters, ranging from 0.40 to 0.50 mm. in diameter, was 2,000 cu.

FIG. NO. 7—PREFILTER GALLERY

yds.; that for the final filters, ranging from 0.25 to 0.35 mm. effective size, was 27,000 cu. yds. The total quantity of gravel for the pre-filters was 800 cu. yds.; the final filters required 8,000 cu. yds.

When the design of the Point St. Charles filtration works was started, the amount of water supplied by the municipality was about 37 million Imperial gallons daily. The filtration works were designed for a nominal capacity of 1½ times the requirements at that time. It was realized that extensions to the filters would be required in a few years, and the design allows for extensions with but little difficulty and without serious disturbance of the regular operation of the plant.

Annexations of adjoining municipalities, and the large extension of the city's water distribution system, have been more rapid than was expected. The new plant was required to work to full capacity from the day it was put into service and is now inadequate. The need for immediate action to provide for a much greater daily capacity of filtered water is so apparent that the city will undoubtedly

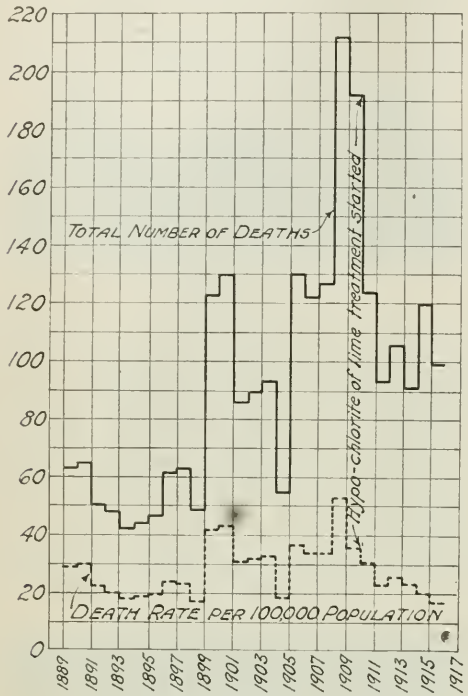

FIG. NO. 8—GRAPH SHOWING DEATHS FROM TYPHOID, 1889 TO 1917, CITY OF MONTREAL

in the near future let contracts for extension of the present works.

The original design contemplated the ultimate enlargement of the plant, it is said, along the following lines:—

Conversion of the final filters into slow sand beds,—capacity	30,000,000 gals.
Conversion of the pre-filters into mechanical filters,—capacity	40,000,000 gals.
Construction of two additional batteries of mechanical filters,—capacity	80,000,000 gals.
Total daily capacity	150,000,000 gals.

To carry out this scheme of extensions, it would be necessary to construct a new basin for coagulation, using alum as the coagulant, and also a new filtered water reservoir at a higher elevation than the present one, so that water could be delivered under greater head to the proposed new pumping station. The scheme contemplates the use of the existing reservoir as at present, but only to store filtered water from the proposed slow sand beds.

It is claimed that the proposed new pumping station could be built to advantage to the southeast of the site of the proposed power station, between Halmfield Street and the aqueduct excavation. This location would eliminate further congestion at the present low level pumping station and would allow for future extensions, it is said, to greater advantage than the present site.

The filtration works were constructed under the general supervision of Paul E. Mercier, engineer of public works, and T. W. Lesage, engineer-superintendent of water works. Frederick E. Field is the assistant superintendent of water works; A. B. Reid, electrical and mechanical engineer; Allan Kilpatrick, chief filter operator; and J. H. Harrington, chief chemist. To Messrs. Field, Kilpatrick, Reid and Harrington, *The Canadian Engineer* is indebted for all of the above information, drawings and photographs.

PREPARATION OF SPECIFICATIONS FOR CONCRETE

Practical and Advantageous to Specify Concrete According to Strength or Any Other Quality Desired—Some Specifications Result in Unknown Factors of Safety

BY I. F. MORRISON
Assistant Professor of Structural Engineering, University of Alberta

THE problem of proportioning concrete is the subject of extensive investigations in many laboratories at the present time, and several well-known investigators have arrived at reliable results which have quite well determined the sound principles to be followed in the making and mixing of concrete. In fact, sufficient data and information are already available to enable almost any contractor to make good concrete of a required strength in a certain time, and more is being rapidly added to the great mass already accumulated.

In the field these methods are being put into practice with success, resulting in a uniformity of product, a certainty of results, and consequent economy. In most offices, however, where designs are being carried out in both plain and reinforced concrete, this is not the case. The reason is this: Specifications for the quality of concrete are not kept up-to-date and many designers are still calling for 1:2½:5 mixes for 500 lbs. per sq. in. concrete; 1:2:4 mix for 650 lbs. per sq. in.; 1:1½:3 for 750 lbs. per sq. in., etc., these being the allowable stresses at, say, 28 days. The factor of safety is relied upon to cover the deficiencies.

Now a 1:2:4 mix may or may not make a concrete good for the usually assumed 2,000 lbs. per sq. in. at 28 days. That depends upon several factors, including the quality of cement, quality and grading of fine and coarse aggregates, quantity of water and methods of mixing and handling; and, to any engineer who may read this, upon several of his own pet ideas on the subject, even upon the effect of the change in declination of Polaris.

Nevertheless, the above-mentioned factors are the most important, and most contractors realize their importance. The control of the work on any large job now-a-days is such that attention is given to all of these matters.

The designer in the office, however, is still plodding along, calling for a 1:2:4 mix—which is so antiquated as to be almost meaningless—when he uses a stress of 650 lbs. per sq. in. in his design. The result is that one job, or a part of it, has a factor of safety of, say, about 2, and the next, or a part of the same one, has a factor of safety of about 6 or 7. This is certainly not economy; furthermore, if additions or extensions are to be made in the future, how is one to tell whether the original factor of safety was 2 or 7?

This article is essentially addressed to the designer and the one who writes specifications in the office. If they are to make use of the methods and valuable information already acquired for mixing good concrete which is suited to the purpose, they must co-operate with the engineer and contractor in the field. After plans and specifications leave the office, it is too late to change materially the entire design; the damage is already done. It may be possible for the field engineer to produce 2,000 lbs. per sq. in. concrete, but it may not be economical. On the other hand, a contractor would certainly be living up to the specifications if he put in 1:2:4 concrete, as called for, whether it gave 1,000 or 3,000 lbs. per sq. in. at 28 days.

Now for the constructive part of this criticism:—

Specifications should call for concrete of a certain strength. The strength called for should be varied to suit the various purposes to which the material will be put, and an appropriate factor of safety should be used in the design. Available materials in the locality of the proposed work should be sampled and tested by a competent engineer, and, in order to make use of the information, the designer should be informed, as early as possible, as to the strength available from these materials.

In almost any locality tests on 6 by 12-in. cylinders can easily be carried out. There usually is not time to do this after the contract is let, but some weeks are usually spent in preparing the layouts preliminary to the actual design of the work, and it is during this time that the proposed testing should be carried out.

Even if it be too late to carry out such tests, a contractor can succeed in making a concrete of any reasonable desired strength if the matter be left entirely in his hands. There is considerable information always available to enable him to accomplish the working out of the proper proportions, and he should be required to present his proposed proportions to the inspector sufficiently early to permit a careful checking of them.

Several years ago such a method as is herein suggested would have been open to several objections. These objections to-day are not well founded. The method of specifying concrete according to the strength, or any other quality desired, has not only become extremely practical, but is more advantageous from the standpoint of economy to all concerned.

PUBLICATIONS RECEIVED

SAND AND GRAVEL IN ONTARIO.—By A. Ledoux. Report to the Ontario Bureau of Mines, published by the King's Printer of Ontario, 138 pages and paper cover, 6½ by 9½ ins., illustrated. The report reviews the characteristic properties of sand and gravel and methods of testing, and deals with the origin and occurrence of fragmental rocks, and the distribution of sand and gravel in Ontario. The several counties have been arranged alphabetically and the location of every described deposit has been indicated by township, concession and lot. Deposits in more than forty different counties were visited during four months of field work. The author states that this report should be considered as only preliminary, as it is desirable to make a large number of tests of mortars and concretes made from the materials sampled, and also to secure further chemical analyses.

A new power project in Manitoba, known as the Winnipeg River Power Co., has been organized, and the $7,000,000 plant proposed will require three years for completion. The site of the development will be Bonnet Falls, 75 miles northeast of Winnipeg. This plant will have an ultimate capacity of 168,000 h.p., in six units of 28,000 h.p. each. This will exceed the combined output at present of the municipal plant at Point du Bois and that of the railway company at Pinawa Channel.

The Dominion Bureau of Statistics, Ottawa, has just issued a directory of the chemical industries in Canada, listing the names, addresses and products of nearly 500 Canadian firms manufacturing chemicals or other products in which the processes used are essentially dependent upon the agency of chemical change.

The Dominion Iron & Steel Co., Ltd., Sydney, N.S., have accepted an amendment to their government contract for steel plate. The original contract was for 50,000 tons per year for a period of 5 years, at $4.15 per hundred pounds. This has been modified by mutual agreement to $3.65 per hundred pounds. This means a saving of approximately $2,500,000 to the government. The company will now complete the erection of the new mill at an approximate cost of $5,000,000.

THE COST OF A MILE OF ROAD*

By George A. Duren
State Highway Engineer of Texas

THE three diagrams herewith present the elemental facts pertaining to the cost of a mile of road. Fig. 1 shows transportation costs for motor vehicles for various grades and surfaces. Fig. 2 is based on facts as set forth in Fig. 1, to show the annual cost of a mile of road, including cost of maintenance, cost of traffic for varying costs per ton mile, and interest on the cost of construction. Fig 3 shows the cost per ton mile, including the transportation cost per

ton mile paid by the user of the highway and the cost per ton mile of the highway itself, which is paid by the taxpayer in highway construction and maintenance.

All the highway authorities have been dealing with highway construction and maintenance almost solely in an effort to deal with this subject at the least possible cost on the part of the taxpayer, with little or no consideration for the cost of transportation.

The authorities agree that a 9-ft. gravel road is a satisfactory and economical highway for traffic not to exceed 200 vehicles per day, and that a 16-ft. gravel road is a satisfactory and enonomical highway for use of vehicles not to exceed 500 per day. Authorities differ concerning the automobile highway for traffic of from 500 to 1,000 vehicles per day, but the general opinion is that for this traffic some form of

*From a paper presented at an Engineering and Road Builders' Congress at Mineral Wells.

bituminous surface is most satisfactory. It is suggested that for traffic exceeding 500 vehicles per day and not exceeding 750 vehicles per day, a macadam road with bituminous surface treatment should be used; and for traffic exceeding 750 vehicles per day and not exceeding 1,000 vehicles per day, a substantially built asphalt macadam construction should be used. Traffic exceeding 1,000 vehicles per day

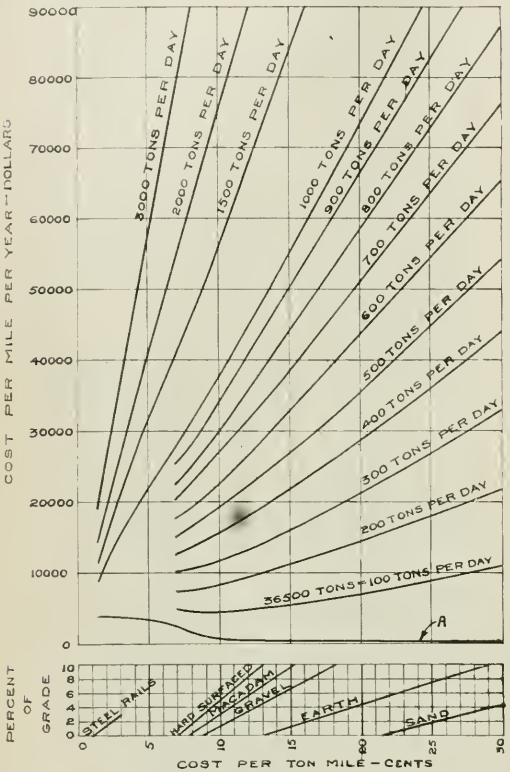

FIG. 2—ANNUAL COST OF A MILE OF ROAD, INCLUDING COST OF MAINTENANCE, COST OF TRAFFIC FOR VARIOUS SURFACES AND GRADES AND INTEREST ON CONSTRUCTION COST

Assuming interest at 5% per annum. Assuming initial cost per mile of concrete at $40,000; macadam, $20,000; gravel, $15,000; earth, $3,000; sand, $0. Assuming annual maintenance per mile of concrete at $400; macadam, $300; gravel, $300; earth, $200; sand, $0. Bottom curve (A) represents costs per annum of mile of roadway, including maintenance and interest on investment.

should be served with a concrete paving not less than 16 ft. wide. For traffic amounting to as much as 2,000 vehicles per day, a concrete pavement 20 ft. wide should be used, and for traffic exceeding 1,500 vehicles per day a brick pavement is desirable. Traffic exceeding 2,000 vehicles per day should be served with a pavement not less than 20 ft. wide and constructed with concrete foundation not less than 5 ins. thick, with brick, wood block, rock asphalt, sheet asphalt, granite block, or some form of asphaltic concrete not less than 2 ins. thick, should be used. These conclusions are probably in keeping with economy when viewed only by the cost of building and maintaining the highway under the varying intensities of traffic for units formerly used. All of these types of construction are such as will enable traffic such as formerly was found on the highways to continue 365 days a year. Traffic amounting to less than 50 vehicles per day has been provided for by earth roads, occasionally graded and dragged. Traffic amounting to 1, 5 or 10 vehicles per day has been accustomed to getting along the best it could over the natural surface of the ground.

The approximate costs of transportation are as follows: Upon an unimproved road, 30 cts. per ton mile; on an improved earth or sand-clay road, 25 cts. per ton mile; on a hard gravel road, 20 cts. per ton mile; on a bituminous surfaced gravel road, 15 cts. per ton mile; on a concrete or brick road, 10 cts. per ton mile.

Fig. 3 is based on more conservative assumptions, as follows:—

Cost per ton mile on 9 ft. gravel road, 22 cts.
Cost per ton mile on 16 ft. gravel road, 21 cts.
Cost per ton mile on 16 ft. bituminous road, 20 cts.
Cost per ton mile on 16 ft. asphalt macadam road, 19 cts.
Cost per ton mile on 9 ft. concrete road, 18 cts.
Cost per ton mile on 16 ft. concrete road, 17 cts.
Cost per ton mile on 16 ft. brick road, 16 cts.

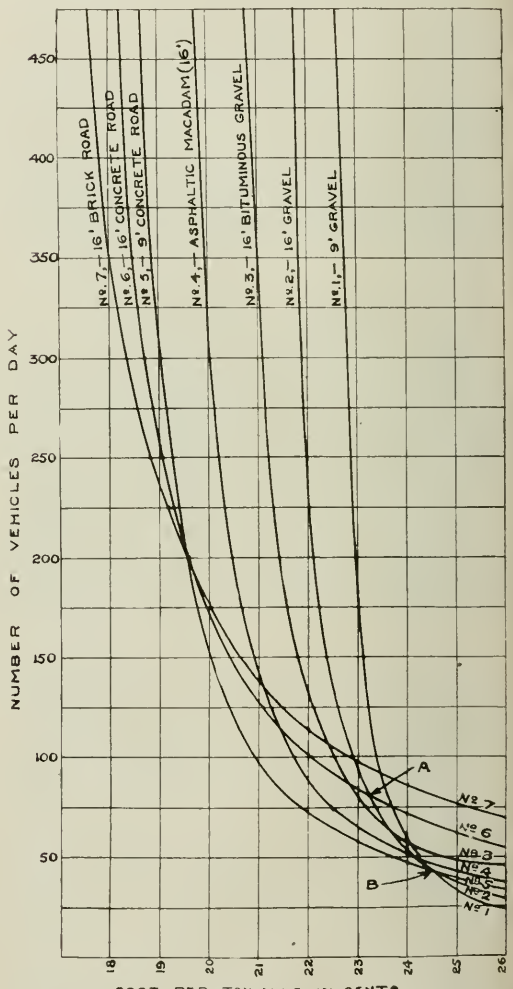

FIG. 3—TOTAL COST OF TRAFFIC PER TON MILE, INCLUDING TRANSPORTATION COSTS FOR VARIOUS TYPES OF SURFACES —SEE TABLE 1 FOR ASSUMPTIONS USED IN CALCULATING ABOVE CURVES

At point A. No. 2 equals No. 6, at 82¼ vehicles a day. At point B. No. 1 equals No. 5, at 43¼ vehicles a day.

The tonnage of traffic is assumed at one-half the number of vehicles, and the annual cost of the road assumed also is conservative and most favorable to the cheaper type of construction.

The cost of a road is essentially an annual cost. Man has not yet constructed any permanent structure and no highway has yet been constructed which, if it is used, does not require annual expenditure for maintenance. This rule applies to the Appian Way and every other road. We have not lost the art of road building, but we have lost the willingness to spend a sufficient amount of money on the road.

A permanent road is a road that is permanently maintained. The cost of a mile of road is the cost per mile of road per year. Too much attention is given to the original cost of construction and too little interest and attention is given to the cost of permanent service. A rational study of the cost of a mile of road must be arrived at by adding the interest on the original investment to the cost

TABLE 1—ASSUMPTIONS USED IN CALCULATING THE CURVES IN FIG. 3

Curve	Kind of Road	Cost of Surface only in Thousands of Dollars	Annual Maintenance*	Total Cost per Ton Mile (Dollars)
1....	9' Gravel	3	y	$(150+y)/182.5y+0.22$
2....	16' Gravel	5	$0.8y$	$(250+0.8y)/182.5y+0.21$
3....	16' Bit. Gravel	8	$0.6y$	$(400+0.6y)/182.5y+0.20$
4....	16' Asph. Mac.	9	$0.4y$	$(450+0.4y)/182.5y+0.19$
5....	9' Concrete	10	$0.2y$	$(500+0.2y)/182.5y+0.18$
6....	16' Concrete	18	$0.15y$	$(900+0.15y)/182.5y+0.17$
7....	16' Brick	25	$0.1y$	$(1,250+0.1y)/182.5y+0.16$

*y = number of vehicles a day (assumed to be ½ ton per vehicle).

of annual maintenance necessary to retain the original structure. This seems all that must be considered as a part of the cost of the road; however, the most important matter to be considered is the cost to the traffic using the highway as affected by the condition of the highway.

The use of the road occasions a cost to traffic amounting to a certain rate per ton mile. The improvement of the road is an economic waste unless a saving is effected by its expenditure as an investment in reducing the cost of the traffic using the road. The cost per mile of road per year should never exceed the reduction in the cost of transportation using said mile of road, made possible by the improvement.

E. H. Harriman is remembered as being a railway wizard as well as a financial genius. He took over unprofitable railways and bankrupt railways and spent millions of dollars on these losing ventures to improve the roadway, reducing the grades and laying heavier rail and building better track. He did not reduce the cost per mile per year of maintaining the track thereby, but he did reduce the cost per ton mile of all traffic using the road, thus transporting the tonnage at an enormous saving, which went into dividends. Yet he was able to accomplish only the small saving of approximately one-half of 1% per ton mile.

The seventeenth annual convention of the American Road Builders' Association will be held at Louisville, Ky., Feb. 9th to 13th, 1920. Both the sessions of the convention and the exhibition will be accommodated in the First Regiment Armory. About 53,000 sq. ft. of floor space will be available.

The United States Navy Department has just increased the pay of its technical employees. The force had been working for over seven months to obtain a greatly needed readjustment in compensation. Their case was handled through special wage boards at the navy yards and a department board.

Dr. C. J. Hastings, medical officer of health for the city of Toronto, favors the construction of another water works intake at that city, declaring that the supply should not be entirely dependent on one intake, as a serious situation might be created in case of certain accidents to the present system.

WATER WASTE CONTROL BY HOUSE INSPECTIONS WITH DISTRICT METERING*

By E. D. Case
Vice-President, The Pitometer Co., New York City

HOW to control waste of water in city distribution systems is a problem that is becoming of greater importance each year. The old idea that water should be as "free as air" is now obsolete. The increase in cost of extensions which are necessary if waste is not curtailed, due to high price of pipe, building material, labor, etc., has made it imperative that every water works manager who desires maximum efficiency in his plant, take steps not only to reduce waste to a minimum, but to make such a reduction permanent.

Water waste may be said to come under two general heads: (1)—Underground leakage; and (2)—House waste. While the first item exists to a greater or less extent in all water works systems, it is usually smaller by comparison to the second, especially in unmetered plants. The item of house waste may be further divided into three sub-heads:—(1)—Wilful waste; (2)—Leaking services; and (3)—Leaking fixtures.

Development of Deacon System

The most obvious and effective means of controlling waste of this kind is to place meters on all services. The owner will not run water for cooling purposes in summer, or allow his faucets to run continuously to prevent freezing in winter, if he knows that every cubic foot of water wasted will appear in dollars and cents on his next water bill. Furthermore, when paying for water on such a basis, he loses no time in repairing leaks in his fixtures or services as soon as they make themselves evident.

Unfortunately, however, local conditions make universal metering impossible in a great number of places. Either sentiment is against this method of selling water, or the first cost of installation is prohibitive and the manager must look about for some other method of controlling waste. Fortunately, there is one at hand which when properly applied will prove quite as effective as universal metering. This system may be described briefly as house-to-house inspections under the supervision of a district meter. It is by no means a new idea, as it is simply a development of the "Deacon Meter System," originated by George F. Deacon, engineer of the Liverpool (England) water works. The scheme in general at that time was as follows:—

New Portable Flow Meter

The distribution system was divided into districts by valve operation, and a meter especially designed for the purpose, called a "Deacon Meter," was placed in a vault on the main supplying each district with water. By cutting a block out of the district, or by shutting off the service, the amount of water used or wasted in this block, or through this service, was recorded by the meter. Inspectors were then sent into blocks where flows were abnormally high, and the cause of the high flow located and the leaks repaired.

This system was almost universally adopted throughout Great Britain, with the result that the per capita consumption in British cities at the present time is remarkably low. The accompanying table shows the per capita in some of the larger cities in Great Britain.

The "Deacon Meter System" was adopted by the city of Boston in 1881, with considerable success, but its use did not become very popular in the United States owing to the large cost involved in installing the district meters, also due to the fact that they deteriorated very rapidly and repairs and replacements were constantly needed, which made the cost of maintaining them very high. These drawbacks were overcome about 1900 by the development of a portable flow meter, called the "Pitometer," an application of the principle of the Pitot tube. Practically the same methods were used, but instead of permanently setting a

*From a paper read at a recent convention of the Southwestern Water Works Association.

large meter on the supply line to each district, all that was necessary with the portable instrument was to tap each supply line with a standard 1-in. corporation cock, and the flow meter was moved from one gauging point to another as the occasion demanded.

This system was first used in Terre Haute, Ind., in 1897, and later in Columbus, Ohio, in 1902. Since that time over 200 cities of the United States have adopted this method of controlling water waste, and from year to year the system has become more complete until at the present time its efficiency is unquestioned.

Probably the most successful results of recent years have been obtained in Trenton, N.J., and Buffalo, N.Y. In Trenton, the daily consumption had gradually increased from 9,000,000 gals. in 1902 to 21,000,000 gals. in 1913. This was partly due to increase in population and industrial use, but in most part was due to the fact that waste conditions were becoming greater as no steps were taken to curtail them. In 1914, when the population supplied was approximately 125,000, the "Pitometer system" of controlling water waste was installed, with the result that in a year's time the consumption had been reduced to 15,000,000 gals. a day. If nothing had been done to stop the waste, the consumption would have been about 27,000,000 gals. per day, based on the average rate of increase for the ten preceeding years. This means that by installing the system of waste control, a saving of $4.40 a day was made in coal alone. In addition, the need of a new reservoir and a new pump was put off indefinitely, together with the resulting necessity for larger mains. These extensions would have cost approximately $1,000,000. By repeating the district house-to-house inspections under the supervision of the "Pitometer," this reduction in waste has been made permanent up to the present time.

City.	Population.	Average per capita consumption, gallons daily.
Aberdeen	155,000	54.0

*Adjacent communities also supplied.

The results obtained by the city of Buffalo have been perhaps even more remarkable, inasmuch as it was necessary to carry on the work on a much larger scale than in Trenton. For a great many years Buffalo had the distinction of having the highest per capita consumption of any city in the United States. In 1917, just prior to the start of the water waste survey, about 180,000,000 gals. a day were being pumped into the mains, or a per capita of approximately 360 gals. In June, 1917, the "Pitometer system" of waste control was installed, and the daily consumption has now been reduced to about 120,000,000 gals. a day, or a per capita of 240 gals., although the first inspections have not been extended over the entire city. Of this amount, 100 gals. daily per capita are sold to the industrial consumers, leaving a domestic per capita of about 140 gals. This is still far in excess of the actual need of domestic consumers, but is being reduced day by day, and within the next year will undoubtedly reach a reasonable figure. What these results will mean to the city of Buffalo may be seen from the following facts:—

One Pumping Station Eliminated

The water is pumped from two pumping stations, each containing five 30,000,000-gal. pumps, with an approximate capacity of 150,000,000 gals. a day. The present daily pumpage is within the capacity of one station, and for the past six months only one pump has been in operation in the second station. When the margin of safety becomes a little greater, this station will be put into reserve and the entire load carried by one station. An enormous saving will result in operating costs.

For the purpose of the survey, the city was divided into ten sections and each section subdivided into a number of districts. The flow was then measured into each district by the "Pitometer," and further investigations made by subdividing each district at night, so that the rate of flow between each pair of valves was determined. Wherever this seemed excessively high, inspectors were sent into the blocks to locate and stop leaks. Each inspector was equipped with a blank form, which enables him to report the number, location and cause of all leaks discovered on the services or on the premises of consumers. Notices were left with the property owner, and a duplicate filed in the water works office, which required that the leaks be stopped within a designated number of days, with a penalty of shutting off the service in case repairs were not made. After re-inspections had been made to determine that all waste had been stopped, a remeasurement was made of the entire district and the results recorded. These results demonstrated the efficiency of this system.

Periodical Remeasurements

In order to discover the permanancy of the reduction in the various sections of the city, re-measurements were made of the flow in typical districts after periods of six, twelve and eighteen months had elapsed. In this way it was determined that in some sections of the city the waste had not returned in a sufficient amount to warrant reinspections until a period of eighteen months had elapsed. In other sections the investigations proved that in order to control waste, yearly inspections should be made; while in still other sections, notably those containing the poorer class of consumers, with exposed plumbing and anti-freezing toilets, inspections every six months, or even oftener, were necessary in order to control the waste.

In some cities it has been found practical to combine a system of selective metering with house-to-house inspections, which has been productive of even more satisfactory and permanent results. This system permits the metering of all wasteful commercial users of water, such as garages, livery stables, laundries, bakeries, saloons, etc., as well as metering the domestic consumer in cases where the officials are convinced, by repeated inspections, that this is the only way of compelling the owner to keep his plumbing in repair.

Probably a great many water works managers or superintendents will say that they have tried to reduce waste by house-to-house inspections, but that either no reduction in the daily consumption has resulted, or what reduction has occurred has not been sufficient to be of any practical value. This was the situation in nearly all of the unmetered cities where the "Pitometer system" has been introduced in the past twenty years. It is a matter of interest to note that inspections had been carried on for a number of years previous to the installation of this system in Buffalo, but in spite of that fact, the consumption was gradually increasing each year. The same force which had been employed in carrying on this work was used in making the systematic inspections under the supervision of the "Pitometer," and the increase in the efficiency of the inspections is well demonstrated by the results obtained. The reason is easily explained:—

Efficiency of Work Increased

When the inspections are made under the supervision of the "Pitometer," the inspector knows the amount of waste in each block before he starts his inspections. He also knows that there will be a remeasurement after repairs have been made, and if the flow has not been reduced to a satisfactory amount, further inspections will have to be made. This arouses his personal interest and enthusiasm, and the efficiency and thoroughness of his work increases correspondingly.

All Must Curtail Waste

Every city of Canada and the United States where the consumption figures show the existence of water waste, must some day take steps to curtail this waste. The leaks will not stop of themselves, and it is not only uneconomical and impractical to continue to install new pumps, build new reservoirs and lay new mains, but in many cases it is impossible on account of insufficient supply.

The fact that a city or town has an inexhaustible water supply, as is the case of those situated on lakes or rivers, is no reason for allowing waste to exist. No matter what the conditions are, it can only be brought to the consumer at considerable expense, and it is inexcusable to permit the waste of water on this account when such waste can be eliminated and controlled at a nominal expense.

Hopeless if Too Late

The fact cannot be emphasized too strongly that when the city is actually facing a water shortage, it is usually too late to save the situation by reducing the waste. It is then almost invariably necessary to install the new pump, to build the new reservoir or to lay the new main, thereby burdening the city with a much greater expenditure. The far-seeing water works manager or superintendent will never allow conditions in his plant to reach this point, when they may be avoided by comparatively small expense and effort on his part.

A very curious situation was brought to light some years ago in a large office building, where an apparently excessive consumption caused the water officials to attach a meter to the service pipe for the purpose of arriving at a suitable charge. It was hardly to be believed, but the registration by the meter showed that more water was being consumed at night, when the building was empty save for the janitor and family, than during the day, with all the suites occupied and water being freely used by all. A careful investigation was made, and it was found that all the toilets were fitted with a very poorly-constructed ball-cock fixture, which became disarranged every night by the increased pressure in the mains. This allowed a steady flow from the tanks, down the waste pipes, that lasted throughout the entire night all over the building until the day usage again reduced the pressure. Naturally, the owners of the building had a heavy water bill, but, needless to say, the wasteful fixtures were speedily replaced by others of a better kind and this ususual and costly source of waste was closed.

PROPORTIONING OF PIT-RUN GRAVEL FOR CONCRETE*

By Prof. R. W. Crum
Iowa State College, Ames, Iowa

THE factors upon which the strength of concrete must depend are (1) the density of the concrete, and (2) the extent to which the particles are cemented together. The latter factor depends upon the amount of cement in a given volume, and upon the total surface area of the particles.

Table I.—Ratio of Cement to Aggregate Constant

Per cent of "Sand" in Aggregate, by Weight.	Proportions (1:5).	Density.	Water, per cent of dry materials.	Compressive Strength, lb. per sq. in.
42	1:2:3	0 789	9 33	1600
55	1:2 3/4 : 2 1/4	0 770	10 65	1200
75	1:3 3/4 : 1 1/4	0 737	12 65	920
95	1:4 3/4 : 1/4	0 673	15 30	480

Inasmuch as numerous authorities are agreed that the density of the mixture is partly and the surface area wholly dependent upon the grading of the aggregate, and that the density also depends upon the consistency, or amount of water in the mixture, the writer has formulated for his own use the following rule for proportioning concrete mixtures:—

Use the best graded aggregate available, enough cement to make concrete of the class desired, and mix with the least amount of water which will yield a workable mixture for the conditions under which the concrete is to be placed.

Table II.—Physical Characteristics of Aggregates Used

The material to be considered in this paper is pit-run gravel, to be used without change as it comes from the pit. The problem is to establish some relation between grading and the amount of cement such that, for mixtures of the

*Paper read at the annual meeting of the American Society for Testing Materials, June 24th to 27th, 1919.

same plastic consistency, concretes of equivalent strength could be designed.

To establish such a workable relation, it is necessary to express the grading of the gravel by numerical functions. Other experimenters, notably Abrams and Edwards, have done so, and their work could be used as a basis for proportioning pit-run materials. However, both Abrams' "Fineness Modulus" and Edwards' "Surface Area" method require the making of a complete sieve analysis of the material. The method herein described requires the separation of a sample into only two sizes and a simple determination of the weight per cubic foot of the loose gravel.

The principal conclusion resulting from the investigation carried out is that the grading of pit-run gravel may be measured by the ratio of fine aggregate to total aggregate (that is, percentage of fine aggregate in total) and by the weight per cubic foot of the material, measured loose. For purposes of commercial convenience the dividing line between fine and coarse aggregate is taken on the common No. 4 sieve. In the following discussion, fine aggregate as defined above will be called "sand," and coarse aggregate "pebbles."

Two assumptions have often been made by users in proportioning the cement to pit-run gravels:—

1. That the ratio of cement to total aggregate should be a constant.

2. That the ratio of cement to the sand portion of the aggregate should be a constant.

The former is wrong and on the unsafe side. The latter is also wrong but is on the side of safety.

Cement to Aggregate Constant

Table I. is typical of the strength of concretes made under the assumption that the ratio of cement to total aggregate should be kept constant. Further demonstration of the fallacy of this assumption is not necessary.

Cement to Sand Constant

The assumption that the ratio of cement to percentage of sand in the gravel should be a constant was investigated in twenty-four series of tests. Materials from several localities and two classes of concrete were used. Table II. gives physical characteristics of the aggregates used in the investigations described herein.

Each series comprised tests of gravels containing respectively 42, 55, 75 and 95 per cent. by weight, of sand. The mixtures were made arbitrarily by combining sand and pebbles in the right amounts. The same sand and pebbles were used in each mixture in a series. Each series included tests of forty specimens. Five specimens were broken for each test of a mixture. Specimens from all series were tested at 28 days old; specimens from some series were tested at 7 days and from others at 6 months. Specimens were 8 by 16-in. or 6 by 12-in. cylinders stored in water.

In some of the series the No. 8 sieve was taken as the dividing line between sand and pebbles. The general result was very similar to that obtained with the No. 4 sieve.

In Table III. are given typical results of these tests for three series, showing the variation in strength of concrete with the percentage of sand in the gravel, when the ratio of cement to sand is kept constant. The strength increases with the percentage of sand in every mixture in the table, save one, and the results are typical of all series.

Obviously, neither the ratio of cement to total aggregate, nor the ratio of cement to the sand portion, should be a constant, but for equivalent mixtures the ratio of cement to total aggregate should increase in some relation to the percentage of sand in the gravel. That this is a straight line relation is demonstrated as follows:—

TABLE III.—VARIATION IN COMPRESSIVE STRENGTH OF CONCRETE WITH THE PERCENTAGE OF SAND IN THE GRAVEL, WHEN THE RATIO OF CEMENT TO THE SAND PORTION OF THE GRAVEL IS KEPT CONSTANT

CEMENT TO SAND = 1:2 BY WEIGHT.

The "Sand" Method

The "sand" method of making concretes of equivalent strength, using gravels of varying sand content, depends upon the assumption that there is a direct relation between the strength of concrete and the ratio

$$c/[1-(c+s+p)] = c/(1-d),$$

in which c = absolute volume of cement, s = absolute volume of sand particles, and p = absolute volume of pebbles in a unit volume of freshly made concrete; d = coefficient of density = absolute volume of solid material in a unit volume of freshly made concrete = $c+s+p$; and $1-d$ = volume of air and water voids.

DATA CONCERNING PROPORTIONS FROM TYPICAL SERIES

75	0 132	0 456	0.145	0.733	. .
95	0 167	0 525	0.026	0 718	. . .

By absolute volume of a granular material is meant the actual sum of the volumes of all the particles; it is expressed as the fractional part of the total space occupied by the material.

The quantities are computed as shown in Taylor and Thompson's "Treatise on Concrete."

Fig. 1 demonstrates the truth of the assumption that, other things being equal, the strength varies with $c/(1-d)$.

The tests grouped on this diagram are comparable by reason of being made from the same cement, similar materials, and subjected to the same conditions as to making, molding and curing. Each point is derived from the average tests of five specimens. Diagrams of other groups of tests comparable among themselves give similar results. A similar diagram published in the last (1918) edition of Johnson's "Materials of Construction," computed from data published in U.S. Bureau of Standards Technologic Paper No. 58, corroborates this assumption.

In order to compute proportions for equivalent strength, it is necessary to assume for each class of concrete that some mixture is satisfactory. For the three classes of concrete considered in this paper, the following mixtures were taken as the basis:—

Class I.—Proportion 1: 4½, gravel containing 42 per cent. sand.

Class II.—Proportion 1: 5½, gravel containing 42 per cent. sand.

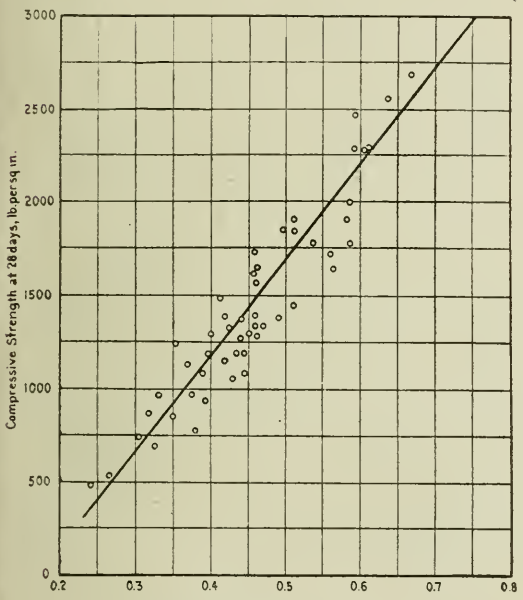

FIG. 1.—RELATION BETWEEN COMPRESSIVE STRENGTH OF CONCRETE AND THE RATIO $c/(1-d)$

c = Absolute Volume of Cement and (1—d) = Volume of Air and Water Voids in a Unit Volume.

Class III.—Proportion 1: 7, gravel containing 42 per cent. sand.

Taking each series of tests by itself, the probable proportions to use with the different percentages of sand in the aggregate, to yield concrete equivalent to the one having 42 per cent. of sand in the aggregate were derived as follows:—

To arrange the proportions for equivalent strength it is necessary to so change the relation between the absolute volumes of cement and aggregate that the ratio $c/(1-d)$ will, in each case, become equal to 0.455. The adjustment can be made by increasing or decreasing c and decreasing or increasing $s+p$, so that d will be unchanged, thus:—

Let c', s' and p' be the new values required for c, s and p, respectively. As explained above, these values are the percentages of absolute volumes of the materials in a unit volume of freshly made concrete.

$$c'/(1-d) = c'/[1-(c'+s'+p')] = 0.455$$

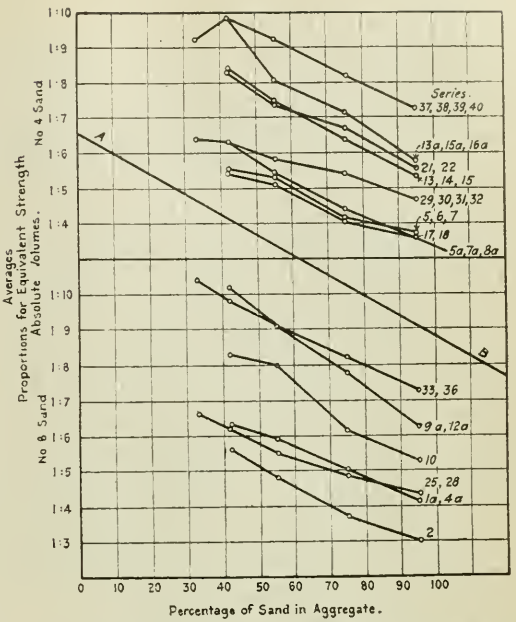

FIG. 2.—RELATION BETWEEN PERCENTAGE OF SAND IN GRAVEL, AND THEORETICAL PROPORTIONS BY ABSOLUTE VOLUME, NECESSARY TO YIELD CONCRETE EQUIVALENT TO A GIVEN BASE MIXTURE

Therefore, to convert the mixture containing 33 per cent. of sand:—

$$\begin{aligned} c'/(1-0.763) &= 0.455 \\ c' &= 0.108 \\ d &= c'+s'+p' \\ 0.763 &= 0.108+(s'+p') \\ (s'+p') &= 0.655 \end{aligned}$$

Accordingly the ratio of absolute volume of cement to absolute volume of total aggregate, required to make a proportion using the 33-per-cent. sand mixture equivalent to the 42-per-cent. sand mixture is 108: 655, or 1: 67.

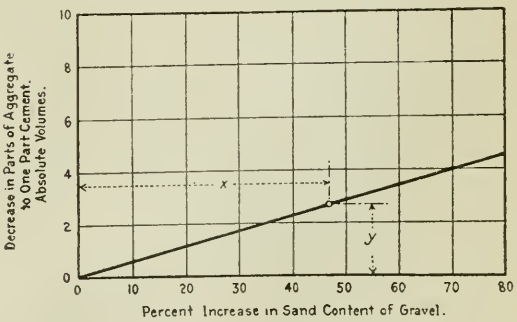

FIG. 3

To determine the amount of cement to use with a given pit-run gravel to yield a concrete equivalent to a given mixture of sand and gravel:

1. Reduce the proportion of the standard mix to the basis of absolute volume.
2. Determine from curve decrease in parts of aggregate corresponding to increase in percentage of sand in aggregate.
3. Change the absolute volume proportions thus found to the loose volume basis.

Formula for computing Item 2.

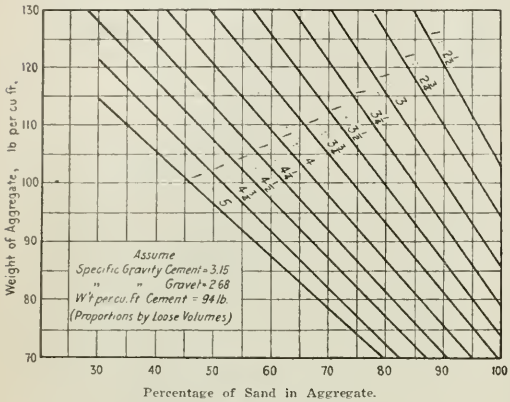
$\tan \alpha = 3.6/62 = 0.058$ (See A B, Fig. 2)

$y = x \tan \alpha = 0.058\ x$

New proportions for the 55, 75 and 95-per-cent. mixtures were computed in the same way.

This theory is approximate, not rigorous, for when the concrete is actually made, the density d will be affected a small amount. The result obtained, however, is within the probable range of accuracy in making the concrete.

The proportions thus derived are by absolute volumes. To make these proportions usable it is necessary to convert them to a loose volume basis, which requires the weight per



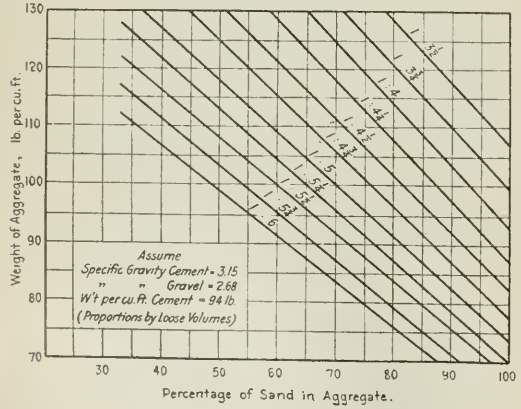
Weight of Aggregate, lb per cu ft.
Percentage of Sand in Aggregate.
Assume
Specific Gravity Cement = 3.15
" " Gravel = 2.68
Wt per cu. Ft Cement = 94 lb.
(Proportions by Loose Volumes)

Fig. 4—Diagram for Use in Proportioning Pit-Run Gravel for Class I. Concrete

cubic foot of cement and loose aggregate. Assuming cement to weigh 94 lbs. per cu. ft., its specific gravity = 3.14, and that of the aggregate = 2.68, absolute volume proportion of aggregate (cement = 1) may be changed to loose volume proportion by the following equation: Aggregate (loose) equals aggregate (absolute) multiplied by 80 and divided by the weight per cu. ft. of aggregate (loose).

In this way the absolute proportions and loose volume proportions of materials to yield concrete equivalent in strength to the one in each series whose aggregate contained 42 per cent. of sand, was determined for aggregates containing 33, 55, 75 and 95 per cent. of sand.

In Fig. 2 the relation between the proportions for equivalent strength by absolute volume and percentage of



Weight of Aggregate, lb. per cu. ft.

Fig. 5—Diagram for Use in Proportioning Pit-Run Gravel for Class II. Concrete

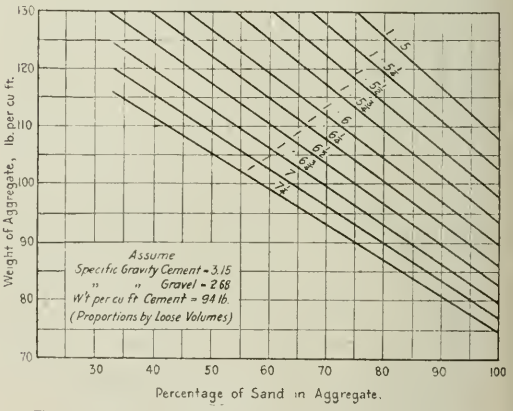
sand in aggregate is shown for all of the specimens tested. Each line is the average of results from 3 or 4 different sands, and, therefore, represents the conclusion drawn from 3 or 4 series of tests. Each point is the average of from 75 to 100 individual specimens.

The conclusion drawn from a study of this diagram is this: The relation between proportions by absolute volumes to give equivalent strength, and sand content of the aggregate, varies uniformly and at approximately the same rate for all degrees of quality of concrete. The line AB in the diagram is established to indicate this rate of variation as an average.

To make use of this diagram to determine the proportions to use with a given material having a certain sand content, it is necessary first to assume an aggregate and proportion known to be satisfactory. Locate the point representing this known condition and draw a line through it parallel to AB. Then pick from this line of proportions the proportion corresponding to the given aggregate.

To make a single line diagram of general application, the line AB (Fig. 2) is plotted on Fig. 3, using for ordinates the decrease in parts of aggregate, and for abscissas the increase in percentage of sand in the aggregate. This diagram can be used for determining proportions in a case when the proper data are at hand, or for writing a table of proportions for equivalent mixtures of cement and pit-run gravels in general. Such a table could not be exact for all materials, but it would give a very reasonable set of proportions to use with Iowa gravels.

Example: Assume that an aggregate containing 42 per cent. of sand, and weighing 112 lbs. per cu. ft., makes a satisfactory concrete in the proportion 1:4½ loose volume.



Weight of Aggregate, lb. per cu ft.
Percentage of Sand in Aggregate.
Assume
Specific Gravity Cement = 3.15
" " Gravel = 2.68
Wt per cu ft Cement = 94 lb.
(Proportions by Loose Volumes)

Fig. 6—Diagram for Use in Proportioning Pit-Run Gravel for Class III. Concrete

What proportion should be used with a similar gravel containing 75 per cent. of sand and weighing 107.1 lb. per cu. ft?

Change the proportion 1:4½ to a proportion by absolute volume, thus:—

$4.5 \times 112/80 = 6.3$. Proportion (absolute) = 1: 6.3.

The increase in percentage of sand is 33. From Fig. 3 the corresponding decrease in parts of aggregate is 1.9. 6.3—1.9 = 4.4. Therefore, the proportion for the aggregate containing 75 per cent. sand should be 1: 4.4, absolute volumes, or 1: 3.3 loose volumes.

Fig. 3 is perfectly general and can be used for designing mixtures equivalent to any assumed base.

The diagrams in Figs 4, 5 and 6 have been arranged for convenience in proportioning pit-run gravels for three classes of concrete:—

Class I., suitable for reinforced concrete in general, water-tight concrete, and base course of concrete pavement. It should range in strength from 2,400 to 3,000 lbs. per sq. in.

Class II., suitable for first-class foundations, gravity section piers and abutments for bridges, and base course of non-reinforced floors and walks. It should range in strength from 1,800 to 2,400 lbs. per sq. in.

Class III., suitable for large foundations and heavy mass work in general. It should range in strength from 1,200 to 1,800 lbs. per sq. in.

Verification

Table IV. shows the resulting strengths of laboratory specimens made in accordance with the foregoing principles. It is believed that these results verify the reasonableness of the method of proportioining pit-run gravels described. Series Nos. 48, 49 and 50 were made about one year after Series Nos. 46 and 47 from different materials, and by a different operator. The consistency was approximately the same in both groups.

Fig. 7, compiled from the averages of numerous tests of various materials and classes of concrete, illustrates in

general the decrease in strength when the ratio of cement to total aggregate is made a constant, the increase in strength when the ratio of cement to sand portion of aggregate is constant, and the equivalent strength when the mixtures are proportioned according to the foregoing method.

The writer expects further to verify the method by making and testing field samples from a large number of jobs on which such material is used.

Application

The mere fact that pit-run gravel is ordinarily not a well-graded material, is not an insuperable obstacle to its use. All that is required is its use with the right amounts of cement and water. The principal difficulty is the fact that the product of a pit is often extremely variable as regards grading. Nevertheless, large amounts of this material are being used, and since in many cases great economy results from its use, it would seem that engineers should be prepared to lay down rules for the proper handling of this material.

This investigation was undertaken by the Engineering Experiment Station of the Iowa State College, at the request of the Iowa State Highway Commission, and their

present specifications for the use of pit-run gravel are based upon this work.

An important advantage of the method of proportioning described in this paper is the simplicity of the field tests required. The percentage of fine aggregate (or sand) in the

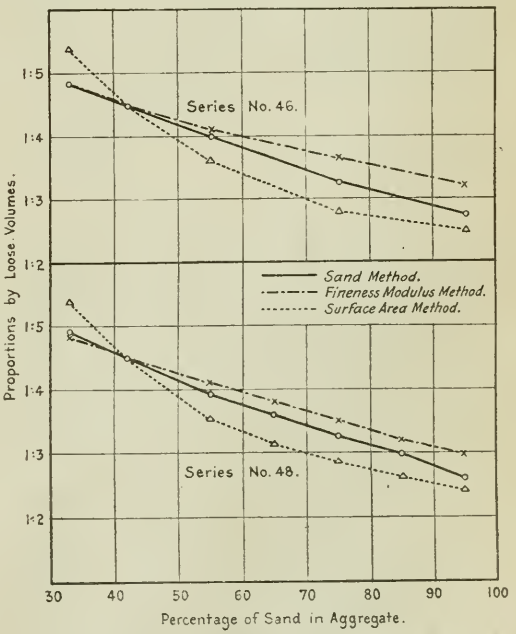

FIG. 8—RELATION BETWEEN THREE METHODS FOR DERIVING PROPORTIONS TO YIELD CONCRETE OF EQUIVALENT STRENGTH, "FINENESS MODULUS," "SURFACE AREA," AND THE "SAND" METHODS

gravel, and the weight per cubic foot, can easily be determined with simple apparatus.

In practical use, frequent analysis must be made and the proportions changed as often as is necessary to agree with the variations in the material.

Comparison With Other Methods

Fig. 8 shows a comparison between three methods of proportioning pit-run gravels to produce concrete of equivalent strength, the "Sand" method, as described in this paper, the "Fineness Modulus" method of Abrams, and the "Surface Area" method of Edwards. The proportions necessary to use with gravels containing various percentages of sand, to make concrete equivalent in strength to that of a 1: 4½ mixture in which the gravel contained 42 per cent. of sand, were computed by each method. The materials, and approximately the mixtures, are those shown in Table IV.

The proportions shown on this diagram are the theoretical mixtures as computed. In the greatest number of instances in which this material is used, it will not be practicable to state the proportions any closer than the nearest half or quarter part of aggregate. When the proportions in the diagram are changed so that the parts of aggregate to one part of cement conform to the nearest quarter part, it will be found that there is very little difference between the "Sand" and "Fineness Modulus" methods. The "Surface Area" method appears to call for somewhat richer mixtures.

LETTER TO THE EDITOR—CORRECTION

Sir,—We are very pleased with the notice given our penetration dial in your issue of July 10th, but wish to call your attention to an error in connection therewith. While it is true that the idea of advocating concordant action in specifying the penetration of asphalt for the various types of pavement made with that material, where traffic conditions and climate are the same, was indicated by the paper I prepared for the last convention of the A.S.M.I. at Buffalo, in October, 1918, nevertheless the idea of the dial belongs to our chief chemist, Leroy M. Law. Accordingly, I feel that you should not credit me with a creation which is the result of the skill and ingenuity of another.

J. R. DRANEY,
General Sales Manager,
U. S. Asphalt Refining Co.

New York City, July 14th, 1919.

JAPANESE WATER POWER SURVEY

THE value of water power as an indispensable adjunct to industrial development is being universally recognized. Japan has lately set aside a sum equivalent to over $400,000 for the investigation of sites for hydro-electric power plants and for the collection of reliable data for use in connection with future hydro-electric undertakings in that country. The programme of work includes the selection of 635 power sites; the only sites to be surveyed at present are those where more than 1,000 h.p. can be obtained by economical exploitation. There is also provision for the establishment of numerous stream-gauging stations and of new meteorological observatories. This work is to be completed by the end of next September.

Canada is justly proud of her water power resources, both latent and developed, and, in this connection, it is of interest to note the progress made in Japan. Hydro-electric plants in that country already utilize more than 1,000,000 h.p., and a further 2,000,000 h.p. is under lease for development. Construction work for about one-half of the latter quantity is now being proceeded with, and it is estimated that some 5,000,000 h.p. is capable of development on commercial lines. In Canada, the total hydro-electric power developed is over 1,800,000 h.p.—By L. G. Denis, writing in "Conservation," an official journal published by the Commission of Conservation, Ottawa.

TNT AS A BLASTING EXPLOSIVE

By Charles E. Munroe and Spencer P. Howell
Bureau of Mines, Washington, D.C.

TRINITROTOLUENE is an explosive which is obtained by acting upon toluene with nitric acid in the presence of sulphuric acid. Toluene is a liquid substance which is produced from soft coal in the process of making coke, coal gas and coal tar, and it is recovered for use from both the gas and the tar. It is also made in other ways. The name TNT is an abbreviation of trinitrotoluene, which is the name given by chemists to the explosive in order to state its composition while designating it, and to thus distinguish it from many other nitrotoluenes known to them.

History

TNT has been known to chemists since 1863, and it was adopted as a military service explosive by 1902, but it did not become widely known until the Great War, when it came to be extensively used as bursting charges for high explosive shells, depth bombs, mines, torpedoes and other devices, and in demolitions where very violent detonation effects were sought to be produced with the largest measure of safety from these effects to the users. It was also used in admixture with other substances to produce other military explosives, such as amatol and sodatol.

Safety

Because of the devastating effects produced by the explosion of these devices charged with TNT, and because of the many most disastrous accidents which have occurred during the manufacture and transportation of large quantities of TNT under the hurried conditions necessitated by war conditions, many have been led to conclude that TNT is an especially dangerous explosive, but it really possesses characteristics which render it less dangerous than many explosives generally used in our industries. Thus it has been found more difficult to explode it with certainty than nitroglycerine, dynamite or gun cotton. In fact it was considered so safe that in 1910 the British government, on advice of its explosives experts, issued an order-in-council exempting it from being deemed an explosive, and subject therefore to the explosives regulations, during manufacture and storage unconditionally, and when conveyed and imported, provided it was perfectly packed. But this order has since been rescinded, and it may be proper to say in this connection that all substances possessing explosive properties should be treated with special care and surrounded by safeguards.

Industrial Use

With the cessation of hostilities this continent found itself with very large supplies of TNT on hand. So large, indeed, that it was deemed unwise to keep all of it in storage awaiting future military use, and it was proposed to devote many million pounds of it to industrial use. Now, although nitrotoluenes in admixture with other substances have been used as industrial explosives to a certain extent for more than a decade, TNT, as such, for several reasons, and especially because when its special value as a military explosive was recognized stocks of it were accumulated for war purposes, has not been used in industrial blasting except tentatively. It is not surprising, therefore, that objections should have been made to its suggested use as an industrial blasting agent, and doubts expressed as to its operativeness. It is the purpose of this paper to show how TNT may be safely and efficiently used in industrial blasting operations by those skilled in blasting and to correct many erroneous or misleading statements which have been circulated as to the properties of TNT by giving the results of careful experiments and observations, many of which have recently been made at the United States Bureau of Mines Experiment Station.

General Characteristics

When chemically pure TNT is a pale yellow, crystalline substance which acquires a deep yellow to brown color on exposure to light. It melts at about 80.5°C. (177.9°F.), and

when in the molten state it is cast into shells or run into cold water where it is granulated, by chilling, in the form of pebbles or pellets. TNT may, therefore, appear in granulated crystalline form, in pebbled or pelleted form, or in blocks or other cast forms. As offered by the Department of the Interior for use in blasting it is in the granulated crystalline form. Naturally, as produced on a large scale, TNT is not chemically pure, though the admixed substances are principally other nitrotoluenes which do not materially affect the explosive quality of the product though they do change its appearance and other physical characteristics. Thus the War Department secured and has alloted to the Department of the Interior for industrial use three grades of TNT as follows: Grade 1 having a setting point (S.P.) of 80°C. (176°F.); Grade 2, (S.P.) 79.5°C. (175.1°F.); and Grade 3, (S.P.) 76°C. (168.8°F.), the setting point of the molten TNT being employed by the Ordnance Corps, U.S.A., as the criterion of purity, because it is more readily observed with accuracy than the melting point of the solid. This Grade 1 appears as a dry granular crystalline powder, having a slight yellow color, and so fine that it will pass through a 30-mesh sieve. Because of its dryness it readily gives off dust; Grade 2 is a granular crystalline powder resembling light brown sugar, with a reddish tinge in color, and so fine that it will pass through a 12-mesh sieve. It is less dry and, therefore, less free-running and dusty than No. 1, and Grade 3 as a dry crystalline granular powder having a pale sulphur-yellow color, and so fine that it will pass through a 12-mesh sieve. It is not dusty, has the consistency of brown sugar, looks as if it were slightly moist, or greasy, and shows a tendency to cake, and is less free-running than No. 2.

Solubility and Hygroscopicity

TNT is almost insoluble in water. According to Marshall, water at 15°C. (59°F.) dissolves 0.021 per cent. of it, and at 100°C. (212°F.) 0.164 per cent. That is, 100,000 parts of water at 15°C. dissolve 21 parts of TNT, and at 100°C., 164 parts. The solubility of the different grades mentioned above is of the same order as this. In fact, the lower grades, and especially Grade 3, have a greasy feel and appearance and are, to a degree, water repellant. The proved solubility of TNT shows that it cannot be deliquescent ,or more than slightly, if at all, hygroscopic. Investigation at the Bureau of Mines Experiment Station has shown that it absorbs moisture when exposed to the atmosphere to about the same extent as powdered glass. This is for all practical purposes an entirely negligible quantity.

Packages

Military TNT, as offered for use in industrial operations, is packed in the granular crystalline form, in boxes made of white pine, ⅝-inches thick. The boxes are lock-cornered construction, and lined with paraffined paper. Most of the boxes of TNT received at the Explosive Experiment Station of the bureau were 22⅜ by 15¼ by 13 inches outside dimensions, and occupy a volume of 4,436 cubic inches (2.57 cubic feet). The boxes contained 100 pounds of TNT, and their gross weight averaged 113 pounds. It is possible that the boxes supplied by other manufacturers differ in dimensions and weight from these. The tops and bottoms are fastened on with nails. In opening the boxes, if force is necessary, the covers should be pryed off with wooden wedges. Grades 2 and 3 tend to cake during storage, and the lumps must be broken up to render the explosive "free running," so that it may be made into cartridges or loaded directly into bore holes. They may be so broken by pressing them with a wooden paddle or striking them light blows with a wooden mallet on a wooden surface.

Poisoning

TNT has a faint smell and a bitter taste. It produces brown stains on the skin which are difficult of removal. It is toxic and may produce poisoning by being inhaled as dust, or taken into the mouth, or by absorption through the skin but, unlike nitroglycerine, which produces severe headaches if but even a minute quantity touches the skin, rather long contact with TNT is required before its toxic effects become of moment. Nevertheless, those engaged in handling it, crushing the lumps and loading it into cartridges should avoid getting it into the nose and mouth, and clean their hands thoroughly before eating.

Detonation

TNT is more difficult to detonate with certainty than nitro-glycerine, dynamite, or the explosives ordinarily used in engineering operations, in mining and in quarrying. TNT charges require a No. 8 detonator (blasting cap) or electric detonator, while dynamite and the other high explosives ordinarily used in industrial operations require but a No. 6 detonator. Objection has been raised to the use of TNT on the ground of the increased cost consequent on the use of this stronger detonator. From inspection of current price lists it appears that No. 8 detonators cost nine-tenths of a cent more apiece than No. 6 detonators, and that No. 8 electric detonators cost 1.7 cents more apiece than No. 6 electric detonators.

Sensitiveness

As shown by tests with the pendulum friction device, all the three grades of TNT are less sensitive to friction than 40% straight dynamite, gelatin dynamite or picric acid, and as shown by tests with the large impact machine, all are sensitive to percussion than 40% straight dynamite, amonia dynamite and nitrostarch powders. It may be set on fire, when it will burn, but this burning may change to a detonation. Hence TNT must be protected from fire and causes of fire, such as sparks, flame, heated bodies, friction, percussion and the like, as all explosives should be at all times.

Gaseous Products of Detonation

In tests made at the Pittsburg Experiment Station by detonating TNT, Grade 1, and collecting the gases, it was found that 454 grams (one pound) of the explosive gave 506.5 liters of gases having the following compositions:—

Table I.—Gases from Detonation of Grade 1, TNT.

	Per cent. by volume.	Volume in liters.
Carbon dioxide	4.9	24.8
Oxygen	2.5	12.7
Carbon monoxide	46.6	236.0
Hydrogen	24.6	124.6
Methane	2.6	13.2
Nitrogen	18.8	95.2
	100.0	506.5

from which it appears that there was produced 46.6%, or 236 liters of a poisonous gas (CO), and 73.8%, or 373.8 liters of combustible gases (CO, H and CH_4). The tests of other grades of TNT gave similar, though not identical results, but all indicate it to be unsafe to use TNT in close places, such as underground workings and particularly coal mines. These results emphasize the importance of remaining away from the face of the blast after the explosion, until assured that the gases produced have been blown or have diffused away from the interstices of the debris. The safe waiting time will, of course, vary with the quantity of explosive fired, the location, such as a pocket, or valley, or plain, and the atmospheric conditions, particularly that of the force and direction of the wind. These precautions are such as should be taken with all explosives.

Relative Efficiency

In determining the relative efficiencies of explosives in use, the Bureau of Mines has long employed the "unit deflective charge," and the "rate of detonation" as criteria. The unit deflective charge is ascertained by exploding a known weight of the explosive in the ballistic pendulum and this term "unit deflective charge" is defined as "that weight of an explosive which will swing the ballistic pendulum the same distance as one-half pound of 40% straight nitro-

glycerin dynamite." It appears that the less the unit deflective charge, the greater the propulsive capacity of the explosive; hence, this is considered a measure of the ability of an explosive to dislodge and bring down material in which it is exploded.

Unit Deflective Charge

The unit deflective charge, in grams, of 40% dynamite and of Grades 1, 2 and 3 of TNT, with their corresponding percentage figures, using 40% dynamite as the basis of 100%, are given in the following tabulation:—

TABLE II.—UNIT DEFLECTIVE CHARGE OF FOUR EXPLOSIVES

	Dynamite	TNT		
Explosive.	40%.	1.	2.	3.
Unit deflective charge (grams) ..	227	201	199	209
Unit deflective charge (%)	100	113	114	109

From the above, it will be seen that each and every grade of TNT is stronger when so measured than 40% straight nitro-glycerin dynamite.

Rate of Detonation

The method of determining the rate of detonation is to charge the explosive in a file 1¼ inches in diameter and 42 inches long at normal density (that is, no unusual effort is made to get the explosive to a high density), and to fire the charge with a No. 8 electric detonator.

The "rate of detonation" is considered a measure of the ability of an explosive to disrupt and shatter material in which it is exploded.

The results of such tests are given in the following tabulation:—

TABLE III.—RATE OF DETONATION OF FOUR EXPLOSIVES

	Dynamite	TNT		
Explosive.	40%.	1.	2.	3.
Apparent specific gravity	1.24	0.91	0.88	0.86
Rate of detonation (meters per sec.)	4,772	4,747	4,852	4,482
Rate of detonation (%) .	100	99	102	94

Packing in Cartridges

It should be carefully noted that the comparisons made in the unit deflective charge table are by weight and in the rate of detonation table by volume. When either of the three grades of TNT are packed in cartridge cases, or in bore holes under ordinary tamping pressures, the apparent specific gravity of the charges vary from 0.81 to 0.95, while when 40% straight dynamite is so packed, the apparent specific gravity of its charges are from 1.15 to 1.34. It is evident, therefore, that for equal weights the TNT cartridges will be more bulky than the dynamite cartridges. As a consequence of this, larger bore holes must be used for TNT charges than for dynamite charges of equal weight. This presents an advantage for the dynamite over the TNT, but on the other hand, it has been observed that as the apparent specific gravity of the TNT approaches the lower limit given above, its resistance to wetting, when the cartridges are immersed in water, increases. Hence, it is recommended that except in assuredly dry holes, or in big blasts, where full boxes of the explosive may be fired in chambers, the TNT be packed for use in cartridges and that, as the No. 3 grade is the most water resistant of them all, it be packed at a low pressure and reserved for use in the especially wet work. To particularly distinguish the cartridges of grade 3, the wrappers may be of a specially chosen color or, better yet, they may be packed in paraffin coated wrappers and after the charge has been packed in these wrappers and the ends folded in, the ends should be redipped in the molten paraffin to completely seal them. For emergency use, newspaper may be employed for wrappers, being made up into cylinders of the desired dimensions by rolling about a pick handle or other convenient tool, but where considerable quantities are to be packed, it will be better to make a regular job of the operation, and to pack the explosive in the standard manilla wrappers, made by means of a cartridge machine.

It is only in large scale operations of crushing and repacking TNT into cartridges that there is much likelihood of any one becoming poisoned, for, as a rule, it requires continued contact with it through some period of time to produce this result. In handling TNT the following rules should be observed:—

Precautions in Packing

1. Only persons in good health should be employed.

2. Special clothing should be provided to be used only during working hours. Gauntleted gloves may be worn, but this is not necessary.

3. The hands and face should be washed before meals and before leaving the factory.

4. Care should be taken that none of the TNT comes in contact with the mucous membrane, such as that of the mouth, nose, eyes, etc. Workers should, therefore, be cautioned against touching these parts with their hands, or taking a chew of tobacco.

Cases of TNT poisoning which have occurred in considerable numbers in the factories operated under war conditions, appear to have resulted from neglecting to observe all the foregoing rules.

This poisoning is usually first evidenced by the appearance of a rash on the hands, neck or face. When this occurs, the case should receive prompt medical attention, and it would be desirable to transfer the person to other work. In this way, a worker who is easily susceptible to TNT poisoning will not be exposed to further danger. In factories where the opportunities for TNT poisoning are great, the effects are not usually evidenced until after five weeks of work.

Charging Bore Holes

TNT should be charged into bore holes, primed, tamped and stemmed in the manner customarily followed in the use of high explosives in blasting, special care being taken in charging wet holes not to tear or break the cartridge case or wrapper while loading it into the hole and tamping it. It may be used in chambering holes for subsequent charging with black blasting powder, just as dynamite is used. When TNT shots are fired, if the detonation is complete, there will be produced large volumes of dense, black smoke.

Practical Field Demonstrations

The practical value of TNT, grade 3, for general blasting purposes has been demonstrated by a number of field tests, such as adobe shots on boulders and concrete piers, blasting out oak stumps, splitting oak logs and shooting under water. In all the tests described herein the TNT was loaded in extemporized wrappers, made from newspapers, and detonated by a No. 8 electric detonator. A brief description of these tests, made at the Explosives Experiment Station by A. B. Coates, J. E. Tiffany and W. J. Montgomery, are as follows:—

Test No. 1—Adobe.—A 1½-pound charge of Grade 3 TNT was mudcapped with wet clay and fired on a sandstone boulder, 6 ft. long, 3 ft. wide and 1½ ft. thick. The largest piece obtained was 2 ft. by 2 ft. by 1 ft. Forty per cent. of the boulder was broken into fragments 2 ins. or less.

Test No. 2—Adobe.—In removing two concrete piers, 10 ft. long, 7 ft. high, 1½ ft. thick at top and 3½ ft. thick at bottom, an opportunity was given to compare TNT directly with 40% straight nitro-glycerin dynamite. All shots fired were adobe shots mudcapped with moistened clay. In six blasts, using a total weight of 10.7 pounds of TNT, 159.5 cubic feet of concrete were removed, or 14.9 cubic feet per pound of TNT, while in five blasts, using a total weight of 9.6 pounds of 40% straight nitro-glycerin dynamite, 135 cubic feet were removed, or 14.1 cubic feet per pound of 40% dynamite.

Test No. 3—Stump Blasting.—A solid oak stump 3 ft. in diameter, rooted in clay, was removed by the use of six 1½-pound charges of TNT, one charge being inserted under

ROAD TAX ON GASOLINE

RAISING money for roads has always been the hardest part of their construction. Various means have been suggested from time to time for financing roads more readily than by the present methods of taxation. Several months ago, C. A. Mullen, director of the paving department of the Milton Hersey Co., Ltd., Montreal, contributed an article to *The Canadian Engineer*, suggesting a wheel tax. Mr. Mullen now writes that his attention has been drawn to the possibility of raising funds by taxing the gasoline used by motor vehicles.

While this is not a new suggestion, having been discussed many years ago by Clifford Richardson, of the Barber Asphalt Paving Co., it is one which has not yet received the thorough consideration and discussion which it very evidently merits.

A tax on gasoline would in many ways be a very equitable method of raising funds for road construction. There is an analogy between the wheel tax and the gasoline tax, as both try to secure money from the actual users of the road in proportion to the service they receive. But the wheel tax does not take into consideration the extent to which the vehicle is used, while a tax on the gasoline is in direct relationship to the actual use. The more a vehicle is operated, naturally the more gasoline it requires; also, the heavier the vehicle, the greater the amount of gasoline it consumes per mile. Therefore a tax on gasoline would approximately be a tax per ton-mile.

As Mr. Mullen points out, there would be certain difficulties to be solved, such as finding a means for taxing vehicles not using gasoline, and devising simple ways of rebating the tax on gasoline used for purposes other than to generate power for transportation over highways. More discussion of this plan of taxation might lead to a solution of some difficulties.

CANADA'S FUEL PROBLEM

THERE is no necessity for Canada, with her vast resources of fuel and water-power, to go cold or to have her industries throttled by shortage of power, but Canada may have a sore trial in both these respects unless every possible effort is made to deal with the fuel and power situation in a comprehensive manner, writes Arthur V. White, consulting engineer of the Commission of Conservation, in the last issue of the "General Electric Review," published by the General Electric Co., of Schenectady, N.Y. Mr. White's article, "Canada's Fuel Problem—Some National and International Aspects," was reprinted in full in last week's issue of *The Canadian Engineer*, on account of the vital interest to Canada of his subject, and the broad and statesmanlike manner in which he deals with it.

The fuel problem of Canada must be solved by the engineers of Canada. It cannot be left entirely to politicians or financiers. Their help is needed, but the way must be and is being pointed out by Arthur V. White, R. A. Ross, C. A. Magrath, B. F. Haanel, James White, J. B. Challies, H. G. Acres, John Murphy, Arthur A. Cole, and a score of other prominent engineers who have specially studied the problem and who realize, better than any other group of men in Canada, the steps needed for its solution.

Mr. White's article was the twenty-eighth in a series on the more efficient utilization of America's fuel resources that is appearing, one article each month, in the interesting and well-edited "house-organ" of the General Electric Co. This series of articles forms a very important contribution to the existing literature upon the subject, and no doubt has been followed with interest by many of those engineers who have recognized the importance of the problems discussed.

Letter to the Editor

PRESENT SYSTEM IS CONVENIENT

Sir,—In connection with the present attempt to introduce the metric system into North America, attention is called to an apparently unobserved connection between length, volume and weight contained in our system.

The American railway usage of a 100 ft. chain, with the foot divided into tenths, hundredths and thousandths, is the only decimal system applicable to office, shop and field. The meter (almost 3.3 ft.) is too long for the office, and its next division, the decimeter (4 ins.), is too short for office use. A 20-meter chain (almost 66 ft.) is, like the Gunter chain, too short for railway work, and in levelling it is difficult to catch which meter is being read on the rod when close up.

The foot furnishes a remarkable relationship between volume and weight through the fact that a cubic foot contains 1,000 cubic tenths and a cubic foot of water weighs 1,000 ounces (62.5 lbs.). Thus a cubic tenth holds a fluid ounce of standard water, which weighs an ounce.

To apply this, imagine a box 1.5 tenths (0.15 ft.) by 1.5 tenths (0.15 ft.) by 2.7 tenths (0.27 ft.) long. It contains 6.075 cubic tenths (0.006075 cu. ft.) and will hold 6.075 fluid ounces of standard water, weighing 6.075 ounces av.

It would be possible to obtain a much better international measure by dividing a meter into three parts, calling each a metric foot (almost 1.1 ft.). This metric foot could be divided in tenths and the cubic tenth would weigh a metric ounce and hold a fluid metric ounce. One cubic metric foot, weighing 81.749 lbs. av., could be taken to contain ten metric gallons and to weigh 100 metric lbs. Each metric pound would contain 10 metric ounces. The "Canadian Magazine" published an article on this subject by the writer about 1895.

C. R. COUTLEE.

Ottawa, Ont., July 22nd, 1919.

PERSONALS

Major Alan Mair Jackson, who was recently appointed engineer of Brant County, Ont., was born in 1879, in New Zealand. He was educated at Dunedin High School and Otaga University, and served as an apprentice for six years in a foundry and machine shop, much of this time being spent in the erection of machinery. Major Jackson then became assistant engineer on drainage and sewerage in the city of Dunedin. Afterwards he served for six months as supernumerary engineer on a cargo tramp steamer, but left same upon its arrival at England. In 1905 he was sent to British Guiana to erect a gold dredge and to run a survey of a large gold dredging concession in the jungle. Subsequently he joined the Barima Gold Mining Co., in Demerara, on the border of Venezuela, where he erected all the company's machinery and built several miles of light railway. After four years in Demerara, Major Jackson returned to England in 1909, and early the following year came to Canada, where he spent a year in the mechanical department of the Canada Foundry Co., and then started a small engineering practice in Dunville, Ont. In 1912 he passed the O.L.S. examinations and became engineer for Haldimand County. The following year he moved to Brantford, Ont., and purchased the surveying and consulting practice of Howard Fairchild. In March, 1916, he enlisted as a captain in the 215th Battalion, but was soon promoted to the rank of major. He reverted to a captaincy upon his transfer to the 257th Railway Construction Battalion, with which unit he went to France. This battalion later became the 7th Battalion of Canadian Railway Troops. In France he was again promoted to the rank of major, and was in command of a company of the 7th Battalion for twenty-two months. In April, 1919, he returned to Brantford, and was appointed county engineer when construction work under the Ontario Highway Act was commenced by Brant County.

G. A. Kent, of Vancouver, gave an illustrated lecture recently before the Vancouver Board of Trade on a proposed extension of the Pacific Highway via Vancouver, Squamish and Lillooet, describing the scienic advantages of the route and the water power, timber and other natural resources that would be made available.

Sir Donald Mann, who is visiting British Columbia, has given an interview to the press in which he states that he is through with railroad construction. This is Sir Donald's first trip to the Pacific coast over the Grand Trunk Pacific Railway. He is very enthusiastic about the prospects of the interior of British Columbia.

Frank S. Easton, hydro-electric engineer with the British Columbia Electric Railway Co., Vancouver, has resigned to enter the employ of the Mexican Light & Power Co., with headquarters in Mexico City. Mr. Easton will have charge of certain hydraulic and electrical work for the company, under the direction of G. R. G. Conway, managing-director, who was formerly chief engineer of the British Columbia Electric Railway Co.

TNT AS A BLASTING EXPLOSIVE

(Continued from page 172)

each lateral root and one under the top root. The stump was broken into two about equal sized pieces which were thrown 35 and 65 ft. respectively from their original position. A crater 12 ft. in diameter and 4 ft. deep was formed. This shot was evidently overloaded.

Test No. 4—Stump Blasting.—An oak stump 3 ft. in diameter rooted in clay and sandstone fragments was removed by the use of eight ¾-pound charges, six being placed under the lateral roots and two under the centre. The stump was broken into four pieces, two large and two small. The large pieces were overturned at the edge of the crater, one small piece remained loose in the ground and the other was thrown about 75 ft.

In connection with this test, it is important to call attention to the fact that the charges were loaded in wet holes for a period of 1½ hours.

Test No. 5—Stump Blasting.—An oak stump 18 inches in diameter, rooted in clay was removed by a single 2-pound charge of grade 3 TNT placed under the centre of the stump. The stump was broken into two pieces and overturned at the edge of the crater.

Test No. 6—Stump Blasting.—A solid oak stump 3 ft. in diameter, rooted in clay was removed by four 1¾-pound charges placed under the lateral roots. The stump was split into three large pieces which were lifted about 10 ft. in the air and fell back into the crater.

Test No. 7—Log Splitting.—A solid oak log 6 ft. long, and 39 ins. diameter, was split into two separate pieces of practically the same size by 4 ounces of grade 3 TNT, loaded in a 2-inch hole located midway between the ends and about 2 inches beyond the centre of the log.

Test No. 8—Log Splitting.—A solid oak log, 6 ft. long, 44 ins. diameter at one end and 40 inches at the other, was split into two separate pieces of practically the same size by 5 ounces of grade 3 TNT, loaded as in Test 7.

Test No. 9—Wet Boreholes.—As the ability to use an explosive under water in very wet boreholes is of great importance, the following test was carried out: A borehole 1½ inches in diameter and 42 inches in depth was drilled vertically in the floor of a coal mine, through coal, limestone and fireclay. The top of the borehole was 4 ins. under water. As the maximum effect was sought, the borehole was overloaded with 2 pounds of grade 3 TNT, the explosive being pressed in sufficiently hard to break up the cartridges. No tamping was used. After a wait of 15 minutes, the charge was fired. A crater 4 ft. in diameter and 42 ins. deep was formed and considerable other material about the crater was so loosened as to be easily removed by a pick.

Conclusions

1. Grade 3 TNT can be successfully used for adobe shots of boulders, for removing stumps and for splitting logs.
2. Grade 3 TNT has shown itself to give results the equal of 40% straight nitro-glycerin dynamite.
3. Grade 3 TNT detonates completely with a No. 8 electric detonator.
4. The evidences of black smoke is not to be taken as an incomplete detonation.
5. Grade 3 TNT detonates completely under water.
6. Grade 3 TNT detonates completely after moderate immersion in wet holes.

ORDER YOUR BOOKS NOW

OWING to the great advance in the prices of paper, printing and binding, John Wiley & Sons, Inc., the well-known publishers, have found themselves compelled to increase the retail prices of a number of their publications, the advance to take effect August 20th. The prices of twenty-three of their leading books are being advanced by from 25c. to $1.00 per volume.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

BRIDGES, ROADS AND STREETS

Amherstburg, Ont.—Sealed tenders will be received until 8 p.m., July 28th, for the construction of Silex stone walks on the following streets: St. Arnaud; Laird; Alma and William. W. A. McCormick, town clerk.

Burlington, Ont.—The work on the Burlington end of the Beach road is progressing rapidly, one-half of the road to be completed before work on the other half is commenced. A permanent base is being laid.

Bury, Que.—Contract for reinforced concrete bridge has been awarded to S. J. Davies, Bury. Tender price, $1,448.

Bury, Que.—Following tenders for 7½ miles Beauceville-Sherbrooke Road were received by the Department of Roads, Quebec: Howick Paving Co., New York, $77,803.68; J. H. Worby, Bury, Que., $60,994.12; R. E. & J. L. Willard, E. Angus, Que., $65,000; Loomis Dakin Construction Co., Sherbrooke, Que., $57,008.73. Edgar Irvine and Deoits Bros., Montreal, $56,758. No contract has as yet been awarded.

Charlesbourg, Ont.—Tenders will soon be called for construction of concrete highway on St. Joseph's road. M. Henry, engineer, department of roads, Quebec.

Edmonton, Alta.—New plans for extensive road work in different parts of the province will be made by the government when the federal grant for highway improvement comes through. Alberta, in common with the other provinces, is due for a first instalment of $80,000.

Edmundston, N.B.—The Dominion Government has made an appropriation of $25,000 for erection of bridge over St. John River.

Gladstone, Man.—Contract for two pile bridges over White Mud River, in the municipality of Westbourne, has been awarded to A. Power, 249 River Ave., Fort Rouge, Winnipeg, Man. Tender price, $4,322.55.

Gloucester, Ont.—The township council is receiving tenders for 7,245 lineal feet of granolithic sidewalks.

Halifax, N.S.—Canadian National Railways, Moncton, N.B., have awarded contract for the construction of the Tantramar River bridge to the Nova Scotia Construction Co., Ltd., Halifax.

Halifax, N.S.—Contract for Bedford Road has been awarded by the highway board to the Barrett Co. Tender prices, earth excavation, $1.50 per cu. yd.; rock excavation, $3.00 per cu. yd.; paving, $1.60 per sq. yd.

Halifax, N.S.—The city department of works has awarded contracts for street paving totalling $800,000.

Hope, B.C.—A trans-provincial highway is proposed between Hope and Princeton. Construction of about 100 miles of road is involved.

Kenogami, Que.—Tenders will soon be called by the municipal council for pavements costing about $15,000. Chas. Lightwood, clerk.

Kingston, Ont.—Contract awarded by the department of public works, Dominion government, to John F. Sowards, Kingston, for placing stone rip-rap along Lasalle Highway.

Kingston, Ont.—Tenders for asphalt concrete roads were considered too high by the board of works. Three tenders were received, ranging from $4 to $4.05 per sq. yd. As the city engineering department is doing the same paving at the present time for $2.10 a sq. yd., the board decided that this work should be done by day labor.

TOWNSHIP OF YORK

CONSTRUCTION OF WATER MAINS

Sealed tenders, plainly marked as to the contents, will be received by the undersigned engineer for the Municipal Corporation of the Township of York up to 10 o'clock a.m., Tuesday, August 5th, 1919, for the construction of 6-inch cast-iron water mains in the following streets in the Township of York:—

1. Atlas Ave. North (1,124 ft.).
2. Hanson Road, Rockvale Ave., Clovelly Ave., Strader Ave. (2,840 ft.).
3. Miller Ave., Northcliffe Blvd., Westmount Ave. (1,940 ft.).
4. Robina Ave., Cedric Ave., Holland Park Ave., Wilmington Ave. (4,460 ft.).
5. Tay Ave., Glanville Ave., Rushton Road, Durham Ave. (3,370 ft.).
6. Bernice Ave., Eileen Ave., Mildred Ave., Lyndon Ave., Elvin Ave., Scarlett Road (7,190 ft.).
7. Florence Cres., White Ave., Brooke Ave., Pritchard Ave., Jane St. (4,200 ft.).
8. Thornhill Ave., Priscilla Ave., Windermere Ave., Brookside Ave., Bradley Ave. (7,530 ft.).

Plans and specifications and all necessary information may be obtained at the office of the Engineer, Frank Barber, 40 Jarvis Street, Toronto.

The lowest or any tender will not necessarily be accepted.

FRANK BARBER,
Engineer.

Toronto, July 14th, 1919. 298

Kipling, Sask.—Tenders will be received until noon, July 28th, by H. A. Dixon, chief engineer, Can. Nat. Rys., Winnipeg, Man., for the construction of three reinforced concrete culverts, Mile 142 to Mile 173, Kipling Subdivision. Plans, specifications, instructions to bidders and form of tender can be obtained at the offices of the chief engineer, Winnipeg; superintendent, Brandon; district engineer, Saskatoon, and freight agent, Regina.

Kitchener, Ont.—The county council has awarded contract for three miles of road to Lichty Bros., Wellesley. Tender price for sections, St. Jacobs, $1,942.40; Wellesley, $3,780; Woolwich, $42,659.20. The St. Jacob's section will be 14 feet wide, an area of 12,600 square feet. The Wellesley section will be 20 feet wide and area of 21,000 square feet, and the Woolwich section will be 16 feet wide and area of 28,160 square yards.

Lancaster, Ont.—Town council will soon call for tenders for construction of sidewalks. Estimated cost, $10,000.

Lanigan, Sask.—The C.P.R. Co. has awarded contract for two bridges to C. Anderson and A. J. Creelman.

L'Assomption, Que.—The following tenders have been received for bridge between Repentigny and Charlemagne by the county council. The award will not be made before August 11th: Superstructure, Phœnix Bridge and Iron Works, Ltd., $41,295; Mackinnon Steel Co., Ltd., $33,950. Substructure, Nicolet Construction Co., Ltd., $34,689; J. A. Brouillet, L'Assomption, $31,530.

Markham, Ont.—Tenders will be received until noon, August 2nd, by G. A. Davidson, township clerk, for three concrete bridges. Plans and specifications may be seen at the clerk's office or at the office of the engineers, James, Loudon and Hertzberg, Ltd., 36 Toronto St., Toronto.

Montreal, Que.—Tenders will be received by the Administrative Commission, city hall, until noon, July 28th, for the demolition of the old, and the construction of a new wooden bridge over the aqueduct at Woodland Ave. Rene Bauset, city clerk.

Montreal, Que.—Tenders will be received until noon, July 29th, by the Administrative Commission, city hall, for construction of a block and asphaltic composition pavement on Redpath St., from Sherbrooke St. to the north limits. Rene Bauset, city clerk.

Nanaimo, B.C.—It is proposed to extend the Island highway, twenty-two miles from Campbell River, to open up the Sayward Valley for settlement. Mr. Stewart, M.P.P., for Comox district.

Newmarket, Ont.—The town council has awarded the contract for reconstruction of the Prospect Street bridge, recently washed out, to the Lewis Construction Co., Toronto.

Ormstown, Que.—The municipal council will soon call for tenders for about 9 miles of road work.

Repentigny, Que.—Tenders will soon be called by the municipal council for construction of bridge.

St. Antoine, Que.—Tenders are being received by the municipal council for waterbound macadam highway.

St. David, Que.—The municipal council has awarded contract for bridge to The Nicolet Construction Co., Nicolet, Que.

St. Placide, Que.—Tenders will soon be called by the village council for road work.

Victoria, B.C.—Plans have been approved for steel bridge of Bascule type by the provincial government and C.P.R. Co.

Winnipeg, Man.—Plans have been prepared for Maryland bridge. It will consist of three spans of 150 feet each, with double street car tracks.

WATER, SEWAGE AND REFUSE

Amherstburg, Ont.—Walter Mann has been awarded contract for sewer at $1,098.97.

Brandon, Man.—Contract for two motor-driven centrifugal pumps for Hospital for Insane has been let by the Provincial government to The Goldie & McCulloch Co., Ltd., Galt, Ont., for $2,940.

Cochrane, Ont.—Extension to waterworks system is contemplated by the town council. Clerk, H. J. Brown.

Drumbo, Ont.—Tenders will be received by Hugh Allan, township clerk, Drumbo, until noon, July 26th, for the construction of the lower portion of the Bremner Creek drain, in the 4th concession of the township of Blenheim. Plans and specifications may be seen at the clerk's office, Drumbo.

Kingston, Ont.—The department of public works, Ottawa, has awarded contract for sewerage system and disposal works, Sydenham Convalescent Hospital, to W. H. Harvey, Kingston. Contract price, $10,403.50.

Kitchener, Ont.—The water supply of the city of Kitchener has decreased in volume lately owing to a shortage in pumping capacity. It is understood that the Water Commission will instal a new compressor shortly to augment the supply derived from wells.

Lethbridge, Alta.—The city council plans installation of meters for water. Estimated cost, $35,000.

Montreal, Que.—Contract for the construction of a sewer in Plamondon St. and Decarie Blvd. was awarded to A. T. A. Chagnon & Co. for $7,171.

Montreal, Que.—Tenders for sewers on Plamondon St. and Decarie Blvd. were received from the following firms at prices mentioned: DeKeyser Wauters Cie, $8,360; Filion and Frères, Ltée, $7,892; Chas. G. Craib, $8,332; J. Ricci and J. Désautels, $9,220.50; Léopold Toussaint, $12,372.50; The Federal Engineering and Constructing Co., Ltd., $8,835; D. Vocisano, $7,343; John Quinlan and Co., $12,439; Atlas Construction Co., Ltd., $9,906; Joseph Rondou, $8,184.75; A. T. A. Chagnon and Cie, $7,171; O. Filion, $9,130; E. T. Verbanise, $8,567; city of Montreal, $9,987.

Newmarket, Ont.—Sealed tenders will be received until noon, August 7th, for the construction of storm and sanitary sewers. (Official advertisement in this issue.) Town clerk, P. J. Anderson. Engineers, James, Loudon & Hertzberg, Ltd., Toronto.

Newmarket, Ont.—Tenders, sealed and marked, will be received by P J. Anderson, town clerk, up to noon, August 7th, for the construction of storm and sanitary sewers. Plans and specifications may be seen at the office of the engineers, James, Loudon & Hertzberg, Ltd., 36 Toronto St., Toronto, or at the office of the clerk, Newmarket.

North Bay, Ont.—Sealed tenders will be received until 12 o'clock noon, August 2nd, for the construction of sewers on the followning streets: Cassels St., from Worthington to First Ave.; McIntyre St., from a point west of Bell St., 170 ft.; Bloem St., from Klock Ave., 250 ft. westerly; Worthington St., from Sherbrooke to Wyld St. H. J. McAuslan, town engineer.

Ottawa, Ont.—The city council will soon call for tenders for drainage system for Holland Ave district. Estimated cost, $38,000.

Peterborough, Ont.—Erection of a filtration plant is contemplated by the city council. Estimated cost, $200,000. W. H. Moore, Utilities Commission.

Point Grey, B.C.—Plans are being prepared for sewerage system for the Vancouver and District Sewerage and Drainage Board.

Saanich, B.C.—The municipal council, Royal Oak, contemplates construction of sewerage system to include Cloverdale and Gorge districts.

Sandwich, Ont.—Tenders have been awarded by the town council for sewers and paving for a total cost of $85,000. Sewers will be constructed on Huron Line, Brock St. and Josie Ave., and paving will be laid on Centre Rd. The sewers will cost $70,000, while the paving will cost $15,000.

Vermilion, Alta.—The town council contemplates construction of fire tanks of 30,000 gallons capacity.

Barrett Specification Roof on Plant of Tabor Ice Cream Co. Architect: C. D. Cooley Co. Roofer: Lee H. Gould & Co. Gen. Contrs.: The Reaugh Con. Co.
Barrett Specification Roofs

The roof on this plant is soaking wet 24 hours a day, 365 days in the year!

Can you imagine a more severe test than to have a *perpetual shower falling on a roof every day and night year in and year out?*

This is what happens to the Barrett Specification Roof on the Tabor Ice Cream Co. plant illustrated above.

This shower comes from the big water-cooler on top of the structure which is used for cooling the ammonia.

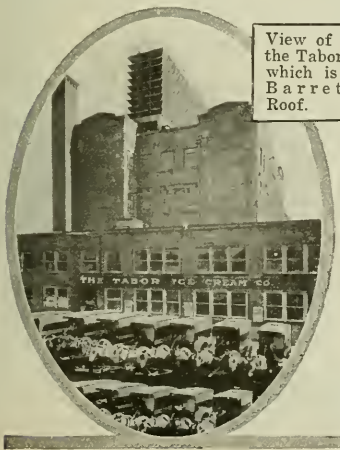
No ordinary roof would stand up under such conditions.

And that is why the Tabor Ice Cream Co. had its million-dollar plant protected with a Barrett Specification Roof.

Even such a severe test has no terrors for a Barrett Specification Roof because it is planned to meet just such extreme conditions.

No other roof contains as much protective waterproofing material in its construction, and that is the reason these roofs give such long and satisfactory service.

Not only do Barrett Specification Roofs last longer than others, but they *cost less per year of service;* they take the base rate of insurance and *carry a 20-Year Surety Bond Guaranty.*



View of the building of the Tabor Ice Cream Co., which is roofed with a Barrett Specification Roof.

20-Year Guaranty

We now guarantee Barrett Specification Roofs to last for twenty years without cost for maintenance. No charge for the guaranty, for it gives us a chance to protect the good repute of these roofs. The guaranty is a Surety Bond issued by one of the largest surety companies in the world. It is offered on all roofs of fifty squares and over in all cities of 25,000 population and more, *and in smaller places also where our Inspection Service is available.*

A copy of the Barrett 20-Year Specification, with roofing diagrams, sent free on request.

The Barrett Company LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER
ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

Waterford, Ont.—The town council has decided to instal waterworks system. W. S. Fuller, clerk.

Windsor, Ont.—Plans have been prepared for $100,000 pumping station and filtration plant for seven border municipalities.

York Township, Ont.—Contracts have been awarded for laying of 6-in. water mains on Burton St., to McKnight Construction Co., Toronto, $4,064.54. Rejected tenders, Murphy Construction Co., $4,633.17; Angelo Cavoti, $5,390.29; on Graham Ave., to Angelo Cavoti, $2,302.78. Rejected tenders, Murphy Construction Co., $2,575.85; McKnight Construction Co., $2,648.85. Frank Barber and R. O. Wynne Roberts, engineers.

LIGHT, HEAT AND POWER

Amherst, N.S.—The Canada Electric Co., Ltd., will increase power capacity.

Barnet, B.C.—The British Columbia Electric Ry. Co., Vancouver, has had plans prepared for transformer station.

Camrose, Alta.—By-law has been passed authorizing expenditure by the town council for power plant.

Galetta, Ont.—The Galetta Power and Milling Co. contemplates construction of extensions to transmission line.

Naramata, B.C.—Contract for power house has been awarded by the town council to J. Winger, Peachland, B.C.

Ottawa, Ont.—Contract for electric fixures and lamps in the Hunter Building has been awarded by the department of public works, Dominion government, to A. A. Giddings & Co., Montreal.

Portage la Prairie, Man.—Contracts have been let by the department of works, Winnipeg, for the construction of the Portage Power Transmission lines as follows: Galvanized steel towers, Canadian Bridge Co., Walkerville, Ont., $96,160; construction work, W. J. Holmes, $46,000; aluminum steel conductor, Northern Aluminum Co., Toronto, $34,123; insulators, Canadian Porcelain Co., Hamilton, Ont., $30,000; galvanized steel cable guy wires, Northern Electric Co., Winnipeg, Man., $9,000; transformers, Canadian General Electric Co., Winnipeg, $22,600. Hon. George Grierson, Winnipeg.

Regina, Sask.—Tenders for the supply of power and light extension material has been awarded by the commissioners as follows: Moloney Electric Co., Toronto, $5,722; Parkard Electric Co., Winnipeg, $4,675; Canadian General Electric, $3,112; Lyman Tube & Supply Co., Winnipeg, $378.40; Northern Electric Co., $306; Dawson & Co., Montreal, $271.60; Northern Electric Co., $228.

Saskatoon, Sask.—Sealed tenders, endorsed "Turbo Generator," will be received by C. J. Yorath, city commissioner, up to noon on Tuesday, September 23rd, 1919, for the following: First contract—One steam turbine, one alternating current generator and switchgear equipment. Second contract—One surface condenser and condenser auxiliaries. Forms of tender, etc., may be obtained upon application to the city commissioner.

Saskville, N.B.—The Eastern Electric and Development Co., Ltd., contemplates further development.

St. Raphael, Que.—Gauvin & Lessard, engineers, 147 Cote de la Montagne, Quebec, have completed plans and specifications for a water power development here (Bellechasse County), and are in the market for two water wheels of 1,100 h.p. each; head, 245 ft. Also two generators; exciters; switchboards; one penstock, 8,020 ft. long; one head gate; and construction of transmission line, 16 miles, 3-phase, 55,000 volts. La Corporation Electrique de Montmagny, owner.

St. Stephen, N.B.—L. H. Whealen, Halifax, has prepared plans for additions to plant for the St. Stephen Electric Light Co.

Sutherland, Sask.—Sealed tenders will be received until 12 o'clock noon, Tuesday, August 5th, by the department of public works, Ottawa, for an automatic lighting plant, wiring, fixtures and pole line, Forest Nursery station. Plans and specifications may be obtained from the chief architect, Ottawa; clerk of works, Regina, and caretaker, public building, Saskatoon, Sask. R. C. Desrochers, secretary.

Vancouver, B.C.—The Western Power Co. of Canada, Vancouver, contemplates extensive water power development.

Vernon, B.C.—The municipalities between Kamloops, B.C., and Kelowna, B.C., will petition the government to develop sufficient electrical energy from the Adams River and Shuswap Falls to supply power to the Shuswap and Okanagan valleys, and to electrify the Okanagan branch of the Canadian Pacific Railway.

Wiarton, Ont.—The Sauble Falls Light Co., Wiarton, Ont., plans development of power.

RAILWAYS

Fredericton, N.B.—The St. John Valley Railway will be completed by the contractors so as to be handed over to the Dominion government for operation as part of the Canadian National Railways before August 1st. Hon. W. P. Jones, president of the St. John and Quebec Railway Co. and representative of the New Brunswick government in the construction.

Guelph, Ont.—Extension of the Toronto Suburban Railway from Guelph to Kitchener, Stratford and London, and perhaps on to Windsor or Sarnia, as one of the links of the new Canadian National Railways system is planned by the Dominion government.

Halifax, N.S.—The Nova Scotia Tramways Co. will undertake extensive track renewals; construction of additional cars; extension of lines, and will increase the present equipment of their power stations. Estimated cost, $1,000,000.

Montreal, Que.—The electrification of the railway of the Montreal Harbor Commission will likely be commenced this month, to be completed late in the fall.

Owen Sound, Ont.—W. F. Tye, Montreal, has been instructed to prepare plans on the interswitching problem.

Sarnia, Ont.—The city council contemplates street railway extensions.

Toronto, Ont.—Plans will be prepared and tenders will soon be called by the Ontario Railway Board for construction of a temporary electric railway on Mount Pleasant Rd. Estimated cost, $1,142,294.

Victoria, B.C.—Eighteen miles of grading on the Pacific Great Eastern Railway is now complete, and arrangements are being made to commence track-laying towards Williams Lake at the rate of one and a half miles per day. Ballasting and surfacing operations are proceeding satisfactorily, and the foundation work for Deep Creek bridge is under way.

Weston, Ont.—Several switches will be constructed on the radial line between Toronto and Weston by the Canadian National Railways.

Winnipeg, Man.—The Canadian Pacific Railway Co. have awarded contracts covering construction of more than 200 miles of line. The John Stewart Construction Co., Vancouver, will construct the lines from Mildend, to Empress, 34 miles; from Consul to Assiniboia, 30 miles; from Lanigan to Carrot River, 50 miles, and from Rymark to Archive, 50 miles—all in Saskatchewan. The Canadian Construction Co., Winnipeg, will construct from Rosetown, Sask., south, 25 miles. The Northern Construction Co. will construct from Russell, Sask., 12 miles north. D. C. Coleman, vice-president.

FACTORIES AND LARGE BUILDINGS

Arnprior, Ont.—The Arnprior Cabinet Co., Ltd., will erect large addition to factory. R. J. Simpson, vice-president and general manager.

Belleville, Ont.—New fire hall will be erected at entrance to Victoria Park.

Beynon, Alta.—Tenders will be received until noon, August 1st by the board of trustees, school district No. 3811, for

Burlington Steel Co., Ltd.
Hamilton, Canada

STEEL BARS
For
Concrete Reinforcing

THE MOST IMPORTANT FACTOR IN CONCRETE REINFORCEMENT IS THE TENSILE STRENGTH AND ELASTIC LIMIT OF THE REINFORCING BAR.

OTHER THINGS BEING EQUAL, STEEL HAVING THE HIGHEST ELASTIC LIMIT, OR YIELD POINT, WILL BE THE MOST SATISFACTORY FOR REINFORCEMENT. WHEN UNDER STRAIN, AS SOON AS THE ELASTIC LIMIT OF ANY REINFORCING BAR IS REACHED, THE METAL STRETCHES RAPIDLY DECREASING IN SECTION, DRAWING LOOSE FROM THE CONCRETE AND DESTROYING THE MONOLITHIC BOND EXISTING BEFORE THIS POINT IS REACHED THEREFORE, THE SAFETY OF THE ENTIRE CONSTRUCTION IS IN DIRECT PROPORTION TO THE ELASTIC LIMIT OF THE STEEL USED.

THE ELASTIC LIMIT OF RAIL CARBON STEEL IS 50,000 TO 60,000 POUNDS PER SQUARE INCH, EITHER TWISTED OR PLAIN, AS COMPARED WITH AN ELASTIC LIMIT OF 25,000 TO 30,000 POUNDS IN SOFT STEEL.

THAT'S WHY RAIL CARBON STEEL, WITH ITS 80,000 POUNDS MINIMUM TENSILE STRENGTH, IS RECOMMENDED AS BEING FAR SUPERIOR FOR ALL KINDS OF REINFORCED CONCRETE WORK.

AT OUR HAMILTON, ONT., WORKS WE BUY SELECT RAILS, AND ROLL THEM INTO RAIL CARBON STEEL REINFORCING BARS IN A PLANT WHICH IS THE EMBODIMENT OF THE LATEST THOUGHT AND PRACTICE.

THESE BARS CAN BE SUPPLIED FROM STOCK IN VARIOUS SIZES, LENGTHS AND SHAPES. WE CAN ALSO ROLL SPECIAL SHAPES AND SIZES TO FIT YOUR PARTICULAR REQUIREMENTS.

Bars bent to shape for Beams, Stirrups, Etc.

PROMPT SHIPMENT

the erection of a new frame building. F. J. Kelly, secretary-treasurer.

Brandon, Man.—Tenders will be received until 12 o'clock noon, July 29th, by the commissioner of the R.N.W.M.P., Regina, Sask., for the construction of new barracks. Architect, H. E. Matthews, 802 Lindsay Building, Winnipeg, Man. A. B. Perry, commissioner, Regina.

Burnaby, B.C.—The Alexander Cunningham & Gregory Tire & Rubber Co., care Imperial Oil, Vancouver, contemplates erection of rubber plant, and have applied to the Burnaby council for certain concessions.

Calgary, Alta.—According to A. W. Dingman, managing director of the Calgary Petroleum Products Co., the enlarged gasoline extraction plant which is now being installed by the Hope Engineering & Construction Co. at the No. 1 and No. 2 wells of the oil concern in the Black Diamond field, will start operating soon. The new plant's rated capacity is the treatment of 6,000,000 cubic feet of wet gas per 24 hours.

Camrose, Alta.—The Continental Oil Co. plans to build warehouse.

Canford Mills, B.C.—Lumber mills, sawmills, planing mills, etc., recently destroyed by fire, will be re-erected by the Canford Mills Co.

Chicoutimi, Que.—Sealed tenders will be received until 12 o'clock noon, August 9th, by the Canadian National Railways, for the erection of a station building. Plans, etc., may be obtained from the district engineer, Champlain Market, Quebec, Que., and Tunnel Terminal Station Building, Montreal, Que. A. F. Stewart, chief engineer, Toronto.

Collingwood, Ont.—The Gregory Tire & Rubber Co. will erect factory here.

Davidson, Sask.—The Davidson Co-operative Association contemplates addition to warehouse.

Duck Lake, Sask.—The erection of a grain elevator is planned by the North Star Elevator Co.

Dundas, Ont.—W. H. Yates, Hamilton, Ont., has been awarded contract for addition to public school. Tender price, $60,516. Work has commenced and contract calls for its completion by October 15th.

Essex, Ont.—Tenders will be received by E. L. Park, chairman building committee, Essex, Ont., until noon, July 28th, for alterations and additions to the I.O.O.F. building. Plans and specifications can be seen at the office of J. C. Pennington, architect, 35 LaBelle Building, Windsor, or at William Chatterton's store, Essex.

Fort Qu'Appelle, Sask.—Plans have been prepared for skating rink to be erected by town council.

Glace Bay, N.S.—Tenders will be received until August 1st for the laying of a new floor and other repairs to the Alexandra Rink. James A. Campbell.

Grosse Isle, Que.—The department of public works, Ottawa, has awarded contract for construction of operating house, Radiotelegraph station, to Delphe Maranda, Que. Contract price, $2,340.

Halifax, N.S.—Contract for train shed, Halifax Ocean Terminals, has been awarded to James Shearer Co., Ltd., Montreal.

Halifax, N.S.—The Nova Scotia Tramway & Power Co., Ltd., contemplates extensions to plant.

Hamilton, Ont.—The department of public works, Ottawa, has awarded contract for construction of Postal Station "B" to Kennedy Connor, Hamilton. Contract price, $36,650.

Hanover, Ont.—The Portland Cement Co. contemplates remodelling plant.

Harrow, Ont.—The John V. Grey Construction Co., Toronto, have been awarded contract for warehouse by W. Clarke, Ltd., 83 Amherst St., Montreal.

Hull, Que.—The department of agriculture, Ottawa, has awarded contract for construction of cattle barn at the Research Station, Health of Animals branch, Hull, Que., to Doran & Devlin, Ottawa. Contract price, $5,380.

Kingston, Ont.—The city council has decided that tenders submitted for new school were too high. A resolution has been passed recommending to the board of education that new tenders be called about November 15th, and that stone as well as brick be specified. The school is to consist of ten rooms. Estimated cost, $135,000.

Kingston, Ont.—The department of public works has awarded contract for nurses' home at Mowat Sanatorium to McKelvey & Berch, Ltd., Kingston.

Kitchener, Ont.—The F. W. D. Auto Co. will commence construction of their new factory in the east end of the city as soon as they received definite information on the new location of the Grand River Railway. J. Cotton, Clintonville.

Ladner, B.C.—The Bank of Montreal is erecting a building in this town.

Montreal, Que.—Tenders will be received until noon, August 4th, by the Marcil Trust Co., for the construction of an office building on St. James St., opposite Victoria Sq. Architect, Hogle and Davis, 80 St. Francois Xavier St., Montreal.

Oakville, Ont.—Town council has approved the expenditure by the board of education of $22,000 for new school building.

Petrolea, Ont.—Tenders will be received until August 7th, by the board of governors of the Charlotte Eleanor Englehart hospital for the construction of a nurses' home. Architect, Isaac Erb, Port Huron. Wm. Pratt, secretary, Masonic Temple, Petrolea, Ont.

Picton, Ont.—A new factory will be built by Kinney and Colliver on Barker St.

Portage la Prairie, Man.—Tenders will soon be called for enlarging public building. Estimated cost, $25,000.

Port Arthur, Ont.—The Barnett & McQueen Co. here have been awarded contract by the department of public works for new workhouse at the Canadian National elevator. The elevator workhouse will have a capacity of 700,000 bushels, and will be constructed of reinforced concrete. An electric sub-station will be erected to operate the plant.

Red Mill, Que.—The Canada Paint Co., 572 William St., Montreal, will erect factory here.

Regina, Sask.—The Capital Broom Manufacturing Co. will erect three new buildings on lots Nos. 11 and 12, block No. 23, eastern annex. Estimated cost, approximately $7,500.

Regina, Sask.—Thos. Barnard has been awarded contract for new Duncan block, corner of Dewdney and Albert Streets. Tender price, about $30,000.

Rosser, Man.—Debentures will be issued to the amount of $18,000 for erection of school. W. H. Beachell, secretary-treasurer, Rosser, Man.

South Vancouver, B.C.—The Gregory Tire and Rubber Co. will erect their new factory on Euclid Ave. and Joyce Rd.

St. Boniface, Man.—Contract for materials for parish church has been given to the Canadian Investment Co. Moen Bros. have the contract for structural work.

St. Catharines, Ont.—Tenders will soon be called for extension to public building.

St. John, N.B.—Time for receiving tenders for the construction of a nurses' residence at the general public hospital has been extended to July 31st. Tenders to be addressed to Henry Hedden, M.D., secretary of the board of commisisoners. Plans and specifications may be seen at the office of the architect, F. Neil Brodie, 42 Princess St.

St. Thomas, Ont.—Site has been secured at Penafore Park for pavilion. Architect Darrach is preparing plans. Estimated cost, $8,000.

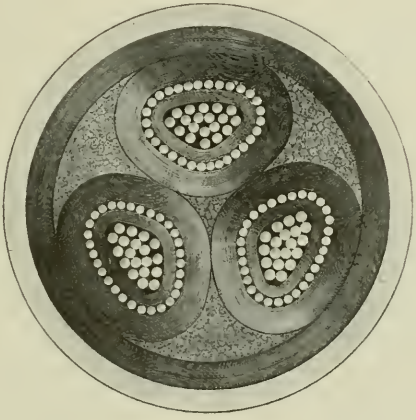
Sydney, N.S.—Contract for the construction of a coaling plant and sand-house has been let by the Canadian National Railways, Moncton, N.B., to Williams & Wilson, Ltd., Montreal.

Three Rivers, Que.—Telesphore Dugre, Three Rivers, has been awarded contract for theatre. Tender price, approximately $25,000.

Three Rivers, Que.—The Three Rivers Shipbuilding Co. plan erection of additional buildings soon.

Three Rivers, Que.—The Tidewater Shipbuilding Co. contemplates extensions at an approximate cost of $250,000.

SPLIT-CONDUCTOR CABLES



250,000 C.M. 3-CONDUCTOR 13,200 VOLT
PAPER-INSULATED, LEAD COVERED CABLE

Eugene F. Phillips Electrical Works, Ltd.

MONTREAL

Branches: Toronto, Winnipeg, Regina, Calgary, Vancouver

Toronto, Ont.—Separate tenders will be received until noon, August 1st, by A. F. Stewart, chief engineer, eastern lines, Canadian National Railways, 27 Wellington St. East, Toronto, for three section houses, two stations, five coal and oil houses, and 21 bunk houses. Plans and specifications may be seen at the office of Geo. C. Briggs, architect, 27 Wellington St. East, Toronto, and D. Couper's office, G.N.W. Telegraph Building, corner Sparks and Metcalfe St., Ottawa.

Toronto, Ont.—The following building permits have been granted by the city architect's department: C. G. Webby, brick apartment addition, 216 Avenue Rd., $8,000; W. Robertson, one pair semi-detached two-story brick dwellings, 49-51 Blackthorne Ave., $4,500; J. Taylor, two-story brick addition, 24 Ellerbeck Ave., $3,000; Wm. Watson, two-story brick dwelling, 113 Mackay Ave., $3,000; G. W. Edgar, to alter dwelling to duplex, 372 Annette St., $2,000; R. M. Sheppard, three two-story brick and frame dwellings, 111, 121, 139 Runnymede Rd., $10,800; Cox & Cummings, two-story brick and stucco dwelling, near McLean Ave., $4,500; Fred J. Cummings, 4 two-story brick and concrete stores, 2304-10 Queen St. E., $12,000; James Wilkins, one detached two-story brick, tile and stucco dwelling into private garage, 40 Oakmount, $8,000; Wm. Davies, one-story addition to brick house, 521 Front East, $6,000.

Toronto, Ont.—The new public library to serve the increasing demands of the Earlscourt district will soon be under construction. The new site will be on Dufferin St., south of St. Clair Ave.

Toronto, Ont.—Tenders will be received until noon, July 29th, by the York Township Housing Commission, 40 Jarvis St., for construction of brick houses in Oakwood, West Toronto, Mount Dennis, Forest Hill, Armour Heights, Swansea and Earlscourt districts.

Toronto, Ont.—$6,500 will be expended by the Imperial Extract Co., Don Improvement Roadway, on addition to factory.

Toronto, Ont.—Tenders will be received until July 28th, by board of education, W. C. Wilkinson, secretary-treasurer, for teachers' revolving chairs, pupils' desks and seats, heating and ventilating, new boilers, masonry work, plumbing, and electric wiring. Specifications may be seen and all information obtained at the office of the superintendent of buildings, 155 College St.

Toronto, Ont.—The Jefferson Glass Co. will erect factory at 388 Carlaw Ave. Estimated cost, $7,000.

Toronto, Ont.—The Blatchford Calf Meal Co., of Waukegan, Ill., is establishing a factory in Toronto, and will operate under the name of Blatchford Calf Meal Co. of Canada, Ltd. J. W. Barwell, president, Waukegan, Ill. Details regarding the Canadian plant are being arranged by the company's vice-presidents, W. L. Blows and H. C. Burnette, Waukegan, Ill.

Toronto, Ont.—Site has been purchased by the city for $123,150 on Bathurst St. for hospital for insane.

Truro, N.S.—The board of directors of the Truro Protestant Orphanage have decided to call for tenders for the demolition of part of the present buildings and construction of a new wing.

Winnipeg, Man.—It is estimated that about $2,000,000 will be expended this year on building between three and four thousand homes in this city.

Winnipeg, Man.—Tenders will be received by C. J. Brown, City Clerk, Winnipeg, until 3' p.m., July 28th, for the supply of all labor and materials required for the erection of a show room building for the city light and power department, on Princess St. Plans, specification and form of tender may be obtained at the office of J. J. Chisholm & Son, architects, 703 Great West Permanent Building.

Winnipeg, Man.—Tenders will be received by M. Peterson, secretary, committee on finance, city clerk's office, Winnipeg, Man., until 3 p.m., July 30th, for alterations and additions to the central market building, to convert same into civic offices. Plans and specifications and form of tender may be obtained at the office of the building inspector, corner James Ave. and King St.

MISCELLANEOUS

Buckingham, Que.—The department of public works, Ottawa, contemplates reconstruction of wharf.

Calgary, Alta.—Tenders will be received until July 31st for construction of concrete pier and circle wall for turntable. Canadian Pacific Railway station superintendent.

Chatham, Ont.—The city council has decided to purchase an asphalt paving plant to be used in repairing pavements. Estimated cost, $18,883.

Collingwood, Ont.—Construction of breakwater costing $50,000 is contemplated by the department of public works, Ottawa.

Eburne, B.C.—Improvements to bridges are contemplated by the provincial government. It is proposed to install electric lighting and motors to work main drawbridge.

Edmonton, Alta.—Contract for clear water basin has been awarded by the city commissioners to Swanson and Kaline.

Esquimalt, B.C.—The Dominion government engineers are taking the necessary borings preliminary to active construction on the new drydock. It is expected that construction work will soon be under way and rushed to completion. Engineer, Davy, Esquimalt, B.C.

Fairview, B.C.—The Provincial government has awarded the first contract to construct irrigation flumes and ditches in connection with the soldiers' land project in Southern Okanagan district to A. E. Griffen & Co., Vancouver.

Grosse Isle, Que.—Sealed tenders will be received until 12 o'clock noon, August 5th, by the department of public works for construction of an extension to the eastern wharf at Grosse Isle Quarantine Station. Plans, etc., may be obtained from the district engineer, Montmagny, Que.; postoffice, Quebec, Que., and the Shaughnessy building, Montreal, Que. R. C. Desrochers, secretary.

Kincardine, Ont.—The department of public works has awarded contract for dredging to The C. S. Boone Dredging and Construction Co., Ltd., Toronto.

Kingston, Ont.—The department of public works, Ottawa, has awarded contract for stone rip-rap along south walls of Lasalle highway to John F. Sowards, Kingston. Contract price, $7,950.

Laprairie, Que.—$82,000 will be expended by the department of public works for protection work.

New Massett, B.C.—The department of public works, Ottawa, has awarded contract for wharf to W. T. Muse, Prince Rupert, B.C.

North Battleford, Sask.—The citizens' committee contemplates erection of aerodrome.

Okanagan Centre, B.C.—The department of public works, Ottawa, will receive tenders until August 5th for construction of public wharf. R. C. Desrochers, secretary.

Ottawa, Ont.—Tenders will be received until 3 p.m., July 29th, by the board of control, city hall, Ottawa, for the construction of foundations and installation of a 20-ton weigh scales in the By Ward Market. Wm. Borthwick, market inspector.

Port Hope, Ont.—Contract for repairs to pier has been awarded by the department of public works to R. Brewder, Cobourg.

Powell River, B.C.—Tenders will be received until noon, July 31st, by R. C. Desrochers, secretary, department of public works, Ottawa, for the construction of an addition to the wharf and dredging at Powell River, District of Comox-Alberni, B.C. Plans and forms of contract can be seen and specification and forms of tender obtained at the department of public works; at the offices of the district engineers at Westminster, B.C.; Victoria, B.C.; at the post-offices, Vancouver, B.C., and Powell River, B.C.

Princess Creek, B.C.—Wharf costing about $7,000 will be constructed here by the department of public works.

"I have the help of eighteen of the best engineers in the country right with me every day."

So writes an engineer of

The American Highway Engineers' Handbook

ARTHUR H. BLANCHARD, Editor-in-Chief, and 17 Associate Editors.

As an engineer interested in highway work, you want the best reference book. You want quick, ready reference every day—your work demands that this information be available instantly—no time to search through the library—you must know at once. "Blanchard" tells you just what you want to know about highway engineering and related subjects.

This handbook answers every question that is likely to arise on highway work. Eighteen of the foremost men in engineering prepared this book—each chapter written by a specialist—each specialist knowing just what the engineer needs—what you need in your work.

Send to-day for your copy. The coupon below is for your convenience. To-day.

xxv. + 1658 pages. 4¼ x 7. Flexible binding, $5.00 net.

Modern Asphalt Pavement

By CLIFFORD RICHARDSON, Director New York Testing Laboratories. 2nd Edition, Revised and Enlarged.

Civil engineers, asphalt experts and specialists will find in this book a large collection of data regarding the chemistry of asphalt and the technology of the industry. Discusses the materials constituting the asphalt paving industry, handling of binder and surface mixture on the street, etc.

ix. + 629 pages, 6 x 9. 42 figures. Cloth, $3.00 net.

Street Pavements and Paving Materials

By GEORGE W. TILLSON, C.E., Mem. Am. Soc. C. E. 2nd Edition, Revised and Enlarged.

Here is a book for students, engineers and city officials. It is a manual of city pavements and covers the methods and materials of their construction. Includes cobble and stone block pavements, asphalt pavements, brick pavements, wood pavements, broken stone pavements, street-car tracks in paved streets, etc.

xvi. + 651 pages. 6 x 9. 97 figures. Cloth, $4.00 net.

Dust Preventives and Road Binders

By PRÉVOST HUBBARD.

Road engineers will obtain from this book a working knowledge of the characteristic properties of dust preventives; it develops fundamental principles relative to their selection and use. It gives the methods of testing road materials, selection of dust preventives and road binders and classification of dust preventives and road binders.

vii. + 416 pages. 6 x 9. 51 figures. Cloth, $3.00 net.

ON APPROVAL OFFER

If cash accompanies your order, we will forward copies of any of these books on ten days' approval. If they should prove unsuited to your needs we will refund your money, provided the books are returned within ten days after their receipt.

Port Arthur, Ont.—The department of public works, Ottawa, has awarded contract for breakwater extension to Chambers, McQuigge and McCaffrey Co., Ltd., Toronto. Contract price, $684,000.

Port Elgin, Ont.—Sealed tenders will be received by the department of public works, Ottawa, until 12 o'clock noon, August 5th, for repairs to wharf and partial reconstruction of breakwater. Plans and specifications may be obtained from the district engineer, Toronto, and from the post-office, Port Elgin, Ont. R. C. Desrochers, secretary.

Scotch Cove, N.S.—No contract for breakwater extension has been awarded by the department of public works. The work will be done by day labor.

Shippigan Gully, N.B.—Tenders will be received until noon, August 5th, by R. C. Desrochers, secretary, department of public works, Ottawa, for repairs to breakwater at Shippigan Gully, Gloucester County, N.B. Plans and forms of contract can be seen and specification and forms of tender obtained at the department of public works, Chatham, N.B.; St. John, N.B., and at the post-office, Shippigan Gully, N.B.

St. Michel de Bellechasse, Que.—J. B. Gallibois, St. Pierre, Que., has been awarded contract for repairs to wharf by the department of public works.

Toronto, Ont.—A system of life-saving stations will probably be established immediately by the city of Toronto. The Dominion government has agreed to give $20,000 towards capital expenditure and $3,000 per year maintenance. The board of control has recommended an annual expenditure of $30,000. The Harbor Commission will also expend $3,000 per year toward the same project.

Toronto, Ont.—The Toronto Harbor Commission will construct a new wharf at the foot of Hiawatha Ave., Centre Island, Toronto, and rent same to the Toronto Ferry Co. Ltd. Approximate cost, $6,000. E. L. Cousins, chief engineer.

Toronto, Ont.—The board of control will construct temporary breakwater protection for the eastern beaches this summer.

Toronto, Ont.—Tenders will be received by T. L. Church, chairman, board of control, until noon, July 28th, for the construction and delivery of 20-inch cast-iron pipes and valves for St. Clair Ave., from Keele St. westerly, and for laying of same. Specifications and tender forms for the foregoing may be obtained upon application at the office of the water main extension section, department of works, room 320, city hall, Toronto.

Vancouver, B.C.—Water out of Roberts Creeks, draining into the Gulf of Georgia, will be diverted for irrigation purposes by L. H. Roberts.

Winnipeg, Man.—The department of public works, Ottawa, has awarded contract for alterations and additions to service building at the Military Hospital to Carter-Halls-Aldinger Co., Ltd., Winnipeg, Man. Contract price, $29,000.

Yorkton, Sask.—The plumbing and heating contracts for the new court house has been awarded to Whiteford Bros., Regina. Contract price, $13,500.

Tenders Called For

TENDER FOR SEWERS

Tenders, sealed and marked, will be received by P. J. Anderson, Clerk, Newmarket, up to noon, August 7th, for the construction of storm and sanitary sewers in the town of Newmarket.

Plans and specifications may be seen at the office of the engineers, James, Loudon & Hertzberg, Limited, 36 Toronto Street, Toronto, or at the office of the Clerk, Newmarket.

The lowest or any tender not necessarily accepted.

W. EAVES, Mayor P. J. ANDERSON, Clerk.
JAMES, LOUDON & HERTZBERG, LTD., Engineers.
303

CITY OF SASKATOON

NEW 1,500 K.W. TURBO GENERATOR SET

TENDERS INVITED

Tenders are invited upon the following:—
First Contract—One Steam Turbine.
One Alternating Current Generator.
Switchgear Equipment.
Second Contract—One Surface Condenser and Condenser Auxiliaries.

Forms of tender, instruction to bidders and general conditions can be obtained upon application to the undersigned.

Sealed tenders, endorsed "Turbo Generator," must be delivered to the City Commissioner on or before 12 noon on Tuesday, the 23rd day of September, 1919.

The lowest or any tender not necessarily accepted.

C. J. YORATH,
City Commissioner.
July 18th, 1919. 304

Condensed Advs.

Advertisements under this heading at following rates per insertion, with fifty cents per insertion as minimum rate in any case; "Positions Wanted," one cent per word; all other condensed advertisements, three cents per word. Payable in advance; 50 per cent. extra if charged.

POSITION WANTED by Civil Engineer. Considerable experience in municipal and construction works; good draughtsman; references. Apply Box 374, *The Canadian Engineer*, Toronto.

CIVIL ENGINEER, with a number of years' experience in construction and municipal work, desires a position with an Industrial Concern where his experience and training could be of use. Apply Box 372, *The Canadian Engineer*, Toronto.

CIVIL ENGINEER, age 27, with first-class technical qualifications, able to design structures in steel and reinforced concrete, good draughtsman and estimater, seeks engagement with a firm of consulting engineers or a construction company, preferably one specializing in reinforced concrete. Box 392, *Canadian Engineer*, Toronto.

ENGINEERING EXECUTIVE.—Mechanical engineering graduate of Toronto University, fifteen years' general engineering and business experience, nearly four years' experience in aeronautical engineering, lately chief engineer of large aeroplane plant, now closed owing to termination of war, desires position with industrial concern where his experience and training could be of use. Good knowledge of engineering materials. Member of Society of Automotive Engineers. Would consider connection with established firm of mechanical engineers or manufacturers' agents handling engineering lines, where an interest could be acquired if desired. Address Box 388, *Canadian Engineer*, Toronto.

The Canadian Engineer

A Weekly Paper for Civil Engineers and Contractors

Construction of Water-Bound Macadam Roads

How To Prevent Their Destruction By Modern Automobile Traffic Proves a Serious Problem for the Highway Officials of Quebec Province—Translation of Paper Read in French Before the Canadian Good Roads Association

By A. PARADIS
Assistant Engineer, Department of Roads, Province of Quebec

SINCE the inception of the good roads movement in Canada, macadam has been the type of pavement most generally adopted. The paving methods of Macadam and Tresseillet had acquired great popularity in Europe, and, like a good many other progressive ideas, soon drew the attention of the American nations.

It did not take long for the provincial governments (at least for the Quebec government) to grasp the opportunity offered by this type of pavement for the betterment of rural roads in Canada. In this province the proposition was rapidly thought out, and was developed at a rate of approximately 400 miles per annum, since 1913. The Province of Quebec owns, at the present time, approximately 2,500 miles of macadamized and gravel roads. The pace does not seem to diminish, but a new problem, somewhat difficult and full of unknown factors, presents itself. It is that of up-keep of water-bound macadam.

The extraordinary development of commerce, industry and agriculture in the last twenty-five years have naturally revolutionized the transportation methods considered sufficient up to that time. It was considered sufficient up to that time to maintain the exchange of merchandise and of movement of traffic. At present, however, industry is becoming decentralized, spreading out around the cities and reaching even the small country villages. The distributor wishes to cover with his goods the largest possible area in the minimum length of time. Intensive and up-to-date farming necessitates the immediate distribution of farm products to the cities. The railways, excellent as they are for transportation in large quantities, do not provide a sufficiently detailed distribution.

The whole of commercial life has seized the advantage offered by the development of the automobile and auto truck industry to enlarge the radius of its businesses, and to add to pleasure trips. This entails boundless competition. As soon as good roads are developed and multiplied, truck traffic increases in density, and speed craze appears. Passenger automobiles ply between Montreal and Quebec, and are now reducing the time necessary for the same trip by railway.

Cannot Carry Heavy Traffic

The strength of water-bound macadam is not sufficient to bear the heavy loads, which seem to increase endlessly. The blows of auto tires running at 35 or 40 miles an hour, tear out the surface stones and leave voids which promptly grow larger. Against these multiplied factors of disintegration, it seems as though macadam will have to be given up on most highways. A good many efforts have been made to solve the practical problem of the up-keep. None of the proposed solutions have been entirely satisfactory. This is so much the case that, in engineering circles, one no longer hears anything but concrete, bituminous macadam, bithulithic and Warren pavements, etc. All these pavements have deserved the somewhat pompous title of "Superior Pavements." They are indicated from every point of view on main highways, and in the vicinity of cities, but on account of their very high first cost they are not suitable for roads of purely local importance. All the roads which serve as tributories of the main highways, towards farms and villages, come in this latter class, and as the provincial government, which controls paving programs, is much interested in the welfare of the farmers, it is practically certain that at least 50% of the mileage that will be constructed will be water-bound macadam.

Estimate of Annual Cost

Even if one leaves out all the factors of preference and if one considers good roads as a purely economical problem, the kind of construction that will be adopted under certain given conditions will depend on the annual expense for up-keep for the different kinds of pavement proposed. That is to say, the yearly interest on the capital to be expended, the yearly cost of up-keep and sinking fund. Taking for example a concrete pavement costing $20,000 a mile, with probable up-keep expenditure of $75 per mile per year, and a sinking fund period of, say, thirty years, interest being figured at 5%, and comparing this with a water-bound macadam whose first cost would be $7,000 a mile, and up-keep cost of $300 per mile per year, with a sinking fund period of ten years, interest rates being the same in both cases, a little calculation shows us that the yearly cost of delivery of the concrete road will be $1,376 a mile and that of water-bound macadam $1,206 a mile, showing a difference of $170 per mile per year in favor of water-bound macadam.

Under such conditions as outlined above, macadam should in every case receive favorable consideration as against concrete. This logic cannot be side-tracked, but, a difficult problem is to arrive at the proper factors which vary widely both as to yearly up-keep and as to sinking fund period. Figures which statistics and experience seem to favor to-day as a rational basis for estimates will in a few years be replaced by others widely different because at that time the traffic conditions will have changed and construction methods will be much improved. However, the proposition remains the same, and although certain factors of the problem may change, the theory will remain the same. We can foresee the capitalization as based on the present data will favor water-bound macadam for roads of local importance, and that a good many milions will yet be expended to extend and complete the system of macadam roads in the Province of Quebec.

We know, also, that considerable sums will have to be put aside for the up-keep of these macadam roads. Under these circumstances we may be sure that the provincial and municipal authorities will give a good deal of attention to this type of construction, and the engineers of the Department of Roads of Quebec are working towards a more perfect solution of the problem of construction and up-keep of water-bound macadam. Our climatic conditions and the nature of the available materials differ so widely from those of Europe that although European countries are ahead of

us in road building, we cannot follow here the methods currently used in France and England. Even among American and Canadian engineers we find quite a diversity of opinion on this subject. This is quite natural, as we cannot suppose that speaking from personal experience the New York engineer will have the same ideas as the man who has been building roads around Lake St. John. This is due, of course, to sub-soil conditions. The autumn rains and the intense colds following thereafter, place the Province of Quebec in an unique position which cannot even be compared with that of the states of Vermont and New York close by.

Quebec Problems Different

Quebec roads must be studied, free from all theories obtaining in other countries. We know that the provincial department of roads has always given its full support to the experiments of their engineers. The special conditions found in our province are: Firstly, the heavy winter frosts which penetrate several feet into the earth and cause heaving. Secondly, the nature of the materials to be found locally and which must be used to the best advantage. We cannot here go extensively into these two subjects. Let us remark, however, that water-bound macadam, having relatively little elasticity and small resistance to shearing stresses, suffers considerably from the disturbances caused by frosts. The only way to obviate, to a certain extent, this disintegration is to keep away from the roads the water resulting from the autumn rains.

Drainage, therefore, plays a very important part in this work and neglect of ditches and curbs will entail much more serious consequences than is generally known. However, in a good many cases the drainage is not sufficient to prevent infiltration, and in these cases means must be taken to catch the water before it penetrates under the road.

Water penetrates through the shoulders from ditches when their grade is poor, and even sometimes from the surrounding land, especially in cuts.

The construction of a longitudinal drain below the foundation will intercept the water and maintain the road in a sufficiently dry state, and so nullify the action of frost. The cost of these drains put down after the method adopted by the Department of Roads of Quebec is approximately 25c. per lineal foot, and increases the cost of construction of macadam roads approximately 10 or 15% for a drain on one side only. This relatively high cost is probably the reason that drainage has not been more extensively adopted in municipal road work. It is, however, recognized that under the very unfavorable circumstances, drainage must be used to avoid the necessity of reconstructing the macadam surface every spring.

Field Stone and Limestone

Field stone is most usually employed in the construction of water-bound macadam in Quebec. Quarries are not usually sufficiently scattered, and the cost of transportation is, as a result, too high to permit the use of quarry stone on road construction in all parts of the province. Besides, nearly all our quarries produce limestone, for example, the quarries of Montreal, Quebec, Deschambault and Joliette. These limestones are homogeneous and free from defects and mesh very well, but experience seems to show that they are not sufficiently hard for the necessary resistance to wear for heavy traffic. However, for roads of purely local importance, which are exactly the ones that should be built with water-bound macadam, these limestones should be used wherever their cost is comparable to that of field stone.

Despite the advantage of limestone, it can be foreseen that field stone will be mostly used in macadam roads. It can be found anywhere, and the use of it for road work enables the farmers to get rid of the rock heaps often to be found in their fields, which interfere with ploughing and harvesting. Field stone, as a result, is a mixture of different crystalized blocks, with granite and gneiss predominating. It is usually hard but somewhat brittle, and almost entirely lacking in the mesh qualities which characterize limestone and schist.

It would be difficult to make a careful choice of the various kinds of field stones scattered in small heaps in various farms, and in order to lower the cost of transportation, the best procedure is to use stone close to the road. Stone which is evidently of an inferior quality can be discarded before crushing. The discard will usually be small and comprise only stone too soft to be used for the wearing surface.

It is to be hoped that the installation in the various municipalities of permanent up-keep gangs and foremen will enable this selection of stone to be made in the winter.

Macadam, as invented and practiced by the originators of this system of road building, was meant to have a smooth, hard surface, and the union of the stone should be sufficiently effective to render the wearing surface almost as hard as concrete. European nations have come close to this idea, and the French people especially find it quite natural that a water-bound macadam road should give them 15 or 20 years of hard service without the necessity of resurfacing.

European Methods Not Applicable

Let it be well understood, however, that the European procedure cannot in every case be applied to Canadian roads. In France the abundance and low cost of labor enable the crushing to be done by hand, at least for the surface course. They attain in this manner carefully selected stone, practically cubical in shape, and varying in size only from 1½ ins. to 2½ ins. This is quite different from the product of crushers which often give flattened stone with sharp angles easily broken up under the roller, which enlarges the proportion of small pieces. It must not be said, however, that these defects of jaw crushers necessitate a revolution in our system of road building. This country is young, labor is scarce and consequently to be spared whenever possible. We must therefore substitute machines. Even with the high salaries latterly paid, the cost of crushing has hardly exceeded 50c. per cubic yard.

We must calculate therefore on the principle that we must make the best of the situation as we find it, as the aim is to better the crushing and so to grade and crush stone as to introduce here, as much as they may be applicable under our conditions, the processes which experience has proven to be most efficient in other countries.

The three principal points to be carefully watched in crushing are the speed of the machines, the renewing of worn-out jaws, and a proper arrangement of screens for grading. It is easily seen that speeding up the crushers means that stone crushed to the proper size in the upper end of the jaw will be crushed once again before getting out of the bottom, and this will result in too many small fragments. It is therefore necessary to choose a crushing speed which will prevent this, and will at the same time be sufficiently fast to give an economical output. The high price of jaw blades, which has become exhorbitant in the last year, has resulted in the use of worn jaws (by some contractors and foremen) until the jaws are perfectly smooth. Flat stones can therefore pass through the crusher and make their way to the screen in sizes which cannot be used.

It is therefore essential that jaw blades be carefully inspected, and a good foreman will not await orders of the engineers to replace these when they are worn out.

Small Stones Undesirable

Careful attention to the first two points will practically eliminate the third. It can easily be seen that by diminishing the proportion of small pieces, narrower limits as to size can be set down, and we would thus use for the wearing surface nothing but stones from 1½ to 2½ ins. This can only be done provided that there is not too much reject and that the small stones from ¾ to 1½ ins. will prevail only in sufficient quantity to be used up as filling material in the foundation courses.

The undesirability of small stones is very apparent when one knows how difficult it is to maintain a good bond on roads macadamized with field stone. It is easily seen that the force exerted on macadam surfaces by passing vehicles is the resultant of two forces, one (vertical) being the weight of the load, the second (horizontal) being the tractive effort of the vehicle. These two forces are very variable. In the case of an automobile travelling at high

speed, the horizontal force becomes very high and tears out the stone and destroys the bond of the surface. In the case of a steam roller, the vertical force is much more apparent and therefore the roller is employed to rebuild the surface which the horizontal force destroys.

It is out of the question to restrict the speed of automobile to a point where they will not be harmful. The only solution is to offer to the pneumatic tire the solid surface with not only the necessary hardness but also the necessary weight and tensile strength.

The larger the stones composing the surface, the better the contact with adjoining stones and the more the macadam will be compact and massive. The means mentioned above for reducing the proportion of small stones, will help considerably towards the desired result. The limit as to the size of stone which will permit a sufficiently smooth surface for present vehicles is approximately 2½ ins.

Use of Limestone Dust

Another method of lengthening the life of macadam and at the same time diminishing the up-keep cost of field stone macadam, is to use limestone dust as a binder.

There is in the Parish of St. Jean-Chrysostome, in Chateauguay County, a road built in 1913 with field stone and a limestone dust binder. This road has carried continually very heavy traffic, and in addition carries the transportation of stone for the construction of surrounding roads. In 1918, after five years of continuous service, there were no apparent ruts and no loose stones, although the crown of the road has almost entirely disappeared through wear.

The value of a limestone binder in connection with field stone is pretty generally recognized, but fear is often expressed that the advantage to be obtained will not be proportional to the extra expense due to the purchase and transportation, often for long distances by rail, of this limestone dust, which cannot be obtained outside of quarries. If we take it that the quantity necessary for good results is equivalent to a layer ¾ in. thick, the necessary quantity for one mile of 12 ft. road would be 146.6 cubic yards, and as we may reasonably suppose an average cost of $3 a yard, the cost of the road would be enhanced by $440 a mile, which is an increase of 6.3% in the cost of a road costing $7,000 per mile.

If we now take it that by the use of this process we succeed in lengthening by 20% the life of the macadam, it will be economical to use this dust. We see in this way that the reduction in up-keep cost would more than cover the interest on the additional capital used up in the construction.

Limestone quarries are unable to furnish in large quantities this binder, which consists of particles varying from ½-in. to the finest dust. In some parts of the province this dust may be obtained in its natural state. The binder which was used on the above-mentioned road in St. Jean-Chrysostome, was found right in the parish and so close to the road itself as to be quite economical.

Common Errors in Construction

It is often found in practice that a number of mistakes and omissions occur in the detail of construction as written in various specifications generally used at the present time. We must recognize that specifications, however elaborate, offer always sufficient leeway that the contractor may use his personal views and methods. I think it advisable to enumerate here certain methods frequently found which seem really bad, and the suppression of which would bring us nearer to the methods in use in European countries, which possess at the present time the finest roads in the world.

Certain foremen and contractors have the habit of considering in every case crusher dust as a binder. This error is due to a false idea of what takes place in the interior of the macadam during rolling. Under the pressure of the roller, the stones mesh themselves as to produce strong friction between the surfaces in contact. This friction produces a very fine dust which is the best possible binder when the stone possesses binding qualities. This binder will be very efficient if sprinkling takes place at the same time.

Stone which will not bind without previously filling the voids will not bind any better with its own dust. In filling the voids with dust before rolling, one may obtain a macadam with an apparently compact and even surface but which will disintegrate in a few dry days. However small the proportion of binder in the stone, the macadam must be watered and rolled, but never rolled dry until the macadam is very compact and the voids reduced to a minimum. This is the time to spread crusher dust to fill what voids may remain, and thus render the surface still more compact and sufficiently impervious to water.

Must Apply Small Quantities

We must, however, make one exception. This is when limestone dust is used as a binder. Limestone must be applied in successive very small amounts as soon as the rolling begins in order to enable the limestone dust to penetrate gradually between the stones. This operation must be watched in order to prevent the application of an excessive dust at the beginning of the rolling.

We witnessed some years ago a typical case showing the undesirability of an excessive dust in the macadam. A contractor in perfectly good faith had gotten the habit of placing all the crusher dust, including the small fragments up to ¾-in., in the last layer of stone. In order better to obtain this result, the dust was spread before any rolling over the stone, which was entirely covered. Be it noted that the stone was of good quality and contained sufficient binder to give results. Nevertheless, it was only after prolonged rolling, renewed at intervals after several weeks, that he was able to obtain a satisfactory bond. One could, however, see at the same place a piece of macadam built the previous year in the same fashion, which showed a rough and uneven structure which could not be charged to wear, age or heavy traffic.

One might claim to upset this principle by showing a new macadam built after this style and sufficiently bonded. This would merely show that the stone employed was very easily bonded, and in any case the argument would only last for the time necessary for traffic and wind to destroy the layer of dust with which the surface of the macadam is camouflaged.

Cannot Interrupt Sprinkling

Another very common error in construction consists of carrying sprinkling water a considerable distance in the sprinkler itself. This means that sprinkling is interrupted for considerable intervals, during which the rolling continues under unfavorable conditions. We must not forget that the water is one of the principal materials in the construction of macadam, and although it may be true that certain limestones bind fairly well when dry, it is also true that this bond will be much more effective if treated with water at the proper time and in sufficient quantities.

It has often been noticed that in clay regions the surface of a macadam road is deteriorated for 200 or 300 ft. at each end by the clay which the wheels of vehicles spread on it. This defect which everybody sees and which is considered almost inevitable, could be much diminished by proper precautions and principally by ending the macadam with special care. Last year there was to be seen in the Parish of St. Malachie, in Dorchester County, a macadam two years old which had kept its shape and surface without any deterioration up to the point where it joined a clay road. The contractor who built this road was an artist in road construction. Would that he might have many disciples!

The up-keep of macadam roads in Quebec began two years ago, when the first signs of deterioration and of wear appeared in the roads constructed in 1912 and 1913. Two years are very short to study a problem which can only be solved through experience. It is not easy to obtain at the present time a general rule which will apply to the special conditions in our province. There are, however, certain causes of deterioration of macadam which leave no doubt as to the best measures to retard and nullify their effects.

Frost, for example, disintegrates more or less all macadam roads. This is not surprising, since the effect of frost can be seen even on solid roads. We can, therefore, adopt the practice of rolling anew every road each spring as soon as the frost has disappeared. We must not forget that this rolling must be preceded by the ordinary sprinkling. Sometimes the sprinkling may be avoided if the weather is rainy at the beginning of the summer, but it is not advisable to delay this work too long awaiting rain. The cost of rolling and sprinkling might reach approximately $100 a mile per year.

The heaving of the soil produces blisters which are a cause of rapid deterioration. These can be eliminated by drainage. If the system of drainage employed during the construction of the road has been insufficient to keep the road from infiltration, some means will have to be devised to eliminate water from the affected spots. Tile drains are usually advisable in these cases.

The cleaning out of the ditches and curbs is imperative each year and should be done in the first days of spring, before vegetation gets a chance to take root. In flat country, such as the land to the south of Montreal, at Laprairie, Chateauguay and Huntingdon, it often happens that

MUNICIPAL ENGINEERS AND TOWN PLANNING

By Thomas Adams
Town Planning Adviser to the Housing Committee of the Dominion Cabinet, Ottawa

THERE was a time in Britain when the engineer looked somewhat askance at town planning and regarded it as sort of a fanciful idea promoted by impracticable idealists. The period of this attitude ended about 1911 when the town planning act became really operative and engineers began to take up the subject as a part of their daily practice. Ever since then the annual meeting of the Institution of Municipal and County Engineers has included one or more papers on town planning in its program and on two or three occasions has dealt almost exclusively with town planning as the subject for discussion at their annual meeting. Such eminent municipal engineers as John Brodie, of Liverpool, and H. E. Stilgoe, of Birmingham, are prominent members of the council of the Town Planning Institute, and have promoted, in their own cities, town planning schemes for most of the undeveloped building land.

The last annual meeting of the institution was held June 26th to 28th, in Birmingham, under the presidency of Mr. Stilgoe. This is the last occasion when Mr. Stilgoe may preside as a city engineer, since he has been appointed as chief engineer of the Metropolitan Water Board of the County of London.

At the Birmingham meeting, a town planning paper was presented by James Thomson, the city engineer of Dundee. Its subject was "Housing in Relation to Town Development." Mr. Thomson indicated the connection between housing and town planning from the standpoint of the engineer, and how the fact that they were inseparable parts of well considered schemes of expansion made them pre-eminently engineering questions. He pointed out how the absence of any comprehensive plan has produced disastrous effects to amenity and housing conditions. Plans of development, he suggested, should sufficiently meet not only the present-day requirements but also the needs of every locality for a period of not less than 50 years.

Mr. Thomson indicated the following main proposals which local authorities should consider in relation to housing and land development:—

(1) Absolute change from the present method of town growth as one mass without intervening spaces.

(2) Acquisition at every opportunity of undeveloped land at as near its agricultural value as possible.

(3) Design of the frame work or skeleton of all existing and proposed main roads, excluding subsidiary roads, within a well-considered probable extended boundary.

(4) Limitation in the size of all new combined industrial and housing areas to a maximum to be fixed by the local authority.

(5) Separation of all new combined industrial and housing areas from each other, and from existing areas by open spaces and wooded belts.

(6) Complete revisal of former methods of lay-out of land for working-class dwellings.

(7) Drastic change in the design, type, size, equipment and environment of houses for the working classes.

(8) Reduction of housing density.

(9) Sufficiency in all housing schemes for gardens and allotments and facilities for culture.

(10) Certainty that in all new works areas, housing shall be carried out on town planning lines.

(11) Allocation to each new housing and industrial area of sites for buildings necessary for culture and recreation facilities.

(12) Facilities in every new housing unit for out-door recreation for adults and children.

(13) Increase in the number of small parks corresponding with the increase in number of housing areas.

(14) Transit facilities to outlying districts and to all new industrial and housing areas.

(15) Abolition, step by step, of all slum areas.

(16) Improvement by degrees of central area and of all congested districts.

(17) Gradual widening of central main streets and the early widening of portions of arterial roads in the outskirts.

(18) Preparation of town planning schemes for all areas proposed or brought within boundaries in conjunction with town planning of areas within the existing town.

(19) Extension of railways and provision of railway sidings into land to be used for industrial purposes.

(20) Appropriation of sites for landing grounds in anticipation of the introduction of aerial transport in conjunction with the fixing of housing and industrial areas.

Mr. Thomson pointed out that as expansion of cities took place, the necessity of a combined scheme of housing and development became more and more necessary.

Cities would continue to grow as formerly and would consist of an aggregation of houses, industrial buildings and streets massed and expanding without method. He claimed that there was a large responsibility resting upon municipal engineers to prevent the laying out of roads "insufficiently wide and illogically placed, public buildings erected without regard to suitability of site, traffic and transport convenience neglected, and, generally, a haphazard accumulation of all that goes to make a town unattractive and depressing."

We have still some progress to make in Canada in getting the municipal engineers to take such an active part in promoting town planning as they seem to be doing in Great Britain. Now that we are gradually getting the needed legislation, it is certain that engineers will give more attention to the subject.

One of the directions in which we need to make progress in Canada is in providing more education in our universities to engineers and architects on town development, and it is hoped and expected that this defect will be made good in the near future.

In connection with housing there is a tendency in Canada to promote schemes of building houses on vacant lots in parts of the cities that are already in course of development. This does not give the engineer who has ideas, any opportunity of assisting in securing an efficient and economical system of building houses and laying out local improvements—matters which go together.

One of our tendencies is to have stereotyped rules fixing width of streets and other things in connection with land development, leaving no initiative to the engineer. The time has surely come when the members of the engineering profession who specialize in municipal work should get together and co-operate, with a view to giving more influential direction to some of the problems of town development. We have just as great problems as they have in Britain and, being a new country, we have better opportunity to solve them.

STUDIES IN THE BACTERIOLOGY OF WATER*

By Denis B. Wood

IT is well known that bacteriological examinations of water supplies are directed to the detection and enumeration of what are known as "indicator organisms"—that is to say, organisms which are always to be found in large numbers in the excreta of man and animals. The presence of such organisms in water indicates potential danger to the health of consumers, for individuals suffering, or having suffered, even at some remote time, from typhoid fever and kindred diseases may void the specific organisms in large numbers in their excreta.

Contamination of water with excretal matter derived from animals is of less potential danger, for the lower animals are not to anything like the same extent subject to these diseases. They are known, however, to be subject to infection with the Gäertner group and paratyphoid bacilli, and with animal parasites, though such infections are rare, and contamination with animal excretal matter must be regarded as undesirable. Moreover, as we have as yet no means of distinguishing between contamination with human and animal excretal matter, so similar are their bacterial flora, we are obliged to take a safe course and regard all waters showing definite evidence of excretal contamination as more or less unsatisfactory.

There are three groups of "indicator organisms": (1) The B. Coli group, (2) the Streptococcus group, and (3) the Enteritidis Sporogenes group. The average numbers in which they are present in one gramme of human fæces are:—

B. coli.	Streptococci.	Spores of B. Enteritidis Sporogenes.
100-1,000 million.	100-1,000 million.	1-10 million.

It is evident, therefore, that tests based on the enumeration of B. coli and Streptococci will be the most sensitive. In this paper only these two groups will be considered.

The B. Coli Group

Members of the B. coli group have one characteristic in common—viz., the fermentation of lactose with production of acid and gas. The study of this group reveals the fact that it can be divided and subdivided into a number of types.

From MacConkey's result it appears that 87% of the lactose-fermenting organisms present in human fæces all produce indole, acid and clot in milk, do not liquefy gelatine nor give the Voges and Proskauer reaction. In other words, they possess, practically speaking, the cultural characters of Houston's "typical B. Coli." Houston found that about 85% of the lactose fermenters present in human fæces, and 65 to 85% of those present in sewage, possessed these characteristics.† The results of his investigations on the viability of members of the B. coli group in soil and water show that the atypical varieties persist for longer periods than the typical, and are therefore less characteristic of recent contamination. Houston's definition of typical B. coli is admirably suited to routine bacteriological examination, and has been very generally adopted as a basis for bacteriological reports.

The Streptococcus Group

It sometimes happens that in a water examination only lactose fermenters having the characteristics of Houston's "typical B. coli" are to be found. It is then a great advantage to have recourse to another test, and the most satisfactory corroborative test is based on the enumeration of streptococci. Savage and Read have shown that the majority of waters showing evidence of contamination on the B. coli basis contain streptococci.

In calculating percentages nothing is to be gained by working out the percentage of water-samples which contain streptococci or B. coli respectively in the different amounts. The percentage results are worked out in two ways. In one way each group of B. coli prevalence is taken separately and the percentage prevalence of each group of waters on a streptococcus basis is calculated. In the other way each group of streptococci prevalence is taken separately, and the percentage prevalence of the waters on a B. coli basis is recorded.

An example will make this clear. Take, for instance, 118 samples from deep-water supplies containing B. coli in 10 or 30 cm.; 58 or 49.2% contained no streptococci. Or take the 198 samples from deep-water supplies containing no streptococci; 64 or 32.3% contained B. coli. The mean of these two numbers (49.2 and 32.3) is 40%, and gives a fair average of the number of samples in which B. coli may be present in only moderate numbers and streptococci absent. In other words, the chances are rather more than even that streptococci will be found, and if not found in one sample they probably will be in the next, or at any rate in subsequent examinations. This correlation between B. coli and streptococci is a point the author particularly wishes to emphasise. Apparently the value of this test as carried out by Savage has not been fully appreciated.

The streptococcus group can also be differentiated into a variety of types by fermentation reactions; those producing acid in lactose are particularly typical of excretal contamination. Differentiation of this group, however, is seldom practised.

Index of Recent Contamination

The streptococcus enumeration is particularly valuable as an index of recent contamination. This was shown by the results of an investigation carried out by the present author in conjunction with Dr. W. G. Savage on the relative viability of B. coli and streptococci in water under conditions closely resembling those of a well. In this investigation an earthenware pipe cemented at the bottom and holding about 40 litres of water was used as the model well. The water was contaminated with excretal matter emulsified with water, or with sewage, and examinations were made at regular intervals to ascertain how rapidly the organisms diminished in numbers and finally disappeared.

These experiments with excreta or sewage added to a large bulk of water yield minor differences in the individual experiments, but in general they show a rapid diminution and elimination of the streptococci and a continuous, yet not quite so rapid, diminution in the number of B. coli.. With the latter it was more common to find persistence in small numbers for a period extending to many weeks. The elimination of the streptococci was particularly uniform and rapid. At the end of three weeks in only two experiments were they present in more than insignificant numbers.

The decline curves of both organisms agree very closely, as could be seen most readily when the figures were plotted out as graphs.

Comparison with Typhoid Bacillus

Comparison with the viability of the typhoid bacillus is of special interest. Sir A. C. Houston's investigations in the viability of uncultivated typhoid bacilli in river water showed that they died out within three weeks, even when as many as 38,000 were present per c.c. of the infected water.

Several lactose-fermenting organisms isolated from various sources gave the Voges and Proskauer reaction, very few of which—only 6.3%—were represented in human fæces. These types have recently attracted the attention of American bacteriologists, and have been shown by them to be rare in the excreta of man and animals, more common in sewage and surface water, and the predominant types in soil and grains. They can be distinguished in the laboratory by two tests—(1) the methyl-red test, and (2) the Voges-Proskauer reaction, alluded to above. These two tests are very closely correlated, and by them the lactose-fermenting organisms can be divided into two main types, which are known as—

*From a paper read at the annual summer meeting of the Institution of Water Engineers, England.

†Since the large majority of organisms fermenting lactose and producing indole fulfil the other tests also, according to Houston's later definition, the other tests are dispensed with in routine examinations.

(1) The methyl-red positive type ("M.R.+"), or the Voges-Proskauer negative type ("V.P.—"), and

(2) The methyl-red negative type ("M.R.—"), or the Voges-Proskauer positive type ("V.P.+").

The first is characteristic of excretal contamination, and is sometimes called the "Coli type," while the second is not characteristic, at any rate, of recent excretal contamination, and is sometimes called the "Aërogenes type," after its type organism, B. lactis aërogenes.

These tests commend themselves to the bacteriologist as suitable for routine work in the same way as the tests of Houston, by their simplicity, and are particularly to be welcomed by those in whose experience particular water supplies have yielded only atypical varieties of lactose fermenters according to Houston's definition.

Results show how small a proportion of the lactose-fermenters of excreta belong to the "M.R.—" type, and how large a proportion are present in soil and grains. Occasionally a specimen of fæces contains a fairly large proportion, the high figure of 26% obtained by Rogers, Clark and Lubs was due to a single abnormal specimen, and to the employment of a method specially selected to favor the growth of this type, and does not represent the average numbers in which they were actually present.

Methyl-Red Negative Organisms Survive

Records of various observers strongly suggest that organisms of the "M.R.—" type are the more resistant, the more capable of surviving outside the animal body, and of finding a favorable environment in soil.

Winslow and Cohen carried out experiments on the relative viability of these two main types in water, and their results show that there is distinct evidence that the viability of the "M.R.—" type is greater than that of the "M.R.+" type.

Experiments show a decrease in the "M.R.+" type from 50 to 5%, and from 56 to 0% respectively (in sixty days). On the average, however, the reduction in the percentage was from 54 to 29.

As the methods employed by American bacteriologists differ in some respects from those usually employed in this country, it was thought advisable to investigate how frequently organisms of the "M.R.—" type were likely to be encountered in the routine examination of waters by English methods, and, by noting the association or absence of association with streptococci, to ascertain whether the presence of lactose-fermenting organisms of this type affords evidence of recent excretal contamination or not.

Observations were therefore made by the author of a large number of samples of water from various sources. Out of 200 samples in which lactose fermenters were present, organisms of the "M.R.—" type were encountered in 66, or 33%.

Lactose fermenters of the "M.R.+" type and streptococci were absent from practically every sample, strongly suggesting that in general no recent excretal contamination had occurred, for if it had streptococci would have been found in about 50% of these samples. [These samples were of water of good repute.]

Other samples from shallow wells, etc., were as follows:—

Samples from Shallow Wells

(1) Those containing no streptococci and no lactose fermenters of the "M.R.+" type, suggesting no recent contamination.

(2) Those containing streptococci and probably lactose fermenters of the "M.R.+" type also, though, since contamination was sufficiently proven, further search for this type was not made.

(3) Those containing streptococci and lactose fermenters of the "M.R.+" type, further search having been made for this type for the purpose of this investigation.

It may be asked, How is it that the "M.R.—" type are found in samples of groups 2 and 3 in which recent excretal contamination is proved? The explanation obviously is that a certain amount of self-purification has already taken place, but the contamination is sufficiently recent for organisms of the "M.R.+" type and streptococci to be present also in larger quantities of the sample.

Of special interest was the occurrence of lactose fermenters of the "M.R.—" type in the deep wells in limestone. This supply consists of seven or eight wells, several miles apart, varying in depth from 250-450 ft. These wells yield a very pure supply, lactose-fermenting organisms being absent from 100 c.c. in 85% of all samples examined. In the spring of 1918 lactose fermenters were found in a much larger proportion, and all (with one exception) were found to belong to the "M.R.—" type. Streptococci were invariably absent. The inference is that the most resistant types only of the lactose fermenters reached the underground water, though why they were present in abnormal numbers at this particular time could not be discovered. The only exceptionally heavy rainfall occurred five months previously.

Viability of Capsulated Organisms

The large majority of lactose fermenters of the "M.R.—" type (about 85%) show capsule formation. Experiments by the present author show that some capsulated organisms display remarkable viability in boiled (or steamed) hard water. In one experiment the organism added to such water, containing no measurable trace of saline or organic ammonia, was isolated after a period of three and a-half years. It should be noted that it is only in boiled (or steamed) hard water that such remarkable viability is observed, though in unboiled water some of the capsulated types live longer than the non-capsulated (in one experiment fourteen weeks as compared with seven weeks). The phenomenon seems to be dependent upon the slow deposition of supersaturated carbonate of calcium or hydrate of magnesium, which takes place in the boiled water after filtration. Whether the necessary conditions for prolonged viability occur in limestone silt is a matter worthy of investigation.

Other experiments confirming this remarkable behaviour, one of which was carried out independently by Dr. W. G. Savage, are recorded in the *Journal of Hygiene* Vol. XVI., No. 3, January, 1918. In periods varying from five to eleven weeks, multiplication from fifty to one hundred fold was recorded.

Both strain T. and strain N.D. gave the Voges-Proskauer reaction, and belong to the "M.R.—" type. Strain N.D. produced indole and acid and clot in milk, and was therefore indistinguishable from Houston's "typical B. coli," except by the methyl-red and Voges-Proskauer tests.

Summary

(1) Although attempts to distinguish between human and animal excretal matter by the characters of lactose-fermenting bacilli present have so far been unsuccessful, some measure of success has attended attempts to distinguish between recent and less recent contamination by the identification of the less resistent and more resistant types.

(2) Clemesha based his differentiation on MacConkey's classification; Houston on the more simple indole test. Savage retains the milk-clot test, and notes marked weakness of lactose fermentation, having shown that these attributes tend to diminish with soil environment. American investigators have recently based their differentiation on the methyl-red and Voges-Proskauer tests.

(3) The more resistant the types, obviously, the less evidence there is of recent contamination in waters in which they are found.

(4) Most valuable information as to recency of contamination is afforded by the enumeration of streptococci by the simple method of Savage.

(5) Association or absence of association of lactose fermenters with streptococci can therefore be used as a control in judging the merits or demerits of any of the above methods of differentiation.

(6) Relative absence of association of the lactose fermenters of the "M.R.—" type with streptococci strongly supports the view that they are the more resistant types.

(7) Experiments show that, under certain conditions, the viability of capsulated organisms of the "M.R.—" type may be very considerable. Whether similar conditions occur in nature is a matter requiring further investigation.

METERING AND WATER CONSUMPTION*

By H. P. T. Matte
Chief Sanitary Engineer, Illinois State Department of Public Health

In considering the effect of the installation of water meters upon the consumption of water, and in comparing the usage in various cities, three elements, which may have an important bearing upon the results, are seldom taken into account. These are:—

1. Pressure upon the water system.
2. Extent of house connections with sanitary sewers, especially the use of bathtubs and water-closets.
3. Effective size of mains and services.

Pressure of Water System

When per capita rates of consumption are published or mentioned, how often is the average pressure at which the water is supplied included? It is a mistake to omit that item, as it is an important one. A city with a higher pressure than another will find that its leakage rate, both through fixtures and underground piping, will be greater than that of another one which maintains a lower average pressure.

In Oak Park the per capita rate of consumption is easily varied between one and two gallons per pound change in pressure within the entire range of rates of consumption. That is to say, 10 pounds' variation either way will make a difference of 10 to 20 gallons per capita daily. Thus the Oak Park rate of 65 gallons per capita at 45 pounds' pressure can be reduced to 45 gallons at 25 pounds. In Niagara Falls, where the per capita rate of consumption was 300 gallons per diem, exclusive of the industrial usage, the writer determined this rate to be from 3 to 5 gallons per capita per pound change in pressure, or 30 to 50 gallons per capita for each 10 pounds. The Niagara Falls consumption was about 6¼ times that of Oak Park, and the average pressure was about 60 pounds, which accounts for the different limits; but the principle is the same and its importance is clearly seen. The pumping units were designed for a maximum rate of consumption owing to the heavy drafts, and, as there were no small units provided, the effect of reducing the fixture leakage by the installation of meters and the house-to-house inspection was to boost the pressure at night some 30 pounds greater, or to 90 pounds; and the effect of reducing the leakage was not evident owing to the greater discharge of water through the remaining defective fixtures.

The following table shows one of the uses of water affected by pressure:—

A ¾-inch hose 50 feet long with nozzle at 60 lbs. consumes 5,000 gallons per day if in form of jet; at 30 lbs consumes 3,600 gallons per day if in form of jet; at 55 lbs. consumes 10,000 gallons per day if in form of spray; at 30 lbs. consumes 7,200 gallons per day if in form of spray.

These figures have been obtained from tables prepared by Manager Sullivan, of the Nashua, N.H., Water Co.

Connections with Sanitary Sewers

Another element which is noteworthy in its effect on water consumption is the use of water-closets and bath tubs, although the number of consumers on the line of pipes are often considered in computing per capita consumption. It is seldom that the number of consumers which have the use of faucets only are separated from those which have all the sanitary conveniences.

In Oak Park, from numerous experiments, we determined that the average number of gallons per capita consumed by water-closets where no leaks or waste existed was 20; while under the same conditions the average family consumed 15 gallons per capita through bath tubs. An interesting fact connected with the use of bath tubs is that a person who takes cold baths every morning is very likely to consume 40 gallons per day in this item alone. A psychological effect of the lack of pressure, consequently an increase in length of time required to fill bath tubs, oftentimes reduces the quantity of water used for baths.

The records from the following cities show the effect of the installation of sewers upon the general water consumption:—

City.	Before Installation of Sewers.	After Installation of Sewers.
Marlboro, Mass. .	21 g.p.d. per capita	38 g.p.d. per capita
Newton, Mass. ..	31 g.p.d. per capita	63 g.p.d. per capita
Waltham, Mass. .	32 g.p.d. per capita	70 g.p.d. per capita

In Madison, Wisconsin, the per capita daily consumption in residences with sewer conections was 68, while in residences without sewer connections it was 14.

In Rochester, N.Y., services with water-closets consumed 22 g.p.d. per capita; services with water-closets and no baths, 18 g.p.d. per capita; services with water-closets or baths, 14 g.p.d. per capita.

The limited extent of services and sewer connections in foreign cities, thus cutting down the number of outlets for consumption and fixture leakage, is responsible for the low per capita consumption in those cities. From figures obtained three or four years ago, it was noted that the large European cities of over 2,000,000 population had about as many service connections as the average city of 300,000 in this country, while the number of services in foreign cities of about 350,000 population equalled that of our cities of 40,000 population.

Effective Size of Services and Mains

The data on this subject is limited, but difficulty is experienced through loss of pressure by friction from the reduced area of corroded lime-coated service pipes and water pipes filled with algae, crenothrix and tubercles, indicate the importance of the effective size of service pipes and mains on leakage and waste. Water bills on metered premises in which leakage and waste exist often double in size after the renewal of service pipes, both in the ground and in the interior of the house especially when iron pipe has been replaced.

The following table compiled from some experiments conducted by the New York Department of Water Supply, Gas and Electricity, throws more light upon the subject:—

Pressure in street mains required to give the tabulated discharge through a corporation cock and 30 ft. of lead service pipe.

Gals. per Min.	1-in. Service.	¾-in. Service.	⅝-in. Service.
5	.....	2 lbs. sq. in.	3 lbs. sq. in.
10	.....	5 lbs. sq. in.	10 lbs. sq. in.
15	3 lbs. sq. in.	11 lbs. sq. in.	23 lbs. sq. in.
20	5 lbs. sq. in.	18 lbs. sq. in.	38 lbs. sq. in.
25	8 lbs. sq. in.	28 lbs. sq. in.	54 lbs. sq. in.

This table also gives the difference between the pressure at the main and the house side of the service under pressure.

Use of Water Meters

Having considered the items which affect domestic water consumption as governed by local conditions irrespective of industrial and other usually recognized conditions, we may now discuss the meter question.

Can one imagine a gas company or an electric utility selling its commodity without measuring it? Doubtless though, it is easier to tolerate the waste of water because it is not seen or appreciated. Gas leakage is offensive and dangerous. Wasted electrcity is mainfested by motion, light or heat; hut water disappears unnoticed into the sewers. Yet the speaker knows that in an Eastern city where electric-light current was sold under the flat rate system, electric-light bulbs on numerous porches remained turned on all day long. Queries brought the answer that it did not matter as there was no meter. What can the effect be on the water consumer of this type when the water consumption is not metered? In fact, in this same city, which

*Excerpts from a paper read before the annual convention of the Western Society of Engineers.

was only 28% metered, the fixture leakage per capita, as determined by an extended survey, was 205 gallons daily.

Any student of water consumption and waste knows that underground leaks contribute little to the waste included in high per capita statistics. From his experience in Oak Park and elsewhere the writer affirms that the periodical inspection of fixtures in lieu of complete metering is entirely unsatisfactory. When avoidable leakage will occur through meters, what can be expected when there is no automatic check on the consumption?

In Oak Park it has been observed during the past four years that the annual number of high bills complained of, including those places at which the same conditions obtained two or three times a year, dropped from 33 to 10% of the total number of services, due to education of the consumer. Without meters there would have been few complaints and much increase in waste and leakage.

Meters vs. Inspection

It is most difficult to control fixture leakage by inspection on account of the recurring of the waste as soon as the inspection has been made. In order to do the work that the meter does, it would be necessary to make inspections every month, at least, and in the case of an ordinary residence, it takes about four times as long to make an efficient inspection as it does to read a meter. In apartment buildings an inspection is a thankless job because all the occupants are seldom at home at the same time. The work, therefore, is usually slighted.

It has been found also that efficient fixture inspection is more objectionable to tenants than meter reading because the inspector has to pry into the privacy of the home. The landlords who dislike to pay plumbers' bills for the repair of poor plumbing are the ones who object to meters. In New York it was noted that after six months' work the inspector was stopping leaks at about the same rate as the leakage previously stopped was reappearing.

Unmetered water in completely sewered cities with universal sanitary facilities is usually sold at less than cost per thousand gallons.

In Boston with the gradual introduction of meters up to 60%, the capita consumption dropped from 130 gallons to 90 gallons and in this city vigorous house-to-house inspection was previously practiced. The same may be said of most cities which are metered, although in a few, owing to lowered water rates, with too great a minimum allowance, industrial use, and the other factors which are mentioned above, the curve is more erratic.

Methods of Control

For the past five years the water department of Oak Park has made an intensive study of water consumption with a view of reducing to a minimum the waste, and consequently the quantity of water purchased from Chicago. The city is, and always has been 100% metered, and it has been found that without meters a further material reduction in needless waste would have been an impossibility. In 1913, according to the accepted standards, the Oak Park per capita consumption of 75 gallons was very low, indeed. The night rate of consumption for the total system, however, was 58% of the average daily consumption, while 20% seemed to be a fair ratio for a city composed principally of high-class residences with few industries.

As a result of the waste campaign the daily per capita consumption of Oak Park has decreased from 75 gallons in 1913 to 65 gallons in 1918. Yet who can say that Oak Park is not one of the most sanitary cities in the state of Illinois, if not in the whole country?

There are no privies in this city, every house being connected with the sewers. All the consumers have the benefit of water-closets, 95% have bath tubs; and the bathroom consumed about three-fifths of the water used for domestic purposes. Moreover, every building has a lawn, every street has a grassed parkway on each side of the roadway. From inspection of records of sanitary surveys in various cities with lower and even greater per capita consumption than Oak Park, it was found that the number of premises not connected with the sewers varied between 20% and 80% of the total. Every home in Oak Park is connected with the water supply and there are no active wells except two deep wells used by a gas company as a supplement to the city water, and consuming one gallon per capita. In other cities of which we have record, the wells number 5% to 81% of the total number of buildings.

From the foregoing it follows that Oak Park should use more water than the average city, regardless of relatively small industrial use, because in many cities with industrial plants the big users have access to river, lake or well supply and use the city water only for emergency use or for drinking water.

The Waste Problem

It will be noted that the night rate of pumpage will often be from 80 to 90% of the average daily consumption. This is indicative of much waste. Too much consumption is generally assumed for industrial and other night uses. Such should be determined, not estimated. In Oak Park the night rate, which is considered the waste barometer, was reduced from 56% to 21% of the average daily consumption in the four years between 1914 and 1918, inclusive.

The waste problem was attacked along various lines, some of which are not commonly associated with water consumption. The elements substantially affecting waste elimination as developed in the four years between 1914 and 1918, being these:—

1st. 100% meterage.
2nd. Efficient maintenance of meters.
3rd. Efficient complaint bureau, including education of consumers in cause and remedy of needless waste.
4th. Strict collection of high bills due to leakage or waste.
5th. Periodical waste surveys.
6th. Comprehensive and workable water ordinance, or rules and regulations, with their strict observance.
7th. Centralized control of the water department.

Meterage

With regard to the first item, 100% meterage, this means that all water pumped or otherwise delivered into the system is measured at the distributing point no matter where located. Included among the services metered are all municipal buildings, watering troughs, drinking fountains, street sprinkling, water used in parks, water used in the construction of houses and all dwellings regardless of size or character; together with fire hydrants when used for other than fire purposes. It is admitted that in the construction of buildings and in the case of fire hydrants that sometimes more water is wasted than is measured, but it was found that the moral effect of the meter had a great weight in minimizing the unlawful use of water. It is, in fact, a visible permit. Selective metering has been proposed and widely adopted in many large cities in order to reduce expense, but under that basis it would be necessary to meter only 10% of the Oak Park services, for Oak Park would be considered one of the good controllable districts adapted to periodical inspection, in a city like Chicago, for instance. Under this method, too, the wastage must have taken place before the necessity for stopping it will have become apparent.

Maintenance of Meters

The second item, the efficient maintenance of meters, is more important than appears at first glance. Meters should be repaired as soon as possible after being reported stopped or otherwise defective. This condition of the meter is usually detected by the readings, supplemented by observations of the meter reader. All suspicious variations in the readings, both high and low, should be investigated promptly. It has been found that frequent readings taken not less than four times a year, preferably more, gives satisfaction to the consumer in measuring accurately all the water that is used and in giving ample warning of unavoidable excess consumption. The periodical testing of meters, such as once every five years, has disclosed many unsuspected defects caused by undue wearing of parts, or the detection of tampering by the consumer. In Oak Park

the test of meters which were used by the private company preceding municipal management disclosed under-registration varying between 10% and 50%, with an average of 20% for the entire system. It was also found that in several cases where the bills were not high in spite of very small leakage that the meters did not register leakage as small as 30 gallons per day.

Complaint Bureau

The efficient complaint bureau, and the education of the water consumers, are important both for the satisfaction of the water-taker who tends to regard the meter with suspicion and for the peace of mind of the water department executive who realizes that it does not pay to antagonize citizens. The systematic handling of complaints is infinitely more satisfactory than adverse arbitrary decisions, or spineless methods of leniency caused by fear of political pressure or favoritism. Every high bill can and ought to be explained. The problem is really one of education. In Oak Park the campaign was begun by utilizing the backs of the water bills for admonitions to the consumer referring to the waste of water. This was supplemented by letters to each complainant with follow-ups in order to test the reduction in consumption after the repair of leaks. The meter readers report all suspicious sounds of running water, although not attempting to trace the cause to save time, and the rest is handled in the office by the complaint clerk. If the consumption is abnormal, a special call is made by a complaint inspector before the waste is brought to the attention of the consumer. It was noted that if notices were sent to the consumer before the investigation, he often repaired the fault and then insisted there must be a mistake or that the meter was incorrect, because there could be no leaks. Hence the adoption of a policy of locating serious trouble before reporting it.

No one in Oak Park has ever been obliged to stint in the use of water in order to receive reasonable bills. In fact the leaks consumed 3 to 10 times more water than the consumers themselves can actually use for all purposes. Our investigators proved that, in every case of that kind, there were toilets leaking at the rate of ⅛ to ½ gallon per minute. Sometimes the waste was so small that the watching of the meter did not readily indicate the quantity. Sound is really the best indicator of leaks. This is explained to the consumer who thereafter manages to use all the water he needs, although keeping down the bills. Often a warm meter advocate is thus obtained. It is always a good policy to give the consumer the benefit of the doubt and let it be known that the department is glad to correct errors. In many cases diplomatic cross examinations will uncover sources of waste which the consumers do not realize. It is dangerous to try to prove that the complainant is wrong until you can show him where. Rectify errors promptly. Service is the important element in popularizing the use of meters.

Aside from the waste through fixtures, high bills are caused by leaks in toilets, broken underground pipes in basements, defective toilet valves or ball-cocks, dripping faucets, thermostats, water motors, pumps operated by water power, defective stop-and-waste cocks, leaking valves, breaks in pipes under cement floors and between walls, water used for cooling food, water wasted to obtain a cool drink or to procure hot water from defective heaters, children leaving faucets open, lawn sprinkling with hose without nozzles, the flushings of water-closets uselessly after use for purposes for which they are not designed such as garbage receptacle, leakage through tanks in attics and by allowing water to run continuously in order to prevent freezing or into wash tubs or lavatories for washing purposes instead of filling the bowls or tubs before using.

Domestic Waste Detector

For cases where the department was unable to determine the cause of high bills owing to the fact that there was no leaking and that the consumer was sure he was not wasting water, a recording detector was designed, which when substituted for the meter gives a graphic record of the consumption for 24 hours or a week. This device consists of a piece of brass pipe ½ in. or ¾ in. in diameter and 7 ins. long, into which are inserted two brass tubes 1/16 in. in diameter, one pointed upstream and the other perpendicular to the axis of the pipe. For convenience these orifices or pitot tubes are soldered into ⅛ in. brass nipples. Two needle valves and strong rubber tubing complete the meter. A special type of recorder with a rapidly revolving chart so that drafts lasting only one-half minute could be detected, was constructed, which indicated at what time and how long faucets were left open for baths, for washing dishes or clothes, or for lawn sprinkling; how often toilets were flushed, together with a record of all leakage of 1½ gallons a minute or more. In fact, it was found easy to determine at what time the consumers arose and retired and whether they got up during the night or not.

First Apparatus Was Limited

The pipe, in reality a brass meter nipple into which are soldered permanently two pitot tubes, is inserted in the house service either in place of the meter or connected in tandem with it. In all, only two tubes were necessary for the range of consumption which exists between a four-room bungalow and 24-apartment building. In the first experiments the pitot tubes were connected to a mercury U-tube, by means of which rates ranging from less than ½ gallon per minute to 30 gallons per minute were measured by using the ½ in. and ¾ in. nipples. A camera provided with a revolving sheet of bromide paper, 3 ins. wide, was designed and adjusted so that the lens magnified the deflections through a slot about eight-thousandths of an inch wide. A pocket flashlight supplied the illumination, through a condenser, and the power was furnished by a single-cell storage battery constructed for the purpose. The only drawback to the device was that the high deflections were beyond the range of the slot, although small leakage was detected which the disc meter failed to record.

Will Detect All Flows

The next step, after fruitless attempts to alter the quantitative measuring device of the displacement so that it would register in gallons per minute, was to design a recorder which could take care of all flows. This new recorder will detect rates as low as 1½ gallons per minute, and there is no limit to the maximum recording capacity if larger meter tubes with lower centre velocities are used. The diaphragm is constructed of ⅛ in. mechanical rubber, and it is surprising to note the power transmitted through the stuffing box. The recovery after a short draft is rapid, even at maximum velocities. The recorder is not extremely accurate but frequent rating by means of the regular meter-testing outfit indicates that it is amply dependable. It has been used successfully in connection with a 2-in. Venturi meter, in making waste surveys by means of the hydrant and hose method, and gives much assistance in determining the varying consumption in the district tested, so that the leakage can be ascertained.

Plumbers invariably mislead the consumer by failing to appreciate small leaks and by discrediting the meter. But Oak Park water-takers are rapidly becoming educated in spite of this. After being shown repeatedly the waste which plumbers failed to locate, and seeing the effect of the stoppage of leaks which, according to the plumbers, could not amount to more than 10 gallons a month—they refuse to be sidetracked.

High Bills Caused by Leakage

Regarding rebates on high bills which were caused by leakage, we find that to reduce these indiscriminately is to defeat the purpose of the meters. As stated before, reliance should be placed upon educating the consumer rather than in the practice of allowing reductions in order to avoid adverse criticism or to satisfy some influential citizen. Water-takers easily fall into the habit of depending upon leniency if such is known to be a possible way out of their difficulties. The average consumer can bring the plea of first offense and a promise to be careful in the future. The way it works out though is this: If a rebate is allowed in one case, the tendency of the authorities will be known throughout the community in a short time, and it will be

very difficult to enforce payment of other similar bills. If a complainant feels that the water department is lax, he will not exert himself to keep his fixtures in repair. If, on the other hand, the water officials are known to be severe and exacting, and absolutely impartial, the majority of the consumers will be satisfied that there is an advantage in being on the alert. The minority, it is true, will complain and accuse the manager or other executive of unfairness, but the fact that everyone has been treated alike and that there are no favorites will permit a very successful operation of the "no reduction on account of leakage" policy. Oak Park speaks from experience. Better to allow a lower rate on the water, approaching the cost per thousand gallons in the case of unavoidable leakage; or else adopt a partial-payment plan or both. But charge for every gallon wasted. The lesson will strike home and be appreciated throughout the community.

Waste Surveys in Oak Park

In making waste surveys the most convenient method is to make, first, a rough survey of the entire city by means of the Pitometer. This is done by isolating certain districts by closing gate valves and measuring the supply through one of the mains left open to serve as a feeder. It is possible on small systems to make the preliminary test by shutting down those districts entirely for a few minutes, especially in the residential sections, and note the drop in the rate of consumption as indicated by the recording chart at the pumping station or reservoir or wherever the master meter may be located, providing it is on the distributing system.

It is often found, however, in districts which are completely metered that the velocity of the smallest feed main is so low that it is impossible to obtain an accurate record of the consumption if there are no large leaks. It is then necessary to by-pass the flow of water through a small pipe, 2 ins. or smaller in diameter, in order to increase the velocity. This is commonly called the hydrant-and-hose method because the most practical way of doing it is to feed from a fire hydrant, without the district, through a fire hose to a hydrant within the district. Oftentimes a regular displacement meter is used and the rate is obtained by noting the readings of the meter at regular intervals. This method is not a very useful one owing to the fact that several drafts may occur during the test. In Oak Park two other methods have been used: One consisting of a 2-in. Venturi meter with a ¾-in. throat which can accurately record rates from 3 gallons to 50 gallons a minute. The other is by means of Pitometers inserted into short pieces of pipe 2 ins. or smaller. Thus a quantity as low as ¼ of a gallon per minute can be measured.

Tests Made During Day

Contrary to the usual method of making waste surveys, all tests are made during the daytime, after determining the best hours in which the flow is somewhat steady, for inspection of the Venturi meter at the pumping station. The districts tested varied between ¼ of a mile and 2 miles in length. By being able to watch the rate of consumption, it is rarely found necessary to be on the job for more than half an hour at a time in order to determine the minimum rate of consumption.

The exact population of the district tested is obtained as well as the average daily consumption through the domestic meters—the former from the prevailing school census and the latter from the water accounts. Thus an estimate of the legitimate rate exclusive of the underground leakage is determined. In all cases where there is not much leakage the normal pressure is maintained through 600 ft. of fire hose. In order to bring the reading within the limits of the manometer where the flow is abnormal the valve on the meter is throttled. In one case a rate of 60,000 gallons per day at 10 pounds' pressure in a stretch of pipe only one-half mile long was observed, the normal pressure in the mains being 45 pounds per sq. in. Subsequent investigation by means of the aquaphone disclosed six service leaks which wasted water into the sewer at the rate of 200,000 gallons a day. This meant a leakage per capita rate of 305 gallons per day, while the service meters indicated only a total per capita consumption of 45 gallons, but after the repairs were made the leakage rate per capita dropped to 10 gallons a day.

Water Ordinance

In order to be able to operate the water department efficiently it is necessary that a comprehensive and workable water ordinance be adopted and followed to the letter. All the employees and officials should be able to follow a definite, unswerving policy with a minimum number of loopholes to be detected by skilfull lawyers. The water ordinance is either legal or it isn't. If there be a number of rules which have become a dead letter or are so ambiguous that the executive does not attempt to enforce them because he feels that they would not hold in case of a lawsuit, they had better be tried out immediately or else repealed. The efficiency of a water department is greatly impaired if there is a conflict with other city laws, as in the case of many municipal plants.

Centralized Management

Just a word on the final factor in the control of the water system. It follows from the foregoing paragraphs that all the divisions connected with the operation of large water departments must be under centralized management. It would be better if many municipal plants were made an independent branch of the municipal government. There would then be fewer failures in the operation of municipally owned utilities; failures which are concealed by taxes. There is a little incentive for efficiency in operation if the superintendent or manager makes a decision and is obliged to back down because the complainant is able to obtain a concession from another city official higher up, who is not vitally interested in the operation of the department. It is discouraging if the manager has outlined policies which resulted in a saving to the department and finds that the gains made are taken advantage of by some other municipal division which is not operated efficiently; or used because other funds have been exhausted. It is impossible to prevent needless waste of water against the advice of the manager, or if the manager is continually compelled to yield to pressure from some political adherent of the city fathers.

In the case of complaints on account of high bills, it is disconcerting to attempt adjustments and give satisfaction if the money is collected in one department, "shut-offs" for non-payment of bills handled in another and the meters read and accounts rendered in either of the foregoing or yet in a third one, all these different divisions being independent and under different executives. Unless all policies originate in the same department, there will be neither co-operation nor co-ordination.

The Canadian National Exhibition will open its gates August 23rd, but the formal opening will not take place until Monday, when H.R.H. the Prince of Wales will preside over the inaugural ceremonies.

The Jos. Dixon Crucible Co., of Jersey City, N.J., announces that for the past two years it has invested in Canadian government, provincial and municipal bonds all of its cash returns from sales of its products in Canada. This is an example which, if followed by all of the other American firms doing business in Canada, would be of benefit to Canadian finance. A. R. MacDougall & Co., Ltd., of Toronto, are the Canadian representatives for the Dixon pencils. The Canadian Asbestos Co., Montreal, are the representatives for the Dixon paints and lubricants.

The enforcement of regulations governing the practice of surveying and civil engineering in Idaho now comes under the Commissioner of Law Enforcement, R. O. Jones, Boise, Idaho. There is now a law regulating the practice of civil engineering in Idaho which appears to include all branches except mining and metallurgy. Examination for civil engineers will be held the second Tuesday in September; for surveyors, the first Tuesday in September. No survey of land or plat of same has been legal since June 1st, 1903, unless made by a licensed surveyor.

THE RELATION OF THE ENGINEERING PROFESSION TO ENGINEERING EDUCATION*

By Frederic Bass
Professor of Municipal and Sanitary Engineering, University of Minnesota, Minneapolis, Minn.

ENGINEERING education must meet the demands of the engineering profession, not only those demands which have been given definite form, but also those which now inarticulate, are struggling for expression. Professions come into being in response to great human needs; and are endowed with vitality and life in proportion as they minister to those needs. The engineering profession is youthful, it has lavished the service of its constructive genius upon a waiting world, and a new order of civilization has evolved with a rapidity unknown in other ages. Men have been given suddenly, within a few score of years, new wealth and power which has brought their minds into contacts a thousandfold multiplied beyond previous experience. In the last four fateful years, new groupings have been formed in unforeseen environments with still further acceleration. The world is now confronted with the problem of quickly adjusting itself to the conditions which are inexorably imposed upon it.

No Clear, Determined Declaration

The question in the minds of men is: Can we meet the situation and master it? The questions in the minds of engineers are: What part is it that the engineering profession must play? Are we going to meet our problems and master them as we have in the past? Are we going to realize this supreme opportunity and marshall our strength to grasp it? If we are, how is it to be done? Were the answers to come from any one of the great number of engineers whose hearts beat for their country and whose minds have grasped its peril, there could be no doubt as to its nature. But how about the answer from the group, from the profession as a whole? What do we hear? One voice loud, emphatic and clear? A babel of sounds from an eager multitude? Or only faint murmurings from the ranks here and there?

We can all agree that no clear, virile, determined declaration has come in unison from the profession, for it is relatively young and does not yet know its place in the world; it has not had the experiences and grapplings with life that alone can teach its true place, its duties, its privileges, its limitations and its power. Time and trial will bring it to a realization of these, a realization that will be splendid and magnificent.

Secondary Positions at Best?

The voices that are heard here and there expressing the hope, and even the confident expectation of the future, are becoming more numerous. They come from the local societies, from the state societies, from the older national societies. As their volume swells, the time for action nears, and in action, clear-headed leadership must be had.

The question might be asked: "What has this history and this concern for the destiny of the profession to do with education?" It has everything to do with it. The students of the engineering schools of to-day will constitute the fibre of the engineering profession of to-morrow. When the choice of a vocation presents itself to a young man, he asks: "Whither does it lead? What tasks await me there? In what company shall I find myself? Am I to be a slave or a servant, or am I to be a master? Am I to be in a position where my constructive genius, whatever it may be, shall lead me to a position where my works shall demand and receive their just recognition, or shall I forever hand the fruits of my labor to others who knowingly or unknowingly shall profligately waste them or throw them aside?"

What is the teacher to answer the boy? Can he point to a life of magnificent service, full of experience, rich with all the associations that the highest type of human being desires, a life in contact with the really great human developments? Or must he answer that engineering organization is weak, that, if he takes up engineering as a life work, he will always be the servant of others, at most, in a secondary position; or, if he finally wins a high place, he will have to fight alone?

The replies to these questionings are to be found in the places where practicing engineers are found, in the character of the profession and its relations with other groups and the general public. As a spring of water rises no higher than its source, so no body of men can rise to greater heights than the individuals which compose it, and if the profession of engineering is to be what its best friends hope it shall be, then it must make such answer to the questionings of youth that shall attract to it the young men of high ideals, of clear mind and vision, of determined purpose; the men who shall be neither servants nor slaves,—but masters of their work. These questionings of youth constitute a direct challenge to each one of this body.

Let the Engineers Lead!

The first requirement in teaching or in any other form of directing men's minds and hands is to give to them a clear, definitive objective, and so it is that the greatest factor in intelligent, fruitful and efficient teaching lies in supplying the motive force a reward for accomplishment. Given that, the problem of teaching is one of direction, and not one in which the teacher must use his energy in forcing unwilling minds to grasp ideas, theories, applications of theories and facts which seem to be devoid of interest. A foreman or superintendent who must continually, with his own hands, do the work of his gang or his force is not the man to produce results. He must keep his attention on all his men and their tasks, encouraging, checking, taking advantage of occurrences and co-ordinating the efforts of all. So must the teacher work, and his students, like the men under the foreman, must receive the inspiration of a clear objective and definite progress toward it, even though the objectives be unlike in character and in degree of remoteness. The engineers of America hold in the hollow of their hands the future of their profession. Let them set the mark, let them demand results from the schools, let them lead and they shall not be disappointed in their followers who themselves, some still better day, shall be the leaders.

New Ideals Affect Curricula

The formulation of ideals and aims and the definition of the fields of activity of the profession would also prove a valuable standard by which engineering curricula might be judged, and according to which all of the separate courses of instruction might be correlated. Such co-ordination both within the schools and without would seem to be a fair primary requirement in education, yet only rarely is such an ideal approached. In many institutions there are inconsistencies in the curriculum, frequent, unnecessary duplications in instruction, omissions of important fundamentals, inclusion of irrelevant subjects, caused on the one hand by slavery to precedent, and on the other by undue susceptibility to fads, both of which exercise influence in the absence of a comprehensive understanding and vital faith in the future of engineering.

This question of curriculum is important; upon it depends to a large extent the equipment with which the student must tackle his job when he graduates. It is fairly uniform throughout the engineering schools of North America, although many variations do exist. All engineering schools require practically the same courses in mathematics, rhetoric or English, mechanics, physics, chemistry, drawing, shop surveying and the various applications of theory to practice, such as machine shop design, steam engines, electrical machinery, structural design, hydraulic and sanitary engineering, railroad engineering and the like. The general assumption among engineering educators is that engineering is almost entirely a technical pursuit, that its foundation lies in an understanding of the forces of nature and their mathematical expression. Observation of engineers' *work* indicates that in the great majority of cases this assumption fits the facts, and that it will continue to do so to some extent, but the conception of the engineering profession which is taking form in the minds of thousands of engineers to-day is a much greater and higher one, and the curriculum must conform to it and will when engineers definitely demand that it be done and see to it that it is done.

*Address to the American Association of Engineers.

It is the engineer's duty in design to plan not only for the present, but for the future; he is coming to see that the structure of his professional organization, while adequate for the past, is being overloaded, and must be reconstructed to take care of future loads; he is about to design a new structure. Engineering college faculties must recognize this and so plan their curricula that the foundations shall include not only the principles of physics and chemistry and methods of mathematics, but those of the basic nature of the human institutions by whose agency and through whose processes the service which the engineer has to offer may be made to bear fruit. The student of engineering must realize this; he must know that his task is to be a more serious one than that which his predecessors faced.

Teachers Should Work "Outside"

The engineers of this country are now beginning to realize their lack of unity. A number of experiences have brought it home. It is perfectly apparent that when a desirable public improvement, either in political method or in application of method to any particular object is to be made, that the advocates of it will have a greater chance of success when their case is well studied and prepared, and when their forces are marshalled so that at the opportune time the final blow can be given with the concentrated power of all. So in the administration and conduct of an educational institution it is important that the members of the faculty agree as to their aim and methods, and can concentrate their force upon their common object. This involves the question of teachers, their organization, and the spirit which drives them on. Some colleges, often for very good reasons, take their own graduates in as instructors, thus losing the advantage of minds with a new viewpoint. Other colleges discourage professional practice among the faculty and thereby tend to divorce the college from the world of action. The most vital requirement of a technical college is that the members of its faculty have at least a sympathetic appreciation of the character of the practising engineers' problems even if it is not possible for them to personally engage in practice themselves. Certain teachers of applied science should be *required* to do some professional engineering work. It is often forgotten that a large percentage of the teachers of engineering students, in language, rhetoric, physics, mathematics and mechanics and drawing, have little or no connection with or knowledge of engineering methods or engineering organization. A still larger percentage are entirely beyond the reach of the renaissance of spirit now manifest among engineers. This problem of keeping the teacher in close connection with the developments of engineering, not only technically, but socially, is fundamental. Every teacher of engineers should be affiliated with at least one national engineering association, the ideals and activities of which are not bounded by too narrow an outlook.

Students Benefited by Discipline

In spite of all that may be done to lead the student to self-help aroused by interest, there must still be some work done because the teacher orders that it shall be done. There must still be some things taken on faith. For this there must be discipline. No system of education can be devised which can rely wholly upon the student's own initiative to maintain order and progress. The statements already made should not be construed to mean that the standard of work, both in quantity and quality should be determined and maintained by the student's interest and not by the teacher; that is the teacher's first duty. A brief period of experience with the Students' Army Training Corps, in which the writer had 900 students in surveying, convinced him of the desirability of a stricter system of discipline among students. The average college student will *not* map out his time so that it may be usefully employed; the army discipline did that for him. He will not generally show the regard for property and persons that is required of students at West Point. There was a noticeable improvement in this respect during and immediately after the recent military training period. While the writer is not willing to see military training in such a concentrated dose again administered to the colleges, he does heartily believe that the average college student would be immensely benefited personally by a strict discipline, not only while under it in college, but afterward. There would be taught the value of courtesy and perhaps of the deeper meaning of courtesy, which is understanding and tolerance of and respect for other people as well as himself. We all recognize the results of it in the splendid officers of the United States army and the navy.

There has been considerable discussion lately in regard to marking systems. Psychological tests for various reactions have been suggested as a substitute for numerical grading of scholastic work. While the writer has only a reading acquaintance with such tests, he believes that after a teacher has come to know the individuals in his class, he unconsciously treats them according to their mental constitution, and as long as his final grades do not entirely depend upon answers to formal questions, they will represent a fair rating. It is not to be doubted, however, that an analysis of the men in a class according to a correct psychological score card, would assist any teacher in a mere accurate estimate of each student's personality and the rate at which he is developing his powers.

A Threatening Development

To summarize here the points which have been mentioned: First, the engineering student must have an ideal which offers an opportunity of realization and which is worthy of the effort of the highest type of man; this ideal must be set for him by the engineers in practice. Second, the engineering curriculum must provide the student with a thorough grounding both in the fundamental principles of natural law and of human institutions. Third, the school must have a faculty in sympathy with the great body of practising engineers, organized themselves with a common purpose to develop every student so far as possible, and to make of him a master of what little he can compass in his college course. Fourth, a certain discipline which shall demand a high standard of personal conduct. With a high ideal, an adequate curriculum, a well organized faculty in touch with the profession and sufficient discipline, the school can perform its duties.

There is one development which threatens the engineering school. Colleges of arts and sciences and of commerce are beginning to recognize the need of the business man and the man of general education for a more definite purpose in his courses of study, a need for those departments of knowledge of which the world is going to demand much; among these, the fundamentals of engineering. If engineering colleges do *not* meet the demand for a broader fundamental training, we may expect to see men choose the courses in the colleges of arts and sciences in which engineering principles are taught, and the engineering colleges continue to hold only the men who wish to confine their interest to strict technical details. If such a development attains any considerable volume and momentum, there will be many college graduates wth insufficient engineering training, attempting to enter engineering practice, men whose teachers have still less sympathy with and knowledge of conditions of practice than those of engineering colleges, and who can be reached and influenced by engineering organizations only witb the greatest difficulty.

Committee on Engineering Education

The whole future of engineering education lies with the profession. When engineers have formed an inclusive national organization that can speak as the voice and authority of a great profession, whose mission is to create and conserve wealth and to demand a higher type of human accomplishment and civilization, the public will listen; financiers, farmers, skilled and unskilled labor will give ear, and order and justice will more and more prevail in the affairs of men. Engineers must first set their own house in order. Only by intense and prolonged study and planning can they do that first task and only by ceaseless vigilance can they maintain it. The labor involved is great and must be divided; it must be done by well chosen committees fully cognizant of the portent of their work. Among these the writer would wish to see a committee on engineering education, well provided with funds to diligently prosecute its labors.

The Carnegie Foundation for the Advancement of Teaching has enabled a notable investigation and report to be made upon the subject of engineering education. This report, admirable as it is, is but a beginning. Such investigation and inquiry should be continuous and more general. The advancement of teaching of engineers means the introduction into the engineering profession of a higher type of man, and this strengthening of the engineering profession means an indefinitely better service to all men.

On the other hand, this same agency has devoted enormously greater funds and efforts to pensioning aged professors. Pensioning means decreased salaries. It is merely a system of enforced saving. It is in this case gratuitous and insiduously undermines independence and self-respect, and is hence essentially a hindrance to the advancement of science. If an agency instituted for promoting education can be found to donate millions for a mistaken method, can one not be found to promote a true method, to promote an inquiry into the problem of attracting to engineering the most promising youths, who shall devote themselves to all the finest and greatest things that engineering includes?

DETECTION OF WATER WASTE*

By L. G. Denis
Hydro-Electric Engineer, Commission of Conservation

THE absolute necessity and great value of taking means to detect and control water waste in a water supply system are being more and more clearly demonstrated. The special means now available for this purpose, when applied to a system operated as was customary in the past, invariably reveal and locate numerous wastages and losses, allowing these to be easily checked and curtailed.

A striking example of what conditions may exist in other systems is given by a municipality of some 30,000 population in the state of Ohio. A recent survey by professional water savers resulted in the curtailment of the total water pumped by more than one-half. This may at first seem an exaggerated statement but an analysis of the various losses revealed and stopped shows that it is quite within reason.

As is usually the case, the losses were principally due to leakage and illegal consumption. The illegal use detected was very large and practically confined to one consumer, a bottle works, the water being taken through a covered connection to the fire line for the property. The company disclaimed any knowledge of the connection although it was being used by them regularly for cooling purposes.

The following shows how the daily consumption was reduced:—

Consumption before survey	3,932,000 gals.
Consumption after survey	1,845,000 gals.
Decrease	2,087,000 gals.

The decrease was made up as follows:—

Leakage detected and stopped	692,000 gals.
Illegal use stopped	895,000 gals.
Unaccounted for	500,000 gals.

The "unaccounted for" decrease of 500,000 gallons was attributed by the experts to the voluntary action of an illegal user who feared detection. That is, it was assumed that another large consumer became aware of the investigations and discontinued the illegal use of water before detection.

The costs in connection with the above-mentioned survey are also interesting to note. The contract price for the entire work by the experts was $2,600, while the extra expense incurred by the municipality in connection with the survey is estimated at $2,600 more. On the other hand, the company caught using water illegally offered to settle for $6,700 in payment of the water used, but the municipality is suing them for $49,000.

*From "Conservation."

REGIONAL PLANNING OF THE NIAGARA DISTRICT*

By Thomas Adams
Town Planning Adviser to the Housing Committee of the Dominion Cabinet, Ottawa

IN order to plan our cities and towns properly we must investigate and analyze many problems which have a bearing on life and growth within and surrounding them. What is true of the individual is still more true of the city. It cannot and does not live to itself alone. Recent events throughout the world have shown the extent to which the town and the country are inter-dependent. Recent tendencies in industrial decentralization have also shown the importance of one of the modern aspects of town planning, namely, the direction and control of the growth taking place within the rural and semi-rural districts where new industries are being established. The artificial boundaries of cities are becoming more and more meaningless. The real controlling factors which determine and encourage industrial growth are physical and natural to a greater extent than they are administrative and artificial.

Regional Survey and Plan

One of the difficulties in dealing with this subject is that we have not yet adopted a clear and unambiguous terminology. The same words have different meanings to many of us. I must, therefore, begin by explaining what I mean by regional planning and regional survey, and I will take them in the logical order:—

1. The regional survey bas to do with the investigation and mapping of the existing physical, industrial and residential features of a region that has interests and problems in common, which needs comprehensive and co-ordinated treatment without regard to arbitrary administrative boundaries.

2. The regional plan is concerned with the general planning of the area included in a regional survey. It is a skeleton and tentative plan of a region within which there is comprised a series of municipal units, in juxtaposition to one another, and having overlapping and inter-related problems. The width, direction and classification of our main and secondary highways should be governed by the needs of such a region and not by the needs of one municipality within it. This principle is fully recognized in Ontario highway legislation, in regard to the principle on which the cost of construction is apportioned. The planning of our system of communications in the regional plan should also have regard to the classification of land for different purposes of industry or residence. Land should be classified in a general way for industries, for residences, and perhaps for agriculture, for park areas or for special reserves or as unsuitable for building purposes. We would also consider within the region how far it is desirable to prescribe a code of housing and town planning regulations to deal with building conditions that need to be dealt with in common over large areas of different character. Sewerage and water supply may have to be dealt with in large regions to obtain efficient and economical schemes in cases where it is not practical to get an efficient system of either in separate units of administration. These and other problems that can be dealt with in a preliminary and general way need regional rather than municipal treatment.

The Town Plan

3. The town plan is the definite plan, accompanying a definite piece of legislation, for fixing within the city or the county areas first those parts of a regional plan which are locally approved, and secondly, the civic design and regulations dealing more intimately and precisely with the problems connected with the growth of the town, its means of communication, its industrial development, its residential areas, its character and density of building, etc.

We thus have three distinct processes, each connected with one another, and logically leading up to one another, which are the regional survey, the regional plan and the

*Address at the National City Planning Conference, Niagara Falls, N.Y.

civic plan. It is unnecessary for me to argue with town planners how hopeless the task is to attempt to prepare a plan without having obtained accurate data regarding existing physical and industrial conditions.

The Niagara District's Problems

The Niagara district seems to me to be one which needs the making of a regional survey and a regional plan as a preliminary to a series of civic plans for its city, town and county areas. Neither Buffalo, nor the Tonawandas, nor Niagara Falls, are strategic centres; they are parts of a strategic centre of 1,000 square miles in extent on both sides of the Niagara River. The problems of this region are international, and give us proof that the power of natural conditions is so great that even the boundaries of nations do not form intelligent and appropriate boundaries to regional and town planning schemes. Indeed, may we not hope, that in the process of planning them we shall help to knit these two nations, their industries and people, closer together; and also that the bridge which we propose to erect as a symbol of peace will be more than that—will be a symbol of co-operation and mutual respect? Personally, I should like to see something more than a physical bond, such a bond as could be provided by a Regional Planning Commission representative of the State of New York and the Province of Ontario to deal with the planning problems of the Niagara district. That need not be an idle dream any more than the creation of an International Waterways Commission.

Superficial study of the problems which need to be dealt with within the Niagara region has convinced me that the whole district, for at least 20 miles on either side of the Niagara River, needed to be made the subject of a regional survey. The Niagara district is one with enormous potentialities for future commercial development. It has a strategic position of great importance to both our countries, and it has certain advantages as a tourist centre which are sufficiently in conflict with the aims of those who are interested in its industrial expansion to make it important that a survey be made before any definite plans are adopted by any municipality within the district.

Area and Population

What I call the Niagara District comprises approximately 20 miles on either side of the Niagara River for a length of 28 miles between Lakes Erie and Ontario. Further west in Canadian territory another regional area has the city of Hamilton for its centre. In the United States the area covers all the county of Niagara with the exception of the towns of Somerset, Hartland and Royalton, and in county of Erie includes the towns of Tonawanda, Amherst, Clarence, Cheektowaga, Lancaster, West Seneca and Grand Island. The total area is over 700,000 acres, of which about 317,000 acres are in Canada and 418,000 acres are in the United States. The present population is estimated at about 751,600, made up of 86,700 on the Canadian side and 604,900 in the United States. Buffalo is not the geographical centre of the region, although it is the predominant partner among the local units by reason of its size. Further consideration might lead me to include more of the southern environs of Buffalo to a distance of 10 miles from its centre.

Including all towns of less than 7,000 population, the rural population on either side of the border is about directly proportionate to the rural area, being about one person for a little less than seven acres on the Canadian side, and one person for a little over six acres in the United States. The densities of Lockport and the Tonawandas are very low, being only about 4.5 persons and 2.7 persons respectively per acre. An estimate of the population gives 1,170,000 for the Niagara frontier regional area in 1950. It has been considered that the rural population would remain unchanged, and the estimate has been based on future growth curves of the combined total of three Canadian cities in the region and six of the regional cities in the United States.

Consolidation Desirable

A study of conditions shows that cities are growing along the Niagara frontier and the Welland Canal, so that their boundaries are being forced out to meet the smaller towns. For example, Lasalle is now really a residential part of Niagara Falls, N.Y., but Niagara Falls has no control over its development, although the boundaries of these two places are now adjacent. Consolidation is considered desirable in these places as well as in St. Catharines, Merriton and Thorold; Lancaster and Depew, partly industrial and partly residential, have similar problems; Bridgeburg and Fort Erie, Port Colborne and Humberstone are other cases in point. Then there is the larger question of what areas will soon be incorporated in the city of Buffalo. Evidently there is great need for some definite control over suburban areas, or looking further into the future, areas that are to become suburban areas, and eventually urban areas.

Purposes and Problems

For what purposes do we require more accurate information, and what are the usual problems that have to be dealt with in planning a large region? We may summarize these purposes and problems as follows:—

1. Industrial development—including the arrangement and classification of all lands and the location and distribution of manufacturing plants.
2. Economic use and regulation of the sub-division of land and the character and density of structures in rural and urban areas.
3. Housing—sanitation, convenience and amenity.
4. Transportation—railways, highways and waterways.
5. Sources and distribution of power.
6. Water supplies and sewerage.
7. General amenities—including parks and boulevards and development of tourist facilities.

I will now proceed to consider some of those principles in relation to the problems of the Niagara district.

Industrial Development

In the Niagara district the varied character of the soil and its great fertility in the rich valleys, make it of special importance that the system of distribution should be of the best kind to encourage the maximum of agricultural production. Being an old settled region it is probably impracticable to carry out any schemes of re-planning or re-classification of the lands. It is in connection with the growth of manufacturing industries that the chief problems occur. The combination of cheap power, adequate transportation facilities, and reasonably priced land are having their effect in promoting rapid manufacturing development in the region. As an example the town of Welland had only five factories five years ago and now has thirty. In the cities and towns on the Canadian side there are 145 manufacturing establishments; and on the United States side, 183 outside of Buffalo. The manufacture of cereal foods and the canning and preservation of fruits and vegetables are carried on side by side with the manufacture of aluminum, calcium carbide, etc. Too little regard has been paid even in recent years to regulating the location of objectionable industries, and great and perhaps unnecessary injury has been caused to the great asset of scenic beauty possessed by Niagara Falls. The need for zoning is evident to the casual observer; the methods of carrying it out require prolonged study so as to avoid injury to industrial development.

The low-lying land to the north of the escarpment and also including the area for a few miles south of the escarpment on the higher land is excellent soil and well suited for fruit farming. The balance of the region is only at Lake Erie level, and presents some drainage problems, especially in the clay strip that runs through the centre of the region. On the Canadian side, near Lake Erie, shallow soil is also encountered, with limestone outcropping near the surface, and peat bogs are also encountered. Generally speaking, the level area which is given up to dairying and general farming, has not been developed up to the possibilities of the soil.

Housing Situation

Generally speaking, no protection is afforded to residential areas in the region, and sanitary conditions are defective in districts occupied by workingmen's families. There is an estimated shortage in the cities, not including Buffalo,

in the region of about 2,350 houses. Taking the figure of 2,350 as the shortage in houses and an estimated population of 168,000 it will be found that for every seventy people there is another house needed.

A survey of housing conditions is needed not only to ascertain facts with regard to the shortage, but also to find out the best means of raising the standards of existing dwellings and improving sanitary conditions.

Railway Situation

The numerous railways that serve this area make it a great railway centre, and perhaps unrivalled for rail transportation faciilties. At Gardenville gravity freight yards, near Depew, some $25,000,000 is to be spent, and the yards completed in the next ten years; $6,000,000 has already been appropriated.

At the Lake Erie end of the region there is only one railway bridge, and that single tracked. Trains are said to cross at the rate of one about every seven minutes, and there are 15,000 cars of merchandise passing through every month. The C.P.R. may consider it desirable to build bridges at Goat Island to cross the Niagara River and give them their own bridge entrance into Buffalo.

As far as the cities and towns are concerned, the greatest problem is that of grade separation. In this matter the railways have had the upper hand in the past, and it is time that the general interests of the public were safe-guarded in connection with railway enterprises to a greater extent than hitherto. But it is not the railway corporations that are to blame; the fault lies with the local authorities in not taking action in time. Portions of Niagara Falls, Ontario, and Niagara Falls, New York, are practically devoted to switching, and this right on some of the busy streets. For example, in Niagara Falls, Ontario, there are 14 level crossings. It would be an advantage to have the tracks of the electric radial railways moved from the central streets of cities and towns in certain cases. In other cases, streets are too narrow for double tracking.

Highways and Waterways

Even a preliminary survey of conditions on the Canadian side, across from Buffalo, would seem to indicate that that area is being hampered in its development by the lack of a highway bridge. A "peace bridge" has been proposed as a memorial, and it is stated that bills are now before the governor of the State of New York, one for a bridge at Buffalo, and one for a bridge at Niagara Falls. Apart from the question of the peace bridge, there is no doubt as to the need for a bridge at Buffalo across the Niagara River, but the means of communication on both sides of the river need to be studied before the site of the bridge is settled.

The Niagara River, as a waterway between Lakes Erie and Ontario is, of course, impossible for navigation. On the Canadian side the Welland Canal provides a waterway between the lakes.

The great improvement which is taking place in regard to the waterways which feed the district will be certain to greatly increase the population and industries of the region in the near future, and they will also tend to create changes in regard to local conditions of development and settlement of land. A regional survey and plan is needed to deal with expected growth and change of conditions, even if no other development of transportation facilities were taking place. It is also important, as we shall see later, to consider the park system of the region, and perhaps the drainage system also, in connection with the abandonment of old waterways.

Power Situation

The rapidity with which the demand for electrical energy has grown is indicated by the fact that the first modern power development at Niagara Falls took place in 1890, with an initial installation providing for the production of 100,000 h.p. At the present time the total production is 650,000 h.p. At Power Glen, adjacent to St. Catharines, there is also a development of some 52,000 h.p. There is also under construction a plant to produce an additional 400,000 h.p. The principal development is that of the Hydro-Electric Power Commission of Ontario, which is constructing a canal 8½ miles long to divert the flow of 10,000 second ft. of water and provide for the ultimate development of 300,000 h.p. at Queenston. This enterprise will cost $25,000,000, and will not be completed until 1921.

There has been some criticism of the construction of the open cut, which is having an injurious effect on adjacent property, and will make the city of Niagara Falls, Ont., an island. Whether this criticism is justified or not, and whether part of the canal should have been in tunnel, as apparently would have been practical, does not concern us, but the fact that it is made shows that no such scheme should be carried out without careful study of all the factors, including those outside the purview of the hydro-electric engineers, before this kind of enterprise is begun. The day should be past when great corporations, whether railway or power companies, should be permitted to ignore the effects of their enterprise on the industries, property and lives of the community as a whole.

Water Supply and Sewage Disposal

Lake Erie is the source of water supply for the urban population in this region, water being obtained either via the Welland Canal or the Niagara River. There is pollution of the Niagara River, practically none of the cities or towns treating their sewage. This pollution will be increased, with the completion of the Welland Ship Canal and the entrance of the water from the Welland River into the system. It has been decided to have a pipe line extending from Lake Erie to Lake Ontario to supply the cities and towns along the canal.

The Tonawanda Chamber of Commerce is considering a scheme of sewage disposal for their whole area. F. W. Barrally, city engineer for Tonawanda, has done some preliminary work on this scheme which, it is claimed, provides for sewage disposal and drainage of the outlying area along the Niagara River, and incidentally for the development of power. It would avoid the very serious pollution of the Niagara River, and would use the old Erie Canal as a drainage canal for sewage from Buffalo to Tonawanda. There is urgent need for study of the sewage disposal problem of the whole district so as to get an economical and efficient system.

Parks and Tourists

Both the rural and urban areas seem to be deficient in parks. It might almost be stated that the cities and towns have no parks. An estimate had been made that from 1885 to 1907, 15,000,000 visitors have viewed Niagara Falls. In spite of all that has been done, it cannot be said that sufficient care and vigilance has been taken to preserve the remarkable scenic beauties of this region, or to regulate industrial development so as to prevent injury to the amenities of the district, with loss of convenience or efficiency. The commercial value alone of the great combination of natural and historic features is such as to justify the expenditure of more money and effort in conserving them. At old Niagara, with its large "Commons," there are points of historic interest, and the ruins at Fort Erie at the southerly end of a possible park system should also be preserved.

But it is a regional and not a local problem. The district has been endowed by nature with exceptional gifts, extensively as well as intensively. People should be attracted here to spend days instead of hours. All these matters I have referred to, create one big problem that requires big men to solve it and raise it above the level of the politics of the village pump. The whole question of the development of this region in all of its ramifications is big enough to be dealt with internationally. As an immediate practical measure I suggest that a permanent conference or a joint town planning commission of representatives of all the municipalities in the region, be created to prepare a regional survey and a general plan for the area; that federal, state and provincial aid be invited towards the preparation and carrying out of a comprehensive scheme. This need not be done in any way that is unconstitutional, or so as to interfere with local autonomy. It need not involve that any municipality now engaged in preparing its own scheme suspend its operations, but merely that it recognizes that it is only part of a greater whole, and that whatever it does should be made to fit a regional plan.

COST AND SERVICE OF NEW YORK STATE HIGHWAYS*

By George C. Diehl
County Engineer of Erie County, New York

ESSENTIAL elements in the costs of highway transportation are the cost of road construction and maintenance, and the cost of vehicle construction, maintenance and operation.

The first two costs are primarily the concern of the highway engineer. In these days of million and billion dollar expenditures, there is a tendency to expend fabulous sums for permanent highways, so-called.

Of course, every highway engineer is well aware that no road surface is permanent, and the time is sure to come when a new surface must be constructed.

The actual annual cost of a highway includes the yearly interest and sinking fund charges, the yearly cost of maintenance and the yearly allowance to provide a resurfacing fund.

Interest and sinking fund requirements cease when the honds mature, but this is often from 30 to 50 years, and for that period, at least, should be included; and at maturity it is difficult to foretell road requirements and problems.

Large sums of money have been squandered in the construction of too expensive highways, as well as in the failure to provide sufficient funds.

Accurate Statistics Needed

Sooner or later, every wasted dollar must be made good —generally by the consumer, who staggers under high living costs, and is apprehensive lest there be no check in rapidly mounting prices. The only sure remedy is to practise economy, particularly in the disbursement of public appropriations, knowing that every dollar saved helps lift the burden. Accurate statistics, comparing tonnage, construction, maintenance and financing costs, would help to determine sound highway policies and proper types of construction, including widths, cross-sections and materials.

Unfortunately, such statistics have not been gathered, but a systematic record of costs and travel should be outlined and comparative figures collected which would be of great value in a year or two, and absolutely indispensable after a term of years.

New York State has expended more money than any other commonwealth in highway construction and has the greatest mileage of connected improved roads, so that her experience is of value in considering the highway problem.

There cannot be much doubt that an expenditure of $50,000 to $60,000 a mile is required, and would be justified on the main highway from Buffalo to New York, and possibly on a few other important trunk lines. It is equally certain that expenditures of upwards of $30,000 per mile would be grossly extravagant on a great part of the state and county highway system, and that $15,000 per mile would be far too much to spend on the preponderating majority of lateral roads.

A prominent highway official recently stated that every mile of road in the state should be of a type costing at least $30,000 per mile. There are 80,000 miles, and this plan would require $2,400,000,000—so impossible that discussion is unnecessary.

All Macadam at Start

Starting in 1898 with an appropriation of but $50,000, which was supplemented by an equal amount by the localities, the state engineer improved about 12 miles of highways with water-bound macadam at an average cost of $8,000 per mile. This type of pavement was specified almost exclusively until 1909, and 2,000 miles were constructed during this period at an average cost of about $9,000 per mile.

In 1909, the State Highway Commission was created, and about the same time motor vehicle traffic began to increase very rapidly, and other types, such as the asphalt macadam, both penetration and mixed methods, and brick block, became quite common. In 1915, about 61%, and in 1916, about 46% of the state projects provided for the water-bound macadam type of pavement, and a total of about 3,560 miles of this class of pavement was constructed.

Many of the older water-bound macadam pavements which had been constructed on the main routes have been resurfaced, and in some instances reconstructed with more substantial pavements. By reference to the State Highway Bulletin, just published, it can be noted that about 1,040 miles of these pavements have been resurfaced, about 205 with the same type, 810 miles with asphalt macadam, penetration method, and 25 miles with asphalt macadam, mixed method; and about 125 miles have been reconstructed, 67 miles with new concrete pavement and 58 miles with new brick pavement, leaving about 2,600 miles of water-bound pavement still in the state system.

Resurfacing and Reconstruction

New York State, in building water-bound macadam pavements continuously for 20 years, to the extent of 3,560 miles, has found it necessary to reconstruct with a pavement of a radically different type 3½% of the total, and resurface with a new top course of macadam, using the old pavement as a foundation, about 30%.

During the first ten years of state highway improvement, 1899 to 1908, no maintenance was provided by the state, but the law provided that the maintenance should be performed by the towns. In 1909, state maintenance work and supervision were instituted. The water-bound macadam pavements have accordingly been separated into two groups. Of the 2,000 miles of water-bound macadam constructed from 1899 to 1908, and upon which maintenance had been neglected, about 860 miles, or 42%, have been resurfaced and reconstructed. Of the 1,560 miles constructed between 1908 and 1918, about 180 miles, or 12%, have been resurfaced or reconstructed.

With modern conditions of traffic, where motor vehicles predominate, water-bound macadam can only be maintained by surface treatment of asphalt or tar. With the light, cold materials and heavy traffic, the surface treatments are required every year, while with average traffic the treatment may be omitted about every third year.

When the surface treatment is delayed beyond the proper time, surface holes develop rapidly and constant patching is required.

In 1909, the state first undertook the construction of the asphalt macadam, penetration method, and this pavement soon became the prevailing type for the main through and market routes.

The state system now includes about 3,000 miles of this type, of which about 850 miles are old, water-bound macadam, gravel and second-class concrete pavements which have been resurfaced with a new asphalt macadam top course, laid over the old pavement as a foundation.

Maintenance of Asphaltic Macadam

It is significant to note in the bulletin that of the 3,000 miles that have been so constructed, it has been found necessary to reconstruct but about 10 miles, or ⅓ of 1%, with a pavement of different type. About 8 miles have been reconstructed with concrete pavement and about 2 miles with brick pavement. One hundred and ten miles, or about 3⅔%, have been resurfaced with a new top course of the same type. Many of these pavements have been subjected to nine years of traffic and are in perfect condition to-day, resembling sheet asphalt.

Little maintenance is required for asphalt macadam pavements for the first three or four years after construction.

About four years after improvement the pavements are given a surface treatment of light asphaltic oil, which acts as a flux to the asphalt in the macadam, which works to the surface and is distributed by traffic, to the extent that

*From "Good Roads," New York.

the seal coat is renewed, and under ordinary conditions another treatment will not be required for at least five years after the first treatment.

Little or no trouble is experienced by pitting or raveling, and the pavement will stand considerable neglect without serious deterioration. The cost of maintenance for the first three years of ten asphalt macadam pavements, selected at random, aggregating 54 miles, is found to be $180 per mile per year.

Bituminous Veneer on Concrete

During the period from 1912 to 1914 there were constructed about 300 miles of second-class concrete and Hassam concrete, with a light, bituminous surface, generally of tar.

These types have not given satisfaction, as the concrete does not sustain traffic without disintegration unless protected by a bituminous mat. This light veneer surface of bituminous material is with difficulty maintained, and constant patching of the surface is required. These pavements have been covered with a course of asphalt macadam as fast as funds would permit, and about 40 miles, or 13%, of the total have been so treated, about 24 miles having been surfaced with the penetration type and 16 miles with the mixed method of asphalt macadam. These types were discarded in 1914, when the first concrete pavements of the present-day type were constructed.

There are now 360 miles of standard concrete pavements in the state highway system, all constructed within the past five years.

Commencing in 1909, and continuing to date, the State Highway Department has constructed a limited amount of brick pavement each year. There are now 350 miles of this pavement in the state system.

The state system contains about 122 miles of asphalt macadam (mixed method) pavements of various specifications, laid both on macadam and concrete base, which have been constructed over a period of ten years. Less than ½ mile has been reconstructed or given a general resurfacing.

In order to determine the relative cost of maintaining the various types of pavement, the State Highway Commission in the year 1915, decided to segregate the expenditures for maintenance and repair, charging to the various types of pavements all expenditures obligated to the roads of such types, and in the annual report for the year 1917 is found a tabulated statement of the average cost per mile, combined for the years 1915, 1916 and 1917, for the types having a material mileage in the state system.

Resurfacing Costs Omitted

This table should be qualified by a statement giving the average age of the pavements, as the relative cost of maintenance bears some considerable relation to the average age of the pavements maintained.

The ages of the pavements in the New York system in 1917 ranged about as follows: Water-bound macadam, 1 to 18 years; asphalt macadam, penetration method, 1 to 8 years; concrete pavement, 1 to 4 years; brick pavement, 1 to 8 years.

The maintenance cost data published by the New York Commission does not include resurfacing costs of brick and concrete pavements—as such work—as these pavements are not yet old enough to require resurfacing.

As the old macadam type of pavements shown in the table carries the resulting resurfacing charge, it will be necessary to eliminate this expense or to add an estimated charge for resurfacing of the concrete and brick pavements, and the first method would appear more consistent.

By reference to the annual reports and the latest bulletins, it is determined that during the years 1915-1916-1917, some 635 miles of resurfacing was performed, and that the average cost of the new top course, generally of asphalt macadam, was $6,260 per mile.

Five hundred and five miles, or 21%, of the water-bound macadam was resurfaced, representing an average charge of $437 per mile per year when distributed over the average number of miles of this type maintained; 57 miles, or 2%, of the asphalt macadam, penetration method, was resurfaced in this period of three years, the cost of which, distributed over the entire mileage of the type, represents an annual charge of $45 per mile. The records of the bulletin indicate that of the 80 miles of this type constructed in 1909, only 7.2 miles, or 9%, have been resurfaced in a period of nine years, or 1% per year.

Thirty miles of gravel and 43 miles of second-class concrete were also given a new asphalt macadam top course during this period, but as the types are obsolete they will not be considered in the table of comparative costs.

Complete Data Not Available

In the accompanying table an effort is made to illustrate the economic features pertaining to the selection of a pavement suited to the average highway having average traffic conditions. The cost of improvement is based on estimates prepared and proposals received by the New York State Commission and the fixed charge of interest is computed at 4% (sinking fund charges being omitted).

Type.	Average cost of improvement.	Interest on first cost at 4%.	Average cost of maintenance.	Total cost per mile per year, exclusive of renewal.
Asphalt macadam (penetration method)	$22,000	$ 880	$419	$1,299
Water-bound macadam	20,000	800	539	1,339
Concrete	35,000	1,400	124	1,524
Brick	50,000	2,000	196	2,196

The cost of upkeep and maintenance is taken from the published data in the report of the New York Commission for the year 1917, which has been amended by subtracting the cost of resurfacing of the macadam types as enumerated above in order that a consistent comparison may be made of maintenance costs only.

Complete data are not available with which costs of ultimate renewals by resurfacing can be determined.

While the periods between resurfacing of the more costly types are of longer duration than are those of the macadam types, the cost of such resurfacing is more expensive.

This table appears to demonstrate conclusively that the majority of the mileage should be constructed of the two macadam types.

The New York statistics are not sufficiently complete to determine what is the character and amount of traffic which will require the more expensive types.

Complete statistics should be collected; a traffic census should be taken frequently, and interest, sinking fund, resurfacing, renewal and maintenance cost per ton-mile ascertained, also the annual tonnage per foot width of road metal.

Wider Roads and Control

The demand for wider roads and more rigid control of traffic is even more pressing than of more durable types.

Until more detailed reports and statistics are available it will not be possible to estimate accurately probable traffic increase or to select in doubtful cases the most economical types of highway construction.

It is certain that the most heavily travelled highways should be wider, and that increase of width will add greatly to the life of all types of pavement.

At present 10% of the New York State improved highways are of brick or concrete construction—90% of bituminous and macadam types.

A careful study of New York State statistics and highways would indicate that there should be in the state aid system a gradual increase in the percentage of brick and concrete, with a corresponding decrease in percentage but not in mileage of other types, but it is unlikely that for many years the proportion of the more expensive types should exceed 20%, and at least 80%, or four-fifths, of the mileage will be of the various bituminous macadam types.

EFFECT OF VIBRATION, JIGGING AND PRESSURE ON FRESH CONCRETE*

By Duff A. Abrams
Professor in Charge, Structural Materials Research Laboratory, Lewis Institute, Chicago

EXPERIMENTAL study of the effect of vibration and pressure on fresh concrete on its strength and other properties is of interest in view of the frequent use of such devices as hand-hammering of forms, or air-hammering, jigging or vibration as an aid in placing concrete. Such methods are particularly applicable to the construction of reinforced-concrete ships and houses, where thin sections and a multiplicity of reinforcing members are of common occurrence. Jigging or vibrating machines are frequently used in concrete products plants. The effect of pressure on fresh concrete is of interest in certain problems of concrete design.

Little attention has heretofore been given to the experimental study of the effects produced by vibration and jigging fresh concrete. A few tests were made in a study of the effect of pressure on fresh cement paste in a confined space by James E. Howard, at Watertown Arsenal. The effect of pressure on the compressive strength and bond was studied by the writer at the University of Illinois in 1913. Since the tests now reported were completed, Prof. F. P. McKibben has published a report on compression tests of concrete columns which set under pressure.

The tests covered by this report were made as a part of the experimental studies of concrete and concrete materials being carried out through the co-operation of Lewis Institute and the Portland Cement Association, and include the following topics:—

1. Different methods of hand-molding of test cylinders.
   - (*a*) Puddling with ⅝-in. round steel bar (varying number of strokes).
   - (*b*) Tamping (tampers of different size).
   - (*c*) Tapping metal forms after puddling.
2. Effect of vibrating fresh concrete (small electric motor).
   - (*a*) Time of vibration varied up to 1 min.
3. Effect of jigging fresh concrete.
   - (*a*) Concrete of different mixes (1: 7 to 1: 3).
   - (*b*) Concrete of different consistencies (0.70 to 1.25).
   - (*c*) Using aggregate of different grading (fineness modulus 4.00 to 6.50).
   - (*d*) Using aggregate of different sizes (0-28 sand to 0-1½-in. concrete aggregate).
   - (*e*) Using coarse aggregate of different shape (pebbles and crushed stone).
   - (*f*) Effect of rate of jigging (0 to 150 r.p.m.).
   - (*g*) Effect of height of drop (0 to 0.50 in.).
   - (*h*) Effect of length of time jigged (up to 3 mins.).
   - (*i*) Effect of age of concrete before jigging (up to 6 hrs.).
   - (*j*) Jigged with 30-lbs. weight on top of fresh concrete.
   - (*k*) Hand puddling on jigging machine while in operation.
4. Effect of pressure on fresh concrete.
   - (*a*) Using different pressure (0 to 500 lbs. per sq. in.).
   - (*b*) Effect of duration of pressure (15 mins. to 16 hrs.).
   - (*c*) Effect of removal of water by pressure.

This series included 900 compression tests of 6 by 12-in. concrete cylinders at the age of 28 days. All specimens were made from the same materials at the same time, consequently direct comparisons may be made between any two sets of tests.

*Excerpts from paper presented to the American Concrete Institute.

The tests gave conclusive results on many phases of the effect of vibration, jigging and pressure. In some instances the effect is entirely different from what accepted opinion would suggest. Following is a brief summary of the tests:—

Puddling and Tamping

1. Varying the number of strokes from 12 to 50 on each 4-in. layer in the standard method of hand-puddling with a ⅝-in. bar had little influence on the compressive strength of ordinary plastic concrete.

2. In general, the tamping methods used gave lower strengths than hand-puddling.

3. A tamper of large diameter for a given weight was less effective than one of small diameter.

4. Increasing the thickness of the layer from 4 to 6 ins. caused a falling off in strength of about 12% for tamped concrete.

5. Tamping or puddling the first 4-in. layer only caused a falling off in strength of 10 to 13%.

6. Striking the metal form with a steel bar after the completion of moulding by standard method had no effect on the strength of concrete.

7. The "standard" method of hand-puddling, using 25 strokes with a ⅝-in. steel bar for each 4-in. layer of concrete in a 6 by 12-in. cylinder is recommended for laboratory tests of concrete.

Vibration with Electric Hammer

8. Vibration of the specimen after moulding by means of an electric hammer running at 1,000 r.p.m. had little influence on the strength of the puddled concrete up to a period of about 30 seconds. If continued, there was a steady falling off in strength; after 45 to 60 seconds the strength was only 90% of that produced by the standard method of puddling.

9. In general, jigging in any manner with the apparatus used reduced the compressive strength of the concrete, regardless of the height of drop, rate or duration of treatment. Exceptions were found in the dry mixes and those made of aggregates of the smaller sizes.

10. There was little difference in the effect of jigging due to the quantity of cement used.

11. In the very dry mixes the strength, due to jigging for 20 seconds, was increased about 25%.

12. The wetter mixes (relative consistency, 1.10 to 1.25) were reduced in strength 3 to 6% by jigging.

13. Pebbles and crushed limestone as coarse aggregate gave essentially the same results in the jigging tests.

14. The concretes for finer aggregates showed a material increase in strength with jigging in both 1: 5 and 1: 3 mixes.

15. For aggregate coarser than about ⅜ in., jigging reduced the strength from 3 to 10%.

16. The grading of the aggregates (for a given maximum size) had little influence on the effect of jigging.

17. The greater the drop, the greater the reduction in strength for 1: 5 concrete. For a drop of ½ in. the strength was reduced 12%.

18. The faster the rate of jigging, the lower the strength of 1: 5 concrete. Using 1½-in. aggregate at 150 r.p.m., the strength was reduced about 13%.

19. The strength of 1: 5 concrete fell off rapidly with the duration of jigging. After 2 to 3 minutes' jigging the strength was reduced about 20% as compared with standard method of hand-puddling.

20. Allowing the concrete to stand for a period of time before jigging increased the strength to a slight extent. The maximum increase was found at 2 to 4 hrs.

21. The application of a pressure of 1 lb. per sq. in. during the jigging process (equivalent to a head of 1 ft. of fresh concrete) gave the same strength as standard hand-puddling.

22. Moulding the cylinders by the standard method on the jigging table while it was in motion gave the same strength as standard hand-puddling without jigging.

FORESTS OF BRITISH COLUMBIA

At no time in the history of Canada has an accurate knowledge of our natural resources been of more vital importance than at present. In view of the keen commercial competition that will surely accompany "reconstruction," and because of the much larger national debt which Canada must now carry, all the efforts of this country must be devoted to the intelligent utilization and conservation of our natural resources.

To this end, accurate knowledge of the extent and character of our resources is of the greatest possible value. Very timely, therefore, is the splendid report on the forests of British Columbia which has just been published by the Commission of Conservation, Ottawa. This report has been prepared by H. N. Whitford and Roland D. Craig under the direction of Clyde Leavitt, chief forester of the Commission. It comprises 390 pages of type matter and tables, 6¾ by 9¾ ins., in addition to a 19-page index, numerous inserts bearing half-tone illustrations, and several folded maps.

Part 1 covers geographical, physiographic, climatic and soil relations; land tenure; forest administration on provincial and Dominion lands; forest policy and exploitation; trees and insect injuries.

Part 2 describes the forest resources of the interior of British Columbia, of the coastal belt of the province, and of the province as a whole. Appendices are the timber sale contract form, volume tables compiled by the British Columbia Forest Branch, and a condensed British Columbia log scale.

As the authors point out in the introduction to their report, it is poor economy to attempt to develop any industry for which the basic materials are not available in sufficient quantities to ensure successful operation. In order that industry may be intelligently applied, a knowledge of the natural resources upon which it depends is fundamental. Through lack of knowledge, the forest resources of Canada have often been described as "illimitable." While the forest resources of British Columbia are vast, constituting one of Canada's most important resources, they are not illimitable, and the report just issued by the Commission of Conservation will aid greatly in their proper conservation. Incidentally, it may be pointed out that the definition of the word "conservation" that has been accepted by the Commission, includes efficient utilization.

Letter to the Editor

METRIC SYSTEM REVISED

Sir,—Referring to my letter re international measures, published in last week's issue of your paper, would you be kind enough to add the following tables:—

PROPOSED TABLES

Length

1,000 mils = 1 inch (131% present inch).
10 inches = 1 metric foot.
3 metric feet = 1 meter (exact).
100 metric feet = 1 chain.
4,800 metric feet = 1 mile (99.4% present mile).

Area

100 square inches = 1 square foot.
9 square feet = 1 square meter (exact).
36,300 square feet = 1 acre (99.7% present acre).

Content

1 cubic inch = 1 ounce.
100 ounces = 1 gallon (82% Imp. and 102% American gal.).
1,000 ounces = 10 gallons = 1 bushel = 1 cubic foot.
27 cubic feet = 1 cubic meter.

Weight

1 cubic inch = 1 ounce.
12 ounces = 1 lb. (98% present pound).
2,000 lbs. = 1 ton.

C. R. COUTLEE,
Department of Public Works.

Ottawa, Ont., July 28th, 1919.

CONSTRUCTION OF WATER-BOUND MACADAM ROADS

(Continued from page 178)

macadam surfaces are damaged by the melting of the snows. It is impossible to hasten drainage in this territory, where the land has practically no slope.

It has been suggested that in the most exposed places, the surface should be rebuilt with a bituminous binder. Where the water crosses the road with a strong current, a local concrete pavement is usually recommended. There are, however, a number of places where the erosion is purely accidental, and in these places it is sufficient to repair the macadam surface in the ordinary way.

We must carefully distinguish between disintergration of macadam and wear. The wear is natural and unavoidable, otherwise we would have roads with permanent surfaces, which is an impossibility. It is therefore not always wise to undertake repairs at the first sign of wear on macadam. At other times, on the other hand, wear can be retarded and life lengthened by the application of certain materials such as bituminous binders, asphaltic oils or even a thin layer of fine, hard gravel. This last proposition especially provides an economical cure for rough surfaces.

Many things can be said regarding the construction and up-keep of water-bound macadam, and an article entering into all the details would involve a regular course in construction work. The writer has treated the subject briefly and only from the point of view of the Province of Quebec.

PERSONALS

FRANK BARBER, consulting engineer, Toronto, whose design for the $300,000 Hunter Street bridge, Peterborough, Ont., which will be the longest concrete arch bridge in Canada, was formally accepted by the city of Peterborough last week by the mayor's signing the constract for its construction, was born December 27th, 1875, at Milton, Ont., and was educated at the Dunnville high school, Mount Allison University and the University of Toronto, where he graduated in 1906 in the civil engineering course, specializing in mathematics. After graduation Mr. Barber entered the office of the late James MacDougall, who was then engineer of York County, Ont., and later became Mr. MacDougall's chief assistant. Upon Mr. MacDougall's death in 1908, Mr. Barber entered private practice and was also appointed York County engineer. Mr. Barber was in partnership with C. R. Young, who is now an associate professor at the University of Toronto, under the firm name of Barber & Young, until 1911, when Mr. Young joined the staff of the University as a lecturer. From 1908 until the outbreak of war, Mr. Barber and his staff designed and planned an average of about thirty bridges a year in various parts of Canada, including the longest concrete arches and some of the longest steel highway bridges in Ontario, also including the first open spandrel arches in Canada and fifteen out of the first twenty concrete truss bridges in the Dominion. At the outbreak of war, when bridge work partially stopped, Mr. Barber became managing-director of the Thor Iron Works, Ltd., Toronto. This plant was soon converted into a shipbuilding yard, and in 1917 launched its first ocean-going steel freighter. Under Mr. Barber's management the business is said to have increased from $200,000 to over $1,000,000 a year. In October, 1917, he sold his interests in the firm to New York shipbuilders who reorganized the business as the Dominion Shipbuilding Co., and Mr. Barber decided once more to devote his entire time to consulting work. He is at present corporation engineer or consulting bridge engineer for the counties of York, Simcoe and Haldimand, and the townships of York, Vaughan, Etobicoke, King and various other townships and towns. During the past two years he has acted in association with R. O. Wynne-Roberts for various water works, sewerage and other municipal improvements, including water works extensions costing about $1,000,000 for York Township. The firm is now reporting on a sewerage scheme for York Township which will also cost about $1,000,000.

WILLIS CHIPMAN, of the firm of Chipman & Power, consulting engineers, Toronto, is in British Columbia (Vancouver Island) on an engineering mission for the Dominion Government.

CHARLES R. MURDOCK, who for the past nine years has been on the staff of Chipman & Power, consulting engineers, Toronto, has resigned to accept an appointment as town engineer of Dundas, Ont. Mr. Murdock graduated in 1906 at the University of Toronto, with the degree of B.A.Sc. He was formerly resident engineer for Chipman & Power at that firm's Winnipeg office.

NORMAN MALTMAN, formerly purchasing agent of the Russell Motor Car Co., Toronto, has joined the staff of A. R. Roberts, Toronto, who recently severed his connection with the firm of Burns & Roberts, Ltd., and opened a new office as manufacturers' agent and dealer in new and used machinery.

OBITUARY

A. C. MACKENZIE, who was for many years an outstanding figure in the construction world of Western Canada, died suddenly last Friday at the power plant which is under construction on the Winnipeg River. Mr. MacKenzie was 56 years of age. He was president of the Northern Construction Co., who are the contractors for the Winnipeg River power plant. For over 20 years he was one of the best known railway contractors in Western Canada, having been actively identified with the C.N.R. interests. Interment took place last Monday at Beaverton, Ont.

EFFECT OF VIBRATION, JIGGING AND PRESSURE ON FRESH CONCRETE

(Continued from page 192)

23. The compressive strength of concrete was increased by pressure applied immediately after moulding. For pressure of 200 to 500 lbs. per sq. in. the increase was 20 to 35%.

24. The duration of pressure as between 15 mins. and 16 hrs. produced no difference in strength.

25. There was a steady reduction in the water-ratio of the concrete with the application of pressure.

26. The application of pressure increased the strength of concrete in accordance with the quantity of mixing water expelled.

27. The tests of concrete subjected to pressure showed the usual relation between compressive strength and water-ratio. The strength is increased *because the water is expelled.* In other words, pressure produces a drier concrete, and, consequently, gives higher strength. This makes it clear why the duration of pressure has no influence on the result.

The indications of the vibrations and jigging tests should not be misinterpreted. The tests show that *after the concrete is properly placed* these methods of treatment do no good, and may be harmful if too severe or too long continued. However, there can be no doubt of the value of such methods *for getting concrete into place* in intricate forms and around reinforcing bars. The tests are of value in showing that this is the only desirable function of such treatments. One series of tests shows the ill effects of lack of compactness in the concrete, the strength being reduced 13% due to failure to tamp or puddle the top 9 ins. of the cylinder. It is impracticable to duplicate in a compression test piece the performance of air hammers and other similar methods of vibrating when used on reinforced concrete work.

The tests show that with jigging high strength may be secured with drier mixes than would be feasible otherwise. It is a matter of common experience that concrete of drier consistency (and, consequently, higher strength) can be placed by means of jigging or vibration than would be possible by the usual methods.

There are already thirty-two surrendered German aeroplanes assembled at Toronto, and all will be displayed or flown at the Canadian National Exhibition, August 23rd to September 6th. Canada owns nearly 100 German or allied planes, and they will eventually become part of the official museum display or be distributed among the various cities by the Dominion government.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

BRIDGES, ROADS AND STREETS

Andover, Victoria County, N.B.—The provincial department of public works is calling for tenders for construction of roadway embankments.

Banff, Alta.—The road from Banff, eastward to the park limits, will be improved. Estimated cost, $14,000. Superintendent Wardle, Banff Park.

Belleville, Ont.—Recent by-laws passed by the city council provide for the construction of granolithic sidewalks, $16,635.06 and pavements, $17,756.50. J. Wilfred Holmes, city clerk.

Belleville, Ont.—The city council contemplates construction of asphaltic concrete pavements on Pinnacle St., cost, $25,963.40; Coleman St., $19,182.32; Ann St., $12,228.20; Campbell St., $3,633.03; George St., $26,811.70; Burnham St., $13,972.40, and William St., $11,778.90. J. W. Holmes, city clerk.

Birtle, Man.—Contract has been awarded for construction of three bridges to La Cour and Schisler, Winnipeg. Contract price, $3,100. W. B. Chapman.

Bishop's Crossing, Que.—Tenders will be received until noon, August 2nd, for construction of part of the Beauce Junction-Sherbrooke road, in Dudswell, from the town line of Weedon to the town line of Marbleton. H. Cunningham, secretary-treasurer.

Brantford, Ont.—Plans are being prepared by the city engineer to pave West St., connecting with the county road pavement.

Calgary, Alta.—The Dominion and British Columbia governments have agreed to complete the construction of the Calgary-Windermere section of the highway. Estimated cost to complete, $2,500,000. J. W. Davidson, Calgary.

Cloverdale, B.C.—The Surrey council has decided to repair roads. Estimated cost, $1,000.

Edmonton, Alta.—The department of works will recommend paving the north side of Norwood Blvd., from 95th to 97th St. City Engineer Haddow.

Glenwood, Man.—The municipal council will proceed with their program of road improvement, under the terms of federal and provincial grants.

Langier, N.S.—A meeting of ratepayers from the eastern district of Halifax county will urge the provincial government to reconstruct all the main roads. G. Mason, secretary.

Lincoln, N.B.—The contract for the Harris bridge in the parishes of Lincoln and Burton, Sunbury county, has been awarded to Frank L. Boone, South Devon. Contract price, $51,000.

Lindsay, Ont.—Tenders will be received until 2 p.m., August 5th, by J. R. McNeillie, county clerk, for construction of a 40 ft. concrete arch truss bridge at concession 4, lot 16, Mariposa township; a 16 ft. Flynn concrete bridge, at concession 10, lot 11, Emily; a 16 ft. West cross creek bridge, Township of Ops. Engineers, Bowman and Connor, Toronto.

L'Orignal, Ont.—Contract has been awarded to Grant Bros., Ottawa, for construction of 5 miles of the Montreal-Ottawa Rd., east of Orleans. This will be a bituminous road, 16 ft. in width and is to be completed this fall. Contract price, bituminous binder, 34 cents per sq. yd.; loose metal per cu. yd., $3.35. Victor Belanger, engineer.

McGillivray Township, Ont.—Tenders will be received until 1 p.m., August 2nd, by the county council for excavating hill and widening grade on county road. Charles Talbot, county engineer, county building, London, Ont.

Moncton, N.B.—The city council has awarded the contract to the Warren Bituminous Paving Co., Ltd., for paving the following streets: Highfield St., from St. George to John St.; High St., from No. 4 fire station to John St.; King and Union Streets, from the city hospital to Botsford St.; and John St., from High to Highfield Sts. The contract also calls for the laying of bitulithic topping on Highfield and Botsford Sts. City engineer, Edington.

Montreal, Que.—Luna Park, Ltd., will construct additions to bridge at Back River. Estimated cost, $15,000. Architect, L. Lemieux, 364 University St.

Montreal, Que.—The department of works will proceed with paving St. Lawrence St. The concrete base has been laid over two years and will be repaired. Estimated cost, $35,000. Chief engineer, Doucet.

Moorefield, Ont.—Tenders will be received until 11 a.m., August 4th, by the township of Maryboro, for construction of a 55 ft. steel bridge at lot 6, concession 15. W. W. Scott, town clerk. Engineers, Bowman and Connor, Toronto.

Moose Jaw, Sask.—By-law will be submitted to the ratepayers on August 7th, authorizing debentures for repairs to roadway of Fourth Ave. s.w. bridge. Estimated cost, $16,000. R. P. Riddell, city clerk.

Murrayville, B.C.—Langley council will repair and construct roads. Estimated cost, $2,110.

Oakville, Ont.—The contract was awarded to George McLaren, town foreman, for building tarvia roads on Navy, Dunn, Reynolds, Howard and Douglas Streets.

Orangeville, Ont.—Tenders will be received until 2 p.m., August 11th, for construction of the following reinforced concrete culverts, bridges and abutments: In the county of Dufferin, bridges—7 of 10 ft. span, 2 of 12 ft., 1 of 14 ft., 1 of 16 ft., 1 of 20 ft., 1 of 22 ft., 3 of 24 ft.; culverts—1 of 4 ft. span, 4 of 6 ft., 1 of 8 ft. In the township of Albion—1 pair of abutments for a 55-ft. steel truss, 1 pair of abutments for a 48-ft. steel truss. In the township of Toronto Gore—1 bridge, 32 ft. span. In the township of Toronto—1 bridge of 12 ft. span. Wheelock and Christie, engineers, Orangeville, Ont.

Owen Sound, Ont.—The board of works will send a deputation to Toronto to examine different classes of roads under construction before awarding contracts recently opened.

Park's Brook, N.B.—Contract has been awarded for the Park's Brook (Mouth) bridge, Northumberland county, to D. C. Burpee and Son, South Devon. Contract price, $9,000.

Peterboro, Ont.—The mayor formally signed the contract last week for the Hunter St. bridge, and the successful contractors, Russell, Townsend & Co., of Toronto, have two car loads of plant now on the job, and Mr. Christie, assistant engineer in the office of Frank Barber, consulting engineer, Toronto, is here laying out the work.

Point Edward, Ont.—Tenders will be received until August 1st by the board of works for construction of concrete sidewalks on Alfred and Monk St. Wm. H. Barrett, chairman.

Saskatoon, Sask.—Tenders will be received until about August 12th by the highways department of the provincial government for construction of three new steel and concrete bridges, to be located at Tisdale, Benito and Wascana Creek.

South Vancouver, B.C.—Tenders are called for hard-surfacing of Fraser Ave., from 59th St. to Marine Drive. Municipal council.

Stamford Township, Ont.—Sealed tenders will be received until 8 a.m., August 4th, by the township council for construction of concrete walks, section No. 9. Township

clerk, C. F. Monroe. Engineer, J. C. Gardner, Niagara Falls, Ont.

St. David de L'Auberiviere, Que.—Tenders will be received by the Levis Road Commission until August 4th for a cement pavement. Secretary, Arthur Pigeon, government building, Quebec, Que.

St. Telesphore, Que.—Tenders will be received until August 4th by the Levis Road Commission for a steel bridge over the Scie River. Secretary, Arthur Pigeon, government building, Quebec, Que.

Toronto, Ont.—Tenders will be received until noon, August 11th, by the department of works, city hall, for construction of the following pavements, curbs and sidewalks: Pavements, asphalt—Cawthra Ave., from Junction Rd. to 264 ft. south; Elm St., from Yonge St. to Chestnut St. (except the intersections of Teraulay and Elizabeth St.); Front St., from York to Simcoe St.; Grosvenor St., from Yonge to Queen's Park (except intersection of Surrey Pl.); Heintzman Ave., from Dundas St. to north end; Monarch Rd., from Weston Rd. westerly and southerly to south end; Pendrith St., from Christie to 200 ft. east of Shaw St.; Silverthorne Ave., from St. Clair to Rowntree Ave. Bitulithic—Exeter Ave., from Laughton Ave. to east end. Brick block—Silver Birch Ave., from Queen St. to 1,100 ft. north. Grading—Drayton Ave., from Danforth Ave. to 220 ft. south of Hanson St. Concrete curbs—Annette St., S.S., from Indian Gr. to Keele St.; Grosvenor St., both sides, from Surrey Pl. to Queen's Pk.; Prescott Ave., E.S., from St. Clair Ave. to East Ave.; Silverthorne Ave., E.S., from 206 ft. south of Howick Ave. to 152 ft. farther south.; Silverthorne Ave., W.S., from 239 ft. south of Howick Ave. to 86 ft. farther south; Silverthorne Ave., W.S., from Turnberry Ave. to Rowntree Ave. Concrete sidewalks—Drayton Ave., both sides, from 220 ft. south of Hanson St. to Danforth Ave.; Jones Ave., W.S., from 153 ft. south of Mallon to 310 ft. farther south; King St. West, N.S., in front of Nos. 22, 24, 26 and 28; Moutray St., N.S., from Sheridan to Brock Ave.; Neville Park Blvd., E.S., from Queen to west limit of lot No. 50. T. L. Church, chairman, board of control.

Toronto, Ont.—Tenders will be received until 12 o'clock noon, August 18th, by the department of public highways, Toronto, for the necessary grading and bituminous road construction on the following sections of the provincial highway: Section No. 1, from the easterly limit of the city of London to the westerly limit of the town of Ingersoll, 15.93 mls. Section No. 2, from the easterly limit of the city of Brantford to the village of Ancaster, 15.62 mls. Section No. 3, from the easterly limit of the village of Beamsville easterly a distance of 3.25 mls. Section No. 4, from the easterly limit of the town of Trenton to the westerly limit of the city of Belleville, 9.13 mls. Section No. 5, from the westerly limit of the city of Kingston to the westerly limit of the township of Kingston, 7.72 mls. Section No. 6, from the easterly limit of the city of Brockville to the westerly limit of the town of Prescott, 10.46 mls. (Official advertisement in this issue.)

York Township, Ont.—Tenders will be received until 10 a.m., August 5th, for construction of concrete sidewalks on Westwood and Hillbrow Ave. (Official advertisement in this issue.) Frank Barber, township engineer, 40 Jarvis St., Toronto.

WATER, SEWAGE AND REFUSE

Belleville, Ont.—Contracts have been awarded by the city council to J. C. Wilde for construction of sewers on Yeomans, Cedar, Boswell and Isabel Sts. Contract price, $16,043.45. J. W. Evans, city engineer.

Belleville, Ont.—Recent by-laws passed by the municipal council provides for the construction of sewers. Estimated cost, $32,871.06. J. Wilfred Holmes, city clerk.

Burlington, Ont.—Contract has been awarded for the construction of sewers to D. O. Johnson, of Johnson Bros., Brantford, Ont. Mr. Johnson will supply the required vitrified pipe. Contract price, $18,200. Consulting engineers, Chipman & Power, Toronto.

Burnaby, B.C.—Westminster council has decided to proceed with the construction of the Glenbrook sewer.

Dundas, Ont.—Contracts for sewer construction and sewage disposal plant have been awarded by the council as follows: For sewers, to F. F. Fry, Toronto, $126,757; for disposal works, pump-house, etc., F. F. Fry, Toronto, $49,676.60; ejectors and piping, John Bertram & Sons Co., Dundas, $1,500; air compressors, motors and air tank, Smart-Turner Co., Hamilton, $2,659; cast-iron pipe and specials. Gartshore Pipe and Foundry Co., Hamilton, $2,445.40; sprinkler equipment, valves, etc., for disposal works, Francis Hankin Co., Montreal, $6,888.30; sewer pipe, Hamilton and Toronto Sewer Pipe Co., Ltd., Hamilton, $23,866.84; segment block (30-in.), Toronto Pottery Co., Toronto, $10,175. Total amount of contracts, approximately $225,000. The system will be built from plans and specifications prepared before the war by the former firm of Murray & Lowes, consulting engineers, Toronto, who estimated the cost of the system at that time at $150,000. There was considerable competition for the sewer contracts, the following tenders having been received in addition to Mr. Fry's: R. A. C. Smith, Hamilton, $128,000; J. J. Armstrong & Sons, Hamilton, $130,000; Canadian Engineering and Contracting Co., Hamilton, $152,000; Kerr & Clement, Orillia, Ont., $155,000; Connolly-Agnew Construction Co., Toronto, $228,000. The competition for the disposal works was practically confined to Mr. Fry and the Connolly-Agnew Construction Co., who bid $50,325.05. The sewage disposal plant will be concrete and brick. Work will be started at once, and Mr. Fry expects to finish the disposal works this year and the sewers by the end of next summer.

London, Ont.—Tenders will be received until noon, August 4th, for excavating Oxbow Creek drain. M. Grant, township clerk, London, Ont. F. W. Farncomb, engineer, London.

Moose Jaw, Sask.—By-law will be submitted to the ratepayers on August 7th authorizing debentures for extensions to waterworks at Britannia Park. Estimated cost, $40,000. R. P. Riddell, city clerk.

New Toronto, Ont.—The plans for new water mains have been approved by the provincial board of health. Active construction of the system will now be carried out on 16th, 10th and 4th Sts. Estimated cost, $18,000.

North Bay, Ont.—Sealed tenders will be received until 12 o'clock noon, August 1st, by the fire, water and light commission, for the construction of the following water mains: Worthington St., from John to Metcalf; McIntyre St., from Regina St., 400 ft. westerly; Hardy St., from John St. easterly; Second Ave., from Wyld to Ferguson St.; Fourth St., from Cassells St., 400 ft. southerly; McIntyre St., from a point midway between Ferguson and Fraser Sts., 100 ft. easterly. E. C. Rheaume, chairman.

Owen Sound, Ont.—By-law was introduced providing for sewers to be constructed as local improvements on 2nd Ave. West and on 10th St. West. C. H. Thompson.

Peterboro', Ont.—The city council contemplate construction of a sewage disposal plant. This project was under consideration in 1914, but was postponed. The townships of Otonabee and the two Monaghans have threatened an injunction to restrain the city from dumping raw sewage into the river. E. A. Peck, solicitor for townships.

Toronto, Ont.—The department of works will lay new 24 in. diam. cast-iron water mains along Withrow, Pape and other streets to relieve the water scarcity in North Riverdale district.

Walkerville, Ont.—Tenders will be received until August 12th by the Essex Border Utilities Commission for the construction of a sewerage pumping station. G. M. McGregor, chairman; W. M. Baxter, secretary, Room 14, Victoria Block, Windsor, Ont.

Waterloo Township, Ont.—Contract has been awarded to Crawley and Gaunt, Arthur, Ont., for construction of municipal drain No. 2. Contract price, 50 cents per cu. yd. P. A. Snider, Breslau, Ont.

Welland, Ont.—Contract has been awarded to Somerville and Dilworth for sewer on Fisher St., contract price, $780.50. Rejected tender, Martin Miller, $1,050. City engineer, Chas. L. Coulson.

Windsor, Ont.—Tenders for constructing the Walkerville sewerage pumping station, in connection with the intercepting sewer now being constructed through the Essex County border cities, will be received by the Essex Border Utilities Commission, Victoria Block, Windsor, until August 12th. Five dollars deposit required on plans and specifications.

Woodstock, Ont.—Dr. Andrew McKay, medical officer of health, has reported pollution in the domestic water supply taken from Cedar creek, as a result of the inflow of city sewage, and has requested that the city council take immediate action to remedy conditions.

LIGHT, HEAT AND POWER

Chatham, Ont.—The Chatham, Wallaceburg and Lake Erie Ry. will be operated under hydro power within six weeks. Two 250 k.w. rotaries will be installed in Chatham, one at Wallaceburg and one at Cedar Springs. Mr. Curte, manager.

Vancouver, B.C.—The report of the Commission of Conservation places the total estimated 24 hour horse-power available from the water powers of British Columbia to be 3,000,000.

Winnipeg, Man.—The Winnipeg River Power Co., will develop power from the Bonnet Falls, 75 miles north-east of Winnipeg. This plant will have an ultimate capacity of 168,000 h.p. in six units, each of 28,000 h.p.

RAILWAYS

Cobourg, Ont.—The Hydro Commission contemplates taking over the Ontario Eastern Electric Railway and extending same to Kingston.

Copper Mountain, B.C.—Construction has again commenced on the branch railroad running to Copper Mountain from the Kettle Valley Ry. Contractors, Tierney Bros.

Halifax, N.S.—The Canadian National Railways has awarded contracts for double-tracking the main line from Halifax to Moncton, N.S.; one section in New Brunswick and one section in Quebec. Work will start immediately.

The Pas, Man.—The Canadian National Railways have absorbed the Hudson Bay Railway. Ten miles of construction will probably be completed this year to connect with the Nelson River.

Toronto, Ont.—Construction of the Toronto-Niagara hydro radial line will probably commence soon. Engineers are checking up on the surveys and the right-of-way will then be acquired. Sir Adam Beck, chairman, Hydro-Electric Power Commission.

FACTORIES AND LARGE BUILDINGS

Brantford, Ont.—An electric tin smelting plant will be established on property adjoining that of the Verity Plow Co.

Brantford, Ont.—The Cockshutt Plow Co., will make extensive additions to their plant. Estimated cost, $100,000.

Brantford, Ont.—The Brantford Roofing Co. has commenced construction of an extension to the boiler plant. Estimated cost, $5,000.

Brantford, Ont.—The Brantford Scale Co. has awarded a contract for erection of an addition to their present plant. Plans are being prepared to double the capacity of the plant by further additions.

Brantford, Ont.—The Cockshutt Plough Co. has commenced construction of an additional storage warehouse, estimated cost, $9,500, and an experimental building, estimated cost, $15,000.

Bridgeville, N.S.—Tenders will be received by the school board until August 30th, for construction of an addition to the school at Bridgeville, county of Pictou. P. L. Lithgow, secretary, R.R. No. 1, Eureka, N.S.

Calgary, Alta.—R. F. Baxter, 1111 Tenth Ave., will erect an addition to his warehouse. Estimated cost, $3,000.

Calgary, Alta.—The contract for the new post office to be erected here will be awarded during August. Major L. Redman, M.P.

Creston, B.C.—A new high school building will be erected in the school property. Chas. Moore, chairman.

Creston, B.C.—The ratepayers of the Creston school district have decided to erect a new school building. Estimated cost, $6,000.

East Toronto, Ont.—Four public schools or additions to present schools will be constructed during this summer, in the east end of the city.

East Toronto, Ont.—George and Moorehouse, architects for the Norway School on Kingston Rd. Estimated cost, $45,000. John Siddall, architect for a three-story addition to the Duke of Connaught School. Estimated cost, $45,000. Ellis and Ellis, architects for administrative section to be added to the North Leslie St. School. Estimated cost, $90,000. E. G. Bird, architect for three-story addition to Earl Grey School. Estimated cost, $50,000.

Edmonton, Alta.—Tenders will be received until 12 o'clock noon, August 7th, by the department of public works for construction of Principals' residences at the Agricultural schools, Vermilion, Claresholm and Olds. I. C. Charlesworth, deputy minister.

Edmonton, Alta.—The new telephone exchange, to have an ultimate capacity of 14,000 lines, will be constructed immediately, to be completed by January, 1920. J. Lowry, superintendent.

Edmonton, Alta.—The tenders for the Keith sanitarium as submitted were considered too high. Excavation work to the extent of $55,000 has already been done, and it is probable that the remainder of the construction and installation of mechanical equipment will be done by day labor, or on a percentage basis.

Fort Garry, Man.—The municipality will construct new houses under the provisions of the Federal Housing Act. Estimated cost, $100,000.

Fort William, Ont.—The Western Elevator Co. will erect a reinforced concrete building to be used for garage, lunch room, etc. Estimated cost, $20,000.

Galt, Ont.—The city council has decided to build a new grand stand in Dickson Park. Estimated cost, 15,000.

Glace Bay, N.S.—Contract has been awarded to Joseph McKinnon for construction of central school.

Guelph, Ont.—The Ontario Agricultural College will erect a memorial hall in honor of their soldier students. Estimated cost, $100,000.

Halifax, N.S.—Tenders will be received until noon, August 30th, by the board of the school commissioners, for construction of four new schools, complete with lighting and heating. S. J. Wilson, secretary.

Halifax, N.S.—The Salvation Army contemplate construction of a new maternity home to accommodate about 75 beds. Col. G. Miller, property secretary.

Hepworth, Ont.—A new glove factory will probably be located here. The motive power for the factory is to be natural gas.

Hull, Que.—Contract has been awarded by the department of agriculture to Doran and Devlin, Ottawa, for construction of a cattle barn at the research station, Hull, Que. contract price, $5,380.

Indian Head, Sask.—Tenders are called until August 12th by the department of public works, Ottawa, for construction of a brick office building for the forestry branch. Plans, etc., at resident architect's office, Winnipeg, and at the chief architect's office, Regina. R. C. Desrochers, secretary.

Kentville, N.S.—A combined hospital is being planned as soldiers' memorial for the surrounding counties. W. H. Chase, chairman of the memorial executive.

Kingston, Ont.—The United Hotel Co., Niagara Falls, N.Y., will prepare plans for new hotel. F. A. Dudley.

Kitchener, Ont.—The Canadian Consolidated Rubber Co., Ltd., Montreal, has decided to increase their plant in Kitchener. Estimated cost, $1,000,000.

Lindsay, Ont.—Contract for the new main hall at the fair grounds will not be awarded until September.

Markdale, Ont.—Tenders will be received until August 7th by J. E. Marsh for rebuilding of Markdale hotel.

Midland, Ont.—An addition to the hospital will probably be erected as a soldiers' memorial. J. McDowell, mayor.

Moncton, N.B.—Additional building permits include an I.C. Ry. freight shed, French academy, moving picture building and dwellings. Estimated cost, $900,000.

Moncton, N.B.—Contracts have been awarded by the Canadian National Railways for the following section houses; Picard, Que., Lapointe, Que., Bretagne, Que. and Lefebvre, Que., to A. J. Morin, of Garthby, Que. Near Grog Brook, N.B., and Sirois, N.B., to Hamilton and Collier, of Campbellton, N.B. Grog Brook, N.B., to Isreal Roy, Green Point, N.B. Chief engineer, C. B. Brown.

Montmartre, Sask.—Contract has been awarded by the Sisters of Forget to S. Pritchard, Moose Jaw, for construction of new convent. J. E. Fortin, architect, Gravelbourg. Estimated cost, $50,000.

Moose Jaw, Sask.—A by-law will be submitted to the ratepayers on August 7th, to authorize debentures for construction of a public comfort station. Estimated cost, $13,000. R. P. Riddell, city clerk.

New Westminster, B.C.—Contracts have been awarded by the executive of the R. A. and I. Society for construction of the hog and swine building to Archie Hogg. The poultry and sheep sheds were awarded to J. Hetherington.

New Westminster, B.C.—The school board will erect a four-room addition to the Herbert Spencer school and will soon call for tenders.

North Wiltshire, P.E.I.—Contracts have been awarded by the department of public works, Ottawa, for construction of medical officers' residence, $14,950, Vocational building, $30,476 and pump house, $2,180, to Henry J. Phillips, Charlottetown, P.E.I. R. C. Desrochers, secretary.

Oakville, Ont.—The town council has granted the school board $22,000 to construct a new school building.

Port Arthur, Ont.—The local housing committee have requested the city council to prepare a by-law covering debentures for construction of houses. Estimate of cost, $250,000. J. A. Miskimmins, vice-chairman.

Regina, Sask.—Sub-contracts have been let by Wilson and Wilson, general contractors for the heating and plumbing at the Eastern Annex school, to Potts and Smith; sheet metal work to Hastings and Willoughby, Regina.

Regina, Sask.—The new barracks for the Royal Northwest Mounted Police will be built this summer. Date of completion probably November 1st. Storey and Van Egmond, architects. A new chapel, three houses for officers and a row of three houses for the N.C.O.'s will probably be erected next year.

Saskatoon, Sask.—Contract for the new elevator for the Quaker Oats Co. has been awarded to the Leonard Construction Co. It is to be of reinforced concrete throughout, and construction will commence about August 1st.

St. John, N.B.—The Salvation Army has awarded contract for construction of a new wing to the Maternity Home. A similar hospital is planned for Halifax, N.S. Estimated cost of both hospitals, $750,000. Col. G. Miller, property secretary.

Strathroy, Ont.—Tenders will be received until August 8th by the Dominion Canners for construction of a process-room, boiler and engine-room, etc. Thomas Wooster, Aylmer, Ont.

Sudbury, Ont.—The separate school board contemplates construction of a new school. Estimated cost, $10,000. John Frawley, secretary.

Thorold, Ont.—The town council will proceed to construct houses under the provincial housing act. Estimated cost, $50,000.

Toronto, Ont.—The city architects department issued seven permits on July 21st for construction of houses. Total value, $39,600.

Toronto, Ont.—The Imperial Oil Co. have received permission from the city council to establish a free air service station and public lavatory at the corner of Bloor and Dundas Sts. Estimated cost, $20,000.

Toronto, Ont.—The Silverthorne branch of the G.W.V.A. are constructing a new club house. J. F. Ross, president.

Trenton, Ont.—J. B. White, government arbitrator will value 70 lots expropriated by the Trenton Housing Commission. Houses will be built on these lots under the terms of the provincial housing act. Estimated cost of houses, $200,000.

Truro, N.S.—Tenders will be received until August 8th for construction of the maritime home for girls. Separate tenders are asked for plumbing and heating. R. W. Ross, president, Halifax, N.S.

Vancouver, B.C.—A sub-committee of the Reconstruction league will endeavor to have the auditorium project completed and construction started. Members of committee, G. P. Hicks, G. H. Howker, J. Leyland and Frank Wrigley.

Vancouver, B.C.—A technical school will likely be established here. The site and $25,000 in equipment is available. Probable cost, $250,000. Mrs. Moody, chairman of committee.

Wadena, Sask.—Contract has been awarded to Ross and Co., Saskatoon, for construction of a new union hospital. Contract price, $25,500. Dr. M. M. Seymour, commissioner of public health for Saskatchewan. Architect, N. L. Thompson, Saskatoon.

Winnipeg, Man.—Gordon, Ironside and Fares will construct an addition to their present plant. Estimated cost, $10,000.

Windsor, Ont.—The city council contemplates construction of a new eight-room addition to the Dougall Ave. school. Estimated cost, $65,000. M. A. Dickinson, acting clerk.

Winnipeg, Man.—The Maple Leaf Milling Co. are remodelling some of their 50 elevators situated in the west.

Welland, Ont.—The city council will borrow $250,000 from the province under the federal and provincial housing scheme to construct workmen's houses.

Yarmouth, Ont.—A new memorial school will be built at Locke's and an addition added to the Height's school. Combined estimate of cost, $22,000. W. Hill, Yarmouth.

York Township, Ont.—Seventy-five applications for houses have been received by the housing committee. Contracts have been prepared for 13 houses, which will be erected at once.

MISCELLANEOUS

Andover, Victoria County, N.B.—The department of public works is calling for tenders for construction of the McKinnon concrete arch culvert.

Anse aux Gascons, Que.—Tenders will be received until 12 o'clock noon, August 14th, by the department of public works, Ottawa, for construction of wharf. Plans, etc., at the offices of the district engineers, Rimouski, Que.; Post Office building, Quebec; Shaughnessy building, Montreal; and at the post office, Gascons, Que. R. C. Desrochers, secretary.

Belleville, Ont.—A meeting of property owners will consider buying some 7,000 acres of land adjacent to the city of Belleville from the Grand Trunk Ry. They propose to convert this into a large industrial district, taking advantage of the provincial housing act. W. C. Mikel, K.C., Belleville, Ont.

Calgary, Alta.—Construction of the Taber district irrigation project will be commenced at once and completed during June, 1920. Estimated expenditure, $200,000. Acreage to be irrigated 17,500. T. A. Sundal, Taber, Alta.

Cargill, Ont.—The new organization, under the name of Cargill, Ltd., will operate the electric light and power plant,

No Damage at these Curves!

Entrance to Queen Victoria Park, Niagara Falls, Ont. Roadway surface treated in June 1918 with "Tarvia-B."

When swift and heavy automobiles sweep around the bend of an ordinary macadam road the tires slip sidewise—not enough to skid, to be sure, but enough to rub and rasp the brittle macadam until the stones loosen and the surface ravels.

No road is better than its curves.

The curves are always the first spots in a road that need repair.

With plain macadam construction the curves are a *constant source of trouble and expense.*

Not so with Tarvia-macadam: Note the excellent condition of the curves in the Tarvia roads pictured here.

Curves have no terrors for Tarvia, because when it is used as a binder it forms a tough matrix for the crushed stone. Not only has Tarvia greater bonding power than natural binder, but it has the further element of *plasticity*, so that it yields instead of crumbling.

Tarvia solves motor-traffic problems.

The use of Tarvia reenforces the road-surface and makes it strong enough to resist motor-driven traffic, which to-day is the biggest problem of the roadmaker.

Likewise with the erosion problem: Water on steep grades washes out plain macadam but does not harm the Tarvia-macadam because it is absolutely waterproof.

And remember, Tarvia roads are also *frost-proof, mudless, and dustless,* and cost less than any other type of good-road construction.

Illustrated booklet describing the various Tarvia treatments free on request.

The Barrett Company LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER
ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

Summit Crescent, West Crescent Height, Westmount, a suburb of Montreal. Treated with Tarvia.

Special Service Department

This company has a corps of trained engineers and chemists who have given years of study to modern road problems. The advice of these men may be had for the asking by any one interested. If you will write to the nearest office regarding road problems and conditions in your vicinity, the matter will have prompt attention.

Main Driveway, Queen Victoria Park, Niagara Falls, Ont., north of the Administration Building.

saw mill, stave and lath mill, planing mill, flour mill, foundry and, perhaps, a new toy factory. W. C. Trapp, managing director.

Cornwall, Ont.—A terminal pulp company will operate from Cornwall, if bonds are guaranteed. This company will handle pulpwood and lumber from the forests of Quebec and New Brunswick destined for pulp mills in New York State. H. Dow, reeve, township of Cornwall.

Cornwall, Ont.—Tenders will be received until 12 o'clock noon, August 12th, by the department of railways and canals, Ottawa, for the rebuilding and extension of wharf, lock 17-18 level. Plans, etc., at the offices of the chief engineer, Ottawa; superintending engineer, Cornwall, Ont. J. W. Pugsley, secretary.

Fort William, Ont.—The Ogilvie Flour Mills Co. will construct a new concrete dock along the waterfront of the company on the Kaministiquia River.

Fort William, Ont.—Pavement on Victoria Ave. will soon be relaid by the department of works. Concrete and dollarway has been recommended by the city engineer.

Glace Bay, N.S.—Bate-McMahon Co. have resumed their contract for loading gravel at Dixon's platform, loading at the rate of 300 tons per day.

Hamilton, Ont.—The board of harbor commissioners will request the Dominion government to make an early start on the harbor improvement program for which appropriation was made recently.

Marysville, N.B.—The Ambursen Hydraulic Construction Co., of Canada, Ltd., has been awarded contract for a dam and water power development for the Nashwaak Pulp and Paper Co., Ltd.

Midland, Ont.—Contract has been awarded by the department of public works, Ottawa, to W. H. McArdle, Midland, for repairs to wharf. Contract price, $3,291.30. R. C. Desrochers, secretary.

Midland, Ont.—Contracts have been awarded by the department of public works, Ottawa, for renewals to government wharfs Nos. 1 and 2 at Midland, to Wm. Henry McArdle, Midland, Ont. Secretary, R. C. Desrochers.

Midland, Ont.—Tenders will be received until 5 p.m., August 1st, by the town council for excavating, laying and backfilling 790 lin. ft. of sewer. Tenders will also be received for the above work, including supply of 8-in. tile and tees. C. E. Smith, town clerk.

Moncton, N.B.—City council has decided to extend the water mains to Georgetown, installing a 12-in. main. Mayor Price.

Montreal, Que.—Contract has been awarded to the Raymond Concrete Pile Co., Ltd., Montreal, for the piling required for the Nurses' Home, Western Hospital, Montreal.

Montreal, P.Q.—Wonham, Bates and Goode, Inc., Montreal, have sold a 15-ton, eight wheel Orton and Steinbrenner locomotive crane, with 40-in. electric magnet, to the Canadian Rolling Mills.

Moose Jaw, Sask.—The Romans' Machine and Repair Co., have applied to the city council for permission to use the buildings formerly occupied as munition plant to operate an iron and brass foundry.

Nanaimo, B.C.—The Nanaimo Automobile Club will urge the construction of an automobile elevator to be installed at the docks for use at low tide. J. F. Edge-Partington, secretary.

Odessa, Ont.—Tenders will be received until 12 o'clock noon, August 8th, by the department of public highways, Toronto, for construction of the concrete abutments, concrete roadway and sidewalk floors for bridge. Plans, etc., at the office of the resident engineer, Napanee; city engineer, Kingston, and department of highways, Toronto. W. A. McLean, deputy minister. (Official advertisement in this issue.)

Ottawa, Ont.—Contract has been let by the department of public works for supply of electric fixtures and lamps for the Hunter building, Ottawa, to A. A. Giddings and Co., Montreal. Contract price, $9,981.45. Tenders received ranged from $9,981.45 to $13,194. R. C. Desrochers, secretary.

Ottawa, Ont.—Tenders will be received until August 30th for pumps, engines, blowers, boilers, radiators and various other unused articles, now at the Kingston Penitentiary, Kingston, Ont. W. S. Hughes, Superintendent of Penitentiaries, Department of Justice, Ottawa. (See official advertisement on another page of this issue.)

Ottawa, Ont.—The following item appeared in this column in the July 17th issue: "Contract for dredges P.W.D. No. 110 and P.W.D. No. 116 has been awarded by the Department of Public Works to M. Beatty & Sons, Ltd., Midland, Ont." There were two errors in this item. The address of M. Beatty & Sons, Ltd., is Welland, Ont., not Midland. The contract was not for dredges, but for three dipper handles, two for dredge No. 110 and one for dredge No. 116.

Owen Sound, Ont.—By-law has been introduced for concrete curbs on several streets. C. H. Thompson.

Pictou, N.S.—Tenders will be received until 9 o'clock a.m., August 7th, for the plumbing and heating; electric wiring and installation of fixtures in connection with the construction of the new county asylum. J. W. McKay, architect. A. MacDougall, secretary of building commission, Pictou, N.S.

Port Elgin, Ont.—Tenders will be received until 12 o'clock noon, August 5th, by the department of public works, Ottawa, for repairs to breakwater. Plans, etc., at the office of the district engineer, Toronto, and at the post-office, Port Elgin, Ont. R. C. Desrochers, secretary.

St. John, N.B.—Contracts for supply of materials have been awarded by the city council as follows: valves, taps and boxes to Drummond McCall Co.; castings to James Fleming; cast-iron pipe to Vroom and Arnold; and lead pipe and leadite to James Roberston Co., Ltd.

St. John, N.B.—Contract has been awarded by the department of public works, Ottawa, for post office fittings, to John Flood and Sons, St. John, N.B. Contract price, $1,950. R. C. Desrochers, secretary.

St. John, N.B.—Contracts have been awarded by the department of works for the following excavations: East St. John, to Moses and Tobias, of St. John, N.B. Rejected tender from Lewis and Thomas Stephen and the New Brunswick Contracting and Building Co., St. John. Brussels and King Sts., to Tobias and Farris; City Rd., Duke St. and Douglas Ave., to the New Brunswick Contracting and Building Co.; sewer excavation in Douglas Ave., to Lewis and Thomas Stephen. G. G. Hare, city engineer.

St. John, N.B.—The following tenders were received by the city council and referred to Commissioner Jones for report: St. John Iron Works.—Gate valves, 16-in. to 6-in., $160, $82, $36, $41, $28, $178.50, $91.35, $70.10, $46, $31.45. Special castings, 5 cents per lb. Union Foundry and Machine Works.—Special castings, 8 cents per lb.; service and curb boxes, $4.90 and $2.80, respectively. Hall Machinery Co., Sherbrooke, Que.—Cast iron pipe, $50 per ton. Special castings, 5¾ cents per lb.; both f.o.b. New Jersey, U.S.A. A. R. Williams Machinery Co.—Gate valves, $135, $62.40, $37.60, $22.40. T. McAvity and Sons, Ltd.—Five hydrants, $110 each. Gate valves, $165, $75, $54, $32.40, $19.50. Stop cocks, $3.05, $2.70, $1.45. Service boxes, $10.75. Lead pipe, 12½ cents per lb. Leadite, 16 cents per lb. Vroom and Arnold.—Cast iron pipe, $66.50 per ton; special castings, 7½ cents per lb. Drummond McCall, Montreal.—Market price at time of order. James Robertson and Co., Ltd.—Gate valves, $178.40, $89.26, $64.34, $36.87, $22.23; leadite, 15¾ cents per lb. Phœnix Foundry.—Gate valves, $170.85, $61.50, $35, $21.50; special castings, 7 cents per lb.; hydrants, $97.50; stop cock boxes, $5 each. Estey and Co.—Cast iron pipe, $57.25 per ton; fittings, $110 per ton. Canadian Fairbanks Morse, Ltd.—Gate valves, $201.80, $80, $57.60, $34.56, $20.80; fire hydrants, $87.48.

Toronto, Ont.—Contract has been awarded by the department of public works, Toronto, to the Dufferin Construction Co., Toronto, for the excavation work on Rouge Hill, county of Pickering. Excavation will be commenced about August 1st, and be completed this fall. W. A. McLean, deputy minister highway department.

Toronto, Ont.—Contract has been awarded by the Hydro-Electric Power Commission of Ontario to M. Beatty & Sons, Ltd., Welland, Ont., for two 80 h.p. triple drum electric hoists, two 80 h.p. double drum electric hoists, and four 10 h.p. triple-geared independent electric boom swingers. This

machinery is for use on the new power canal being built by the Commission in connection with the Chippewa-Queenston hydro-electric power development.

Toronto, Ont.—Tenders will be received until 12 o'clock noon, August 19th, by the department of public highways, Toronto, for the construction of concrete structures on the provincial highway from Cobourg to Port Hope. Plans, etc., at the office of the resident engineer, Port Hope, and at the department, Toronto. (Official advertisement in this issue.) W. A. McLean, deputy minister.

Toronto, Ont.—Tenders will be received until 12 o'clock noon, August 25th, by the Canadian National Railways, for 1,375,000 railway ties. Delivery to be on C.N. Ry. lines as follows:—1,000,000, Port Arthur to Pembroke; 50,000, Central Ontario; 25,000, Ottawa to Quebec; 200,000, O'Brien to Quebec; 100,000, Lake St. John district. E. Langham, general purchasing agent.

Toronto, Ont.—The board of control has authorized the Parks Commissioner to purchase additional park seats, cost $1,654, and one thousand chairs, cost $1,110, for use at Exhibition Park.

Township of Dover, Ont.—Tenders will be received until 6 p.m., August 2nd, for construction of a dash wheel, pump-house and concrete wheel-pit at Myers' Pumping Works. J. St. Pierre, Bear Line, Ont., R.R. No. 1.

Vancouver, B.C.—Contract has been awarded to the Sidney E. Junkins Co., Ltd., for construction of the concrete lining in the Connaught tunnel of the Canadian Pacific Ry.

Vancouver, B.C.—Tenders will be called until 12 o'clock noon, August 5th, for supply of a new 1,000-gallon gasoline pumping engine for the fire department. James Stuart, purchasing agent.

Victoria, B.C.—The D'Arcy Oil Co. have applied to the provincial government for permission to prospect for oil. If successful, a pipe line would be laid from the Peace River to the coast. Estimated cost, $25,000,000.

Windsor, Ont.—The city council contemplate buying two motor truck street flushers. Estimated cost, $20,000. M. A. Dickenson, acting clerk.

Winnipeg, Man.—Tenders will be received by the Greater Winnipeg Water District until noon, September 1st, for apparatus which will indicate at the head office of the District the water level in the District's surge tank at St. Boniface. R. D. Waugh, chairman of commissioners, 501 Tribune Building, Winnipeg.

ADDITIONAL TENDERS PENDING

Not Including Those Reported in This Issue

Further information may be had from the issues of *The Canadian Engineer*, to which reference is made.

Tenders Called For

TENDERS FOR BRIDGES

Sealed tenders, plainly marked as to contents, addressed to the undersigned, will be received up to 2 p.m. on Monday, August the 11th, 1919, for the construction of the following reinforced cement concrete culverts, bridges and abutments:—

(1) Located in the County of Dufferin—
1 culvert 4-foot span.
4 culverts 6-foot "
1 culvert 8-foot "
7 bridges 10-foot "
2 bridges 12-foot "
1 bridge 14-foot "
1 bridge 16-foot "
1 bridge 20-foot "
1 bridge 22-foot "
3 bridges 24-foot "

(2) Located in the Township of Albion—
1 pair of abutments for a 55-foot steel truss.
1 " " " " " 48-foot " "

(3) Located in the Township of Toronto Gore—
1 bridge 32-foot span.

(4) Located in the Township of Toronto—
1 bridge 12-foot span.

Plans and specifications may be seen and forms of tender and all information obtained at the office of the undersigned.

The lowest or any tender not necessarily accepted.

WHEELOCK & CHRISTIE,
Civil Engineers,
Orangeville, Ont. 314

TOWNSHIP OF YORK

TENDERS FOR CONCRETE SIDEWALKS

Sealed tenders, plainly marked as to contents, will be received by the undersigned up to 10 o'clock of Tuesday, August 5th, 1919, for the construction of concrete sidewalks on Westwood and Hillbrow Avenues, in the Township of York.

Plans and specifications may be seen at the office of the undersigned, 40 Jarvis St., Toronto.

The lowest or any tender will not necessarily be accepted.

FRANK BARBER,
Township Engineer.
Toronto, July 23rd, 1919. 312

NOTICE TO CONTRACTORS

Sealed tenders, marked "Tenders for Concrete Structures," will be received by the undersigned until 12 o'clock noon on Tuesday, August the 19th, 1919, for the construction of the concrete structures on the Provincial Highway from Cobourg to Port Hope.

Plans, specifications and forms of tender may be seen on and after Tuesday, August the 5th, 1919, at the Office of the Resident Engineer, Port Hope, and at the Office of the undersigned.

A marked cheque for Five Hundred Dollars, payable to the Minister of Public Works and Highways, Ontario, must accompany each tender.

The lowest or any tender not necessarily accepted.

W. A. McLEAN,
Deputy Minister of Highways.
Department of Public Highways,
Toronto, July the 29th, 1919. 315

The Canadian Engineer

A Weekly Paper for Civil Engineers and Contractors

Riveted Joints for Steel Penstocks and Tanks

Formulae and Tables for Their Design—Selection of Proper Type of Joint—Examples of Solution for Maximum Joint Efficiency — Discussion of the Heavier Types, Including Triple, Quadruple and Quintuple Riveted Butt and Double Strap Joints

By H. A. BABCOCK and J. R. MONTAGUE
Hydraulic Engineering Department, Hydro-Electric Power Commission of Ontario

IN this paper the writers have endeavored to outline in a clear and practical way the essential points in connection with the choice and design of riveted joints in steel plate cylinders.

Very little is to be found in engineering texts on the design of the heavier type of riveted joints, that is the triple, quadruple and quintuple riveted butt and double strap joints. It is therefore hoped that the section of this paper covering that portion of the work may be of considerable interest to designers.

The selection of the proper type of joint to be used in any particular case, will first be discussed, followed by the method of design, numerical examples, and tables giving the dimensions recommended by the Hartford Steam Boiler Inspection & Insurance Co. for the various types of joints.

Nomenclature

e = Efficiency of joint, expressed in decimals.
f = Tensile strength of plate, in pounds per square inch.

FIG. 1—EUGENIA FALLS PENSTOCK, 54-INS. DIAMETER, WITH TRIPLE-RIVETED BUTT JOINT ON LONGITUDINAL SEAM AND DOUBLE-RIVETED LAP ON GIRTH SEAM

t = Plate thickness, in inches.
b = Butt strap thickness, in inches.
P = Pitch of rivets, in inches, in row having greatest pitch.
d = Rivet diameter after driving, in inches.
D = Internal diameter of cylinder, in inches.
a = Cross-sectional area of rivet after driving, in square inches.
s = Ultimate strength of rivets in single shear, in pounds per square inch.
S = Ultimate strength of rivets in double shear, in pounds per square inch.
p = Internal pressure, in pounds per square inch.

Selecting Proper Type of Joint

Where the thickness of the plate is dependent upon factors other than the internal pressure, such as rigidity of the section against collapsing, the type of joint depends

FIG. 2—DOUBLE-RIVETED LAP JOINT IN 18-FT. DIAMETER PIPE, ONTARIO POWER CO.

largely on the effiiciency required. To determine the efficiency, the following formula may be used:—

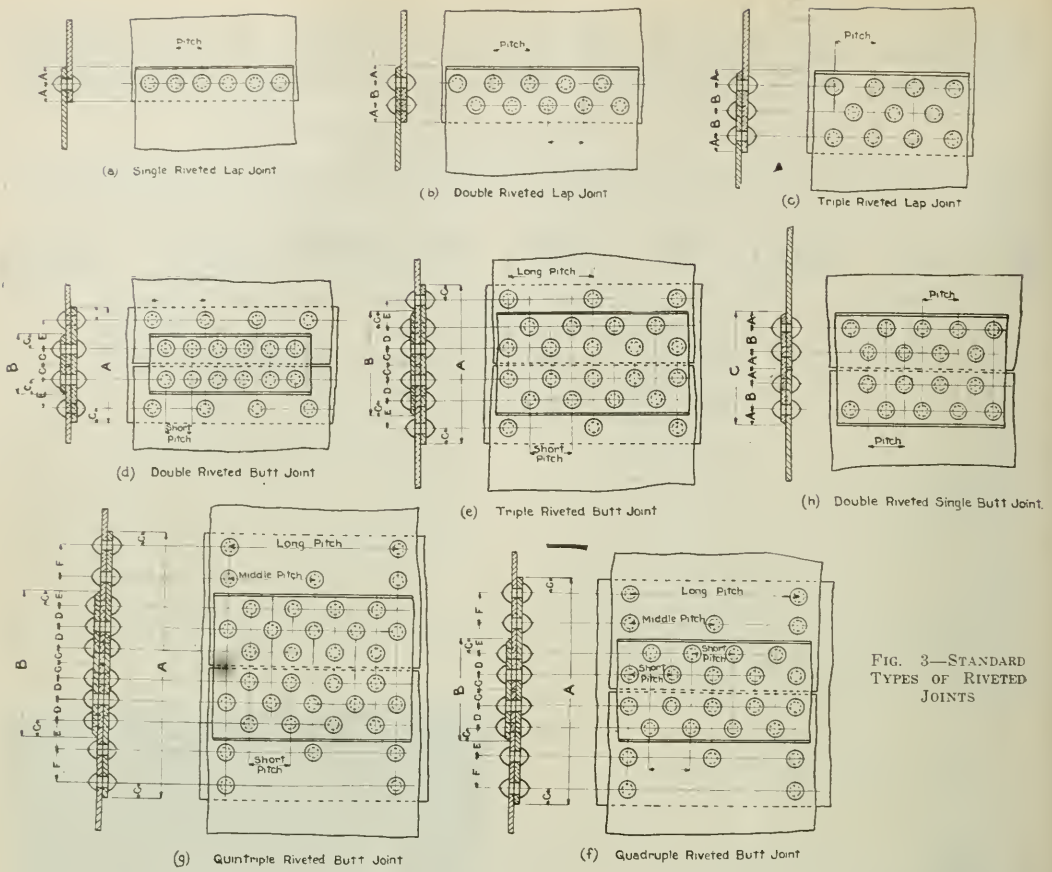
$$e = pD\ 2ft.$$

Having thus determined the efficiency, and knowing the thickness of plate, the proper type of joint can be selected from the accompanying standard charts, or it can be designed by the methods given in the latter part of this paper.

Where the plate thickness is governed by internal pressure, for a pipe of given diameter, the problem resolves itself into one of choosing that type of joint which will give the most economical pipe section. This is not always accomplished by using the most efficient joint, as will be pointed out later.

Riveted Lap Joints

On girth seams, the single riveted lap joints are sometimes used, particularly in the case of small diameter pipes, but are not to be recommended for pipes over 5 ft. in diameter.



Pitch
(a) Single Riveted Lap Joint
(b) Double Riveted Lap Joint
(c) Triple Riveted Lap Joint
Long Pitch
Short Pitch
(d) Double Riveted Butt Joint
(e) Triple Riveted Butt Joint
(h) Double Riveted Single Butt Joint.
Middle Pitch
(g) Quintriple Riveted Butt Joint
(f) Quadruple Riveted Butt Joint

FIG. 3—STANDARD TYPES OF RIVETED JOINTS

They are seldom used in longitudinal seams unless the pressure is very light and the pipe diameter small. Under high presures there is a tendency for the joint to buckle, as shown in Fig 6. It is apparent that such a tendency is very undesirable as far as watertightness is concerned. Single riveted lap joints are used almost exclusively in spiral riveted pipe, in which case they are satisfactory.

Double riveted lap joints are used very largely in girth seams, especially in large diameter pipes. Their use in longitudinal seams is quite satisfactory for pipes up to 8 ft. in diameter where they fulfill the requirements of efficiency and rigidity of section. When propertly caulked, they can be made entirely watertight. In girth seams, they are usually designed with the same diameter of rivet as is used in the adjacent longitudinal seams, for the sake of simplicity.

Triple riveted lap joints are far more satisfactory in longitudinal seams than either single or double riveted lap joints, because of their greater rigidity and consequent watertightness. For pipe diameters greater than 4 ft., they are uneconomical except where the required joint efficiency is not more than 75%.

FIG. 4—PENSTOCK, 10-FT. DIAMETER, WITH SINGLE-RIVETED LAP JOINTS (AT HANNAWA FALLS, N.Y.)

It should be borne in mind that in no case should a lap joint be used for joining plates more than ½ in. in thickness, except in the case of circumferential joints.

Riveted Butt and Double Strap Joints

Double riveted butt joints are especially recommended for longitudinal seams where joint efficiency is not a prime factor, but where watertightness is essential. This is evident from the fact that the narrow strap has a well supported caulking edge, the pitch of rivets in the second row being much less than in either the double or triple riveted lap joints, as can be seen from the accompanying tables. In all butt strap joints, the narrow strap should be placed on the outside of the pipe. While both straps may be caulked, the narrow strap is the principal one in making the joint water tight, and must be accessible for recaulking in case a leak develops in testing.

Triple riveted butt joints are used in longitudinal seams where the required efficiency cannot be satisfied by any of the simpler joints; or they should be used in the smaller diameter pipes where the increased cost of a quadruple riveted butt joint is more than the saving in the metal effected by its higher efficiency.

TABLE 1—SINGLE RIVETED LAP JOINTS*

Thickness of Plate	Diameter of Rivet Holes	Efficiency %	Pitch	A	Method of Failure
¼"	11/16"	60.7	1¾"	1 1/16"	T.P.
9/32"	11/16"	60.3	1¾"	1 1/16"	S.R.
5/16"	13/16"	59.4	2"	1¼"	T.P.
11/32"	13/16"	59.4	2"	1¼"	T.P.
3/8"	15/16"	58.3	2¼"	1 7/16"	T.P.
13/32"	15/16"	58.3	2¼"	1 7/16"	T.P.
7/16"	1 1/16"	57.5	2½"	1⅝"	T.P.
15/32"	1 1/16"	57.5	2½"	1⅝"	T.P.
½"	1 1/16"	56.7	2½"	1⅝"	S.R.

*Joint efficiencies in Tables 1 to 6 are computed upon the following basis:—Tensile strength of plate = 55,000 lbs. per sq. in.; resistance to crushing of plate = 95,000 lbs. per sq. in.; strength of rivets in single shear = 44,000 lbs. per sq. in. In the columns headed "Method of Failure," T.P. indicates that the joint will fail by tearing the plate in the net section between rivet holes, and S.R. means that the failure will be due to shearing of rivets.

TABLE 2—DOUBLE RIVETED LAP JOINTS

Thickness of Plate	Diameter of Rivet Holes	Efficiency %	Pitch	A	B	Method of Failure
¼"	11/16"	69.5	2¼"	1 1/16"	1¾"	T.P.
9/32"	11/16"	69.5	2¼"	1 1/16"	1¾"	T.P.
5/16"	13/16"	69.1	2⅝"	1¼"	1⅞"	T.P.
11/32"	13/16"	69.1	2⅝"	1¼"	1⅞"	T.P.
3/8"	15/16"	68.9	3"	1 7/16"	2"	T.P.
13/32"	15/16"	68.9	3"	1 7/16"	2"	T.P.
7/16" ....1 1/16"		68.5	3⅜"	1⅝"	2⅛"	T.P.
15/32" ....1 1/16"		68.5	3⅜"	1⅝"	2⅛"	T.P.
½" ....1 1/16"		68.5	3⅜"	1⅝"	2⅛"	T.P.

Quadruple riveted butt joints are used where maximum efficiency is required in the longitudinal seams of pipes having a diameter of 4½ ft. or more. For smaller diameters, it would be advisable to compute the cost of pipe per foot of length for both quadruple and triple riveted butt joints, and for very small diameters it would be well to consider also the double riveted butt joint.

Occasionally resort is made to quintuple riveted butt joints where a very high efficiency is essential, due to a necessary limit to the thickness of plate used, but on account of higher cost and increased resistance to the flow of water, their use in pipe should be avoided if possible. They may be found economical for use in the joints of tanks and standpipes, where friction is a negligible factor.

Another type of joint coming into more general use, especially for girth seams, is the single strap double riveted butt joint. The strap is made the same thickness as the main plates, and its mathematical treatment is the same as that of a double riveted lap joint. Its particular advantages lie in the smooth surface it presents on the inside of the pipe and, in girth seams, in the use of pipe sections having constant diameter.

Joint Efficiency Principal Consideration

The principal consideration entering into the design of a riveted joint is the determination of joint efficiency. Joint efficiency may be defined as the ratio of the strength of the joint to the strength of the uncut plate, and is usually expressed in percentage. The following formulæ may be used to determine the efficiency of the different types of joints:—

FIG. 5—BIG CHUTE PENSTOCK, 9-FT. DIAMETER, WITH SINGLE AND DOUBLE-RIVETED LAP JOINTS

Formulæ for Riveted Lap Joints

A = Strength of solid plate.
= Ptf.
B = Strength of plate between rivet holes.
= $(P-d)tf$.
C = Shearing strength of one rivet in single shear for single-riveted, of two rivets in single shear for double-riveted, or of three rivets in single shear for triple-riveted.
= nsa.
D = Crushing strength of plate in front of one rivet for single-riveted, of two rivets for double-riveted, or of three rivets for triple-riveted.
= $ndtc$.

To obtain the joint efficiency, divide B, C or D, whichever is the least, by A.

Formulæ for Riveted Butt and Double Strap Joints

A = Strength of solid plate.
= Ptf.
B = Strength of plate between rivet holes in the outer row.
= $(P-d)tf$.
C = Shearing strength of two rivets in double shear for double-riveted, of four rivets in double shear for triple-riveted, or of eight rivets in double shear for quadruple-riveted, plus the shearing strength of one rivet in single shear for double and triple riveted and three rivets in single shear for quadruple riveted.
= $NSa+nsa$.
D = Strength of plate between rivet holes in the second row, plus the shearing strength of one rivet in single shear in the outer row.
= $(P-2d)tf+nsa$.

E = Strength of plate between rivet holes in the second row, plus the crushing strength of butt strap in front of one rivet in the outer row.
= $(P-2d)tf+dbc$.

F = Crushing strength of plate in front of two rivets for double-riveted, of four rivets for triple-riveted, or of eight rivets for quadruple-riveted, plus the crushing strength of butt strap in front of one rivet for double-riveted, of one rivet for triple-riveted, or of three rivets for quadruple-riveted.
= $Ndtc+ndbc$.

G = Crushing strength of plate in front of two rivets for double-riveted, of four rivets for triple-riveted, or of eight rivets for quadruple-riveted, plus the shearing strength of one rivet in single shear for double-riveted, of one rivet in single shear for triple-riveted, or of three rivets in single shear for quadruple-riveted.
= $Ndtc+nsa$.

H = Strength† of plate between rivet holes in the third row, plus the shearing strength of two rivets in the second row in single shear and one rivet in single shear in the outer row.
= $(P-4d)tf+nsa$.

I = Strength† of plate between rivet holes in the third row, plus the crushing strength of butt strap in front of two rivets in the second row and one rivet in the outer row.
= $(P-4d)tf+ndbc$.

To obtain the joint efficiency, divide A, B, C, D, E, F, G, H or I, whichever is the least, by A.

The first step in the design of a riveted joint for a given thickness of plate is to assume a rivet diameter within the limits given in Table 8, and with this diameter, various values for the pitch of rivets, within the limits described below, should be tried out until that pitch which gives a maximum joint efficiency is obtained. Having determined the proper pitch for a given rivet diameter, the same process should be repeated using various rivet diameters until that combination of pitch and rivet diameter which will give the maximum efficiency, is obtained. A fairly broad range of rivet diameters may be used, the limits for a given plate thickness being shown in Table 8.

TABLE 3—TRIPLE RIVETED LAP JOINTS

Thickness of Plate	Diameter of Rivet Holes	Efficiency %	Pitch	A	B
3/8"	13/16"	75	3 1/4"	1 1/4"	2 1/8"
7/16"	15/16"	75	3 3/4"	1 7/16"	2 3/8"
1/2"	15/16"	75	3 3/4"	1 7/16"	2 3/8"

Pitch of Rivets

The maximum pitch of rivets is controlled by the limits for caulking along the joint having shortest pitch (see Fig. 3). It is evident that if the pitch (or short pitch in the case of butt joints) is very great in proportion to the thickness of the plate or butt strap, there will be a tendency for the plates to spring apart between rivets. This maximum distance is one which is difficult if not impossible to determine analytically, but which has been found in practice to conform very closely to values given in Tables 1 to 6. In the case of lap joints, the maximum pitch for various combinations of plate thickness and rivet diameter is given in Table 7. For butt strap joints, the values for short pitch given in Tables 4 to 6 should not be exceeded except according to the following rules:—

Rule 1.—The short pitch *may* be increased by 1½ times any increase in rivet diameter plus 1½ times any increase in butt strap thickness.

Rule 2.—Should either the rivet diameter or butt strap thickness be decreased below the values given in Tables 4 to 6, the short pitch *must* be decreased by 1½ times the change in rivet diameter plus 1½ times the change in butt strap thickness.

The minimum pitch of rivets for either lap or butt strap joints can be obtained from Fig. 3 for various distances between gauge lines, and vice versa. The distances between gauge lines given in Fig. 7, while not rigidly adhered to in all cases, are based on the recommended minimum distance between rivets for good shop practice. To go below this minimum distance may mean the use of special rivet dies for driving the rivets, for quadruple or quintuple riveted butt joints, tance between gauge lines is usually made greater than the allowable minimum, for convenience in assembling and riveting the joints.

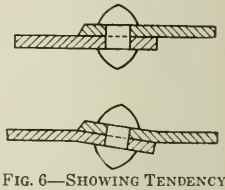


FIG. 6—SHOWING TENDENCY OF SINGLE-RIVETED LAP JOINT TO BUCKLE OR TWIST

On butt strap joints the dimension E is determined by adding to dimension C one-half the diameter of a standard rivet die for the particular size of rivet used, plus 1/16 in. for clearance.

Expressing this as a formula:—

$E = C + (\frac{1}{2}\text{diameter of rivet die}) + \frac{1}{16}$ in.

The dimension F between the first and second rows of rivets, for quadruple or quintuple riveted butt joints, should not be less than that given in Table 6, for given rivet diameters and butt strap thicknesses.

TABLE 4—DOUBLE RIVETED BUTT JOINTS*

Thickness of Plate	Thickness of Strap	Diameter of Rivet Hole	Efficiency %	Long Pitch	Short Pitch	A	B	C	E
1/4"	1/4"	11/16"	82.8	4"	2"	8 1/2"	4 1/4"	1 1/16"	2 1/8"
9/32"	1/4"	11/16"	82.8	4"	2"	8 1/2"	4 1/4"	1 1/16"	2 1/8"
5/16"	9/32"	13/16"	81.9	4 1/2"	2 1/4"	9 7/8"	5"	1 1/4"	2 7/16"
11/32"	9/32"	13/16"	81.9	4 1/2"	2 1/4"	9 7/8"	5"	1 1/4"	2 7/16"
3/8"	5/16"	13/16"	81.9	4 1/2"	2 1/4"	9 7/8"	5"	1 1/4"	2 7/16"
13/32"	5/16"	13/16"	81.9	4 1/2"	2 1/4"	9 7/8"	5"	1 1/4"	2 7/16"
7/16"	3/8"	15/16"	81.3	5"	2 1/2"	11 1/4"	5 3/4"	1 7/16"	2 3/4"
15/32"	3/8"	15/16"	81.3	5"	2 1/2"	11 1/4"	5 3/4"	1 7/16"	2 3/4"
1/2"	7/16"	15/16"	81.3	5"	2 1/2"	11 1/4"	5 3/4"	1 7/16"	2 3/4"

*All joints in above table fail by tearing the plate between rivet holes in the outer row. For convenience in driving rivets, the back-pitch (dimension E) may be increased if desired without affecting the joint efficiency, but it should not be decreased.

Thickness of Butt Strap

The thickness of butt strap should be chosen so that the net section along the inner row of rivets has sufficient area to take in tension the total force carried by the joint. The formula.

$$b = [P/2(P-nd)]te,$$

where n = number of rivets in distance P on inner row, will give the required thickness of each butt strap.

General Remarks

The dimensions for riveted joints given in Tables 1 to 6, both inclusive, are those recommended by the Hartford Steam Boiler Inspection & Insurance Co., and are computed upon the following basis:—

Tensile strength of plate = 55,000 lbs. per sq. in.
Resistance to crushing of plate = 95,000 lbs. per sq. in.
Strength of rivets in single shear = 44,000 lbs. per sq. in.
Strength of rivets in double shear = 88,000 lbs. per sq. in.

In cases where different stresses are used, the efficiency may vary accordingly, and should be computed for the new condition. The dimensions for pitch and spacing between rows of rivets are based on well-recognized standards and should be adhered to as closely as possible.

The formulæ for obtaining joint efficiency are based

†For quadruple-riveted and quintuple-riveted butt and double strap joints only.

TABLE 5—TRIPLE RIVETED BUTT JOINTS*

*Joints for plate thickness from 27/32" to 1" (both inclusive) fail by tearing the plate between rivet holes in the second row and shearing a rivet in the outer row. This also applies to the joint for the 3/4" plate. All other joints in the above table fail by tearing the plate between rivet holes in the outer row. For convenience in driving rivets, either of the dimensions for back-pitch (D and E) may be increased without affecting the joint efficiency, but not decreased.

on the rules formulated by the Massachusetts Board of Boiler Rules.

Numerical Examples

Design of a triple-riveted lap joint for a 7/16-in. plate.

From Table 8, the sizes of rivets that may be used in 7/16-in. plates range from 5/8-in. to 1 1/4-ins.

FIG. 8—ONTARIO POWER CO.'S TANK, 60-FT. DIAMETER, WITH QUADRUPLE-RIVETED BUTT JOINTS ON LONGITUDINAL SEAMS AND SINGLE-RIVETED LAP ON GIRTH SEAMS

First trial: Assume the same size and pitch of rivets as shown in Table 3, that is 7/8 in. diameter and a pitch of 3 3/4 ins. Then

t = 7/16 in. = 0.4375 in.
P = 3 3/4 ins. = 3.75 ins.
d = 15/16 in. = 0.9375 in.
a = 0.6903 sq. in.
f = 55,000 lbs. per sq. in.
s = 44,000 lbs. per sq. in.
c = 95,000 lbs. per sq. in.

From the formulae for determining the efficiency of lap joints, we have:—

TABLE 6—QUADRUPLE RIVETED BUTT JOINTS*

1 1/4"	7/8"	17/16"	86.8	20"	10"	5"	30 5/8"	14 1/2"	2 3/16"	2 7/8"	3 3/4"	4 5/16"

*Joints for plate thickness from 27/32" to 1 1/4" (both inclusive) fail by tearing the plate between rivet holes in the third row and shearing the rivets in the outer two rows. This also applies to the joint for 3/4" plate. All other joints in the above table fail by tearing the plate between rivet holes in the outer row. For convenience in driving rivets, any of the dimensions for back-pitch (dimensions D, E and F) may be increased, if desired, without affecting the joint efficiency, but they should not be decreased.

$A = Ptf = 3.75 \times 0.4375 \times 55{,}000 = 90{,}234.$
$B = (P-d)tf =$
$(3.75-0.9375) \times 0.4375 \times 55{,}000 = 67{,}677.$
$C = nsa = 3 \times 44{,}000 \times 0.6903 = 99{,}120.$
$D = ndtc = 3 \times 0.9375 \times 0.4375 \times 95{,}000 = 116{,}689.$
$e = B/A = 0.75 = 75\%.$

Second trial: Assume the same diameter of rivet and a pitch of 3⅝ ins. Then $P = 3.625$ ins., and
$A = Ptf = 3.625 \times 0.4375 \times 55{,}000 = 87.338.$
$B = (P-d)tf =$
$(3.625-0.9375) \times 0.4375 \times 55{,}000 = 64{,}669.$
$C = nsa = 3 \times 44{,}000 \times 0.6903 = 99{,}120.$
$D = ndtc = 3 \times 0.875 \times 0.4375 \times 95{,}000 = 109{,}102.$
$e = B/A = 0.74 = 74\%.$

Third trial: Assume the same diameter of rivet and a pitch of 3⅞ ins. Then $P = 3.875$ ins., and
$A = Ptf = 3.875 \times 0.4375 \times 55{,}000 = 93{,}242.$
$B = (P-d)tf =$
$(3.875-0.9375) \times 0.4375 \times 55{,}000 = 70{,}684.$
$C = nsa = 3 \times 44{,}000 \times 0.6903 = 91{,}120.$
$D = ndtc = 3 \times 0.875 \times 0.4375 \times 95{,}000 = 109{,}112.$
$e = B/A = 0.758 = 75.8\%.$

From the above, it is seen that by increasing the pitch of the rivets, an increase in the efficiency of the joint is obtained. However, the pitch of the rivets is limited to that which will permit water-tight caulking. In this case the pitch should not exceed 3¾ ins. (see Table 7), and hence the maximum efficiency attainable with a ⅞-in. rivet is 75%.

The process should be repeated, using different sizes of rivets and various pitches. That combination of rivet diameter and pitch that gives the greatest efficiency, and does not exceed the maximum rivet spacing prescribed in Table 7, is the most desirable.

WATER PURIFICATION UNITS MOUNTED ON MOTOR TRUCKS*

By William J. Orchard
Sanitary Engineer, Wallace & Tiernan Co., Inc., New York City

In every line of endeavor, the world war brought forth many novel developments, and although the water supply field was but one of the many, it is pleasing to present before this convention of water works men, a discussion of the units developed and manufactured by members of this association, to be operated in France, and elsewhere, by other members engaged in delivering safe water supplies to the allied military forces.

The portable, motor-truck-mounted, water-purification units about to be described, present nothing new in the fundamental principles of water purification, but show the applicability of the principles used in stationary domestic plants, to portable plants for military use.

In 1914, the necessity for a specially organized water service was not recognized by any of the allied forces, water supply functions being the duty of engineering troops. The purity of the water was determined by the medical department.

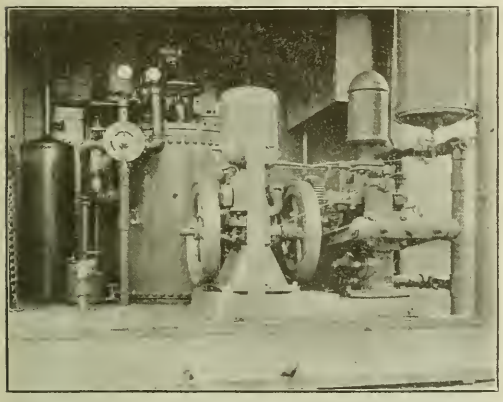

Fig. 1—Rear of Completed Truck, Showing Filters, Power Plant, Pump, etc.

The water supply conditions presented in France and in Belgium, and the problems of water supply met in trench warfare, were entirely different from problems presented in previous wars. The soils of Northern France and Belgium were for the most part highly cultivated, fertilized for scores of years with night soil and other refuse, so that water supplies normally obtained in the battle area were highly polluted. Then, too, the German forces, in passing over the country, indescribably polluted all water left behind when retreating, making special measures necessary for purification.

It is reliably reported that the 1915 Champaign campaign of the French army broke down largely due to inadequacy of water supply arrangements, and at the close of this campaign, the French war office organized a special water service for the Second French Army, under the direction of Major Bunau-Varilla, well-known through his endeavors to construct the Panama Canal with French financial support.

The chlorination of all water supplies used for drinking and cooking purposes, was required by the French military authorities. Calcium hypochlorite or sodium hypochlorite was applied in such quantities that fifteen minutes after treatment there remained two-tenths parts per million of residual chlorine.

*Paper prepared for the recent Buffalo Convention of the American Water Works Association.

It should be pointed out that such excessive amounts of residual chlorine, greatly in excess of American practice, left objectionable tastes and odors in the treated water, so that the troops were apt to take the more palatable, but dangerous, untreated water from flowing streams, shell holes and the like, when possible.

The United States forces, in entering the conflict, taking advantage of the lessons learned by the allied forces, created a water supply regiment, the 26th Engineers, which was

Fig. 2—Ready for a Long Journey

officered by experienced water works men, most of whom are members of the American Water Works Association. This regiment had charge of the water supply of the American Forces, both in the advanced area and in the rear.

Early in the war, the need for portable water wagons for the purification of supplies, was presented, and bulky equipment, with filters and devices for treating the water with hypochlorite, were put forth. In 1916, the availability of apparatus of American manufacture to control liquid

Fig. 3—End and Side Gates Down, Ready for Operation

chlorine made possible the first efficient motor-truck-mounted, water-purification unit.

Experience had been gained by the Wallace & Tiernan Co. through co-operation with its British house in the construction of equipment for the British forces. Equipment based on the British unit was constructed and tested under varying conditions at Maplewood, N.J. Water was taken

from the west branch of the Rahway River, a grossly polluted stream.

This first unit was equipped with rotary pumps, which did not prove suitable, and subsequent units were equipped with gasoline-operated force pumps.

Various members of the American Water Works Association, who were officers in the Engineer Corps, or in the Sanitary Corps, offered helpful suggestions and contributions toward the development of this unit, which, when placed in operation, gave highly satisfactory results.

FIG. 4—LABORATORY, LOOKING TOWARD DRIVER'S SEAT

Separate water analytical laboratory trucks were contemplated, and it was ultimately concluded to modify the design to permit the incorporation of suitable laboratory equipment. By building a separate room in front of the truck, using small cylindrical tanks for contact and storage chambers, and placing these tanks under the laboratory benches, a marked saving in the space required was effected.

Description of Operation

The water is pumped through a 50 ft. suction line of 2-in. steel-woven suction hose, fitted with bronze check valve and strainer, by the gasoline-engine-operated pump located at the rear of the body. A very heavy dose of chlorine is applied in the pump suction, from a manually-operated solution-feed chlorinator located on the rear wall of the laboratory room. When waters of low alkalinity are treated, soda ash is applied with the chlorine solution.

Passing through the pump, with a relief valve set to operate at 50 lbs. pressure, the water is passed to a specially designed pressure filter, being treated en route with alum through the standard dash-pot arrangement.

From the filter, the water passes through a 1½-in. water meter, thence through a diaphragm pressure-regulating valve to maintain constant back pressure on the chlorinator water supply line, thence through the storage and contact tanks located beneath the laboratory benches, to the point of discharge at the forward left-hand corner of the truck. Just at the point of discharge, the water is treated with sodium thiosulphate solution, regulated and controlled by a special dechlorinating equipment.

These units were designed having in mind the grossly polluted and befouled waters that would have to be treated. Based on the British practice and experience, high doses of chlorine were introduced into the raw water. The filters served to clarify the water, and at the trial tests, absolutely sterile water was obtained at the point of discharge.

It was thought necessary to make provision for removing the excessive residual chlorine that would be in the water after passing through the contact tanks, and a proportional pressure-feeding thiosulphate dosing device was developed. It should be mentioned that provision for dechlorinating was made in accordance with the British experience, which used the process of dechlorination, by the application of compressed sulphur dioxide gas, in all portable units.

On the British truck, the sulphur dioxide was controlled by a standard direct-feed manually-controlled chlorinator of American manufacture. On the American truck, the chlorinator used was the standard manually-controlled solution-feed type.

Control valves for the soda ash and thiosulphate solutions were in the rear of the laboratory below the chlorinator, so that all chemical application could be centrally controlled by the laboratory operator.

The first several trucks were constructed with horizontal pumps, and it was found that special provision was required to eliminate excessive vibration in the laboratory. With this in view, special spring supports were developed. On the later trucks, a vertical force pump was used, and this

FIG. 6—LABORATORY, LOOKING TOWARD REAR OF TRUCK

so eliminated the vibration as to obviate the necessity of special spring supports.

The development, construction and testing of the first lot of trucks, and the tests and recommendations of the Board of Inspection officers representing the office of the Chief of Engineers, the Engineer Depot and the Sanitary Corps, resulted in many modifications of design and rearrangement of equipment, but not in any change in the basic principles involved.

The value of these units became so apparent that increased facilities were required for their manufacture. An

PROGRESSIVE METHOD OF ROAD IMPROVEMENT*

By Gabriel Henry
Chief Engineer, Department of Roads, Province of Quebec

In a country with a comparatively sparse population grouped in centres generally remote from one another, the general problem of road improvement is solved by means of two methods which may be used concurrently according to the amount of money available. On the one hand there is the method generally followed for main communication highways known as "trunk roads." This method is the normal one which is of the same nature as that followed in building railways, with the same complete preliminary studies and a similar organization for carrying out the work. On the other hand, there is what is called the "progressive method," which is better suited for rural road properly so-called. The object of this paper is to call attention to this second method, to describe it properly and make its advantages known.

The population of the province of Quebec is scattered over a very large area, generally in groups and living on long ranges sometimes remote from one another, from railways and from main highways, at distances which, in a densely populated country, would be considered very great.

The consequence of this is that every rural municipality has a very considerable length of roads under its charge. The average length of roads per municipality in this province probably exceeds 40 miles. Some townships have as much as 100, 150 and even 200 miles of roads under their control.

Roads in Agricultural Districts

Their population is chiefiy an agricultural one and naturally has not sufficient capital for improving such a long stretch, all the more so owing to the fact that, outside the St. Lawrence Valley, the country is generally undulating and sometimes broken; on the other hand, agriculture and trade have greatly developed within the past four years, and the need of connecting rural municipalities with one another, with railways and highways is becoming more and more felt. The use of automobiles is increasing even in the most remote districts. Requests for roads, on which at least automobiles can run, are becoming more and more insistent every day and the problem is becoming complicated from a domestic standpoint. How can all these requests be even partly satisfied? Such is the question answered by the second method.

Needless work must be avoided and as little as possible of work offering but transitory or short-lasting advantages should be done. All the work executed should be with a view to real, progressive definite improvement, and preference should be given to the work urgently needed. Thus, the works on rural roads may naturally be classified in two principal categories: Works of a permanent nature, and works of a non-permanent nature.

This distinction, as will be seen further on, is very important not only from the standpoint of the capital to be spent in making roads, but also from a technical point of view. It also naturally applies to road-making according to the first method. It must never be lost sight of.

Permanent Works

Permanent works comprise: Drainage, underdrainage; bridges and culverts; earthworks; special work, such as retaining walls, rip-rap, random rip-rap, etc.; work of minor importance, such as cobble gutters, small dry stone walls, earth basins, etc.; lastly, the foundation, which is one of the most important of permanent works.

All these works are called "permanent" because their duration must be unlimited and because the capital spent on them must be a life-long investment. For instance, reducing the slope of a hill from 15% to 5%, is a permanent work. Interest on the capital required for this work is and will always be represented by a lower cost per ton-mile as well as by reduction in the cost of maintaining the road, and the amount of interest will be all the greater as the traffic on the road increases.

As a rule, the cuts and fills for improving the profile of a road are permanent works. Deviating a road to get around a low-lying or wet spot, when drainage and underdrainage cannot be done and where no top course can be maintained except at a heavy cost; raising, by means of a fill, a road running through a low place in order to protect it from dampness and from flooding along a stream, are permanent works. All these works must be so arranged for that the capital to be spent on them will permanently yield good interest through the advantages they will procure.

Straightening is Frequently Profitable

The straightening of a road in order to decrease its length, is also a permanent work. If, for instance, one reduces by half a mile the length of a road four miles long on which a wearing course has to be put which will cost $10,000 per mile, the total cost of that top course will be lowered by $5,000. Such straightening may sometimes be effected for a smaller sum, including the purchase of the land required, while the expense of its maintenance will be reduced by one-eighth. The more expensive top courses are, the greater will be the advantage of reducing their length by well-arranged straightening.

Concrete bridges and culverts to replace wooden ones, may last indefinitely if they are solidly and carefully built, and the interest on the capital spent on them will be represented by a decrease in the cost of maintaining the road. Wooden bridges are comparatively costly to keep in order and require to be rebuilt from time to time. This cost of maintaining and remaking bridges is heavier, as a rule, than the interest on the cost of properly built concrete bridges.

Generally speaking, the works called "permanent" in connection with road-making, are the same as for railways, less the cost of purchasing, transportation and laying ties and rails. To sum up, their feature, as we have just said, is the effecting of a life-long investment and they must always be understood and executed so that the investment may be an advantageous one. These permanent works also possess the following important characteristics:—

Annual Maintenance Costs Decrease

If properly understood and carried out, the yearly cost of their maintenance will be greatly decreased. Such cost is practically independent of the volume of traffic. It is greater, as a rule, during the years immediately following their execution and it decreases gradually, as the years go by, to a certain fixed lower limit as the road settles down and nature establishes a new equilibrium in the place of that which was disturbed by the execution of the work. In good ground, the new equilibrium is very soon attained and the cost of maintenance rapidly drops to a trifle. But, in bad ground the cost, which may have been rather considerable at the outset and for some years, always ends by reaching its fixed limit.

The maintenance expenses of these permanent works consist chiefly in keeping the slopes in order, clearing the drainage system, repairing the drystone works and the foundations, for the latter often sink owing to uncontrollable changes in the regimen of the underground waters.

Such are the economic features of permanent works. Comparison with non-permanent works will bring them out still more clearly. From an economic standpoint, non-permanent works do not absolutely, constitute a permanent investment, but are rather a yearly expense. In industrial accountancy, they would be considered as more or less transitory investments and be classed among those represented by cost of equipment. Expenditure in connection with them would be classed partly among the items interest, renewals, depreciation, and in the list of fixed charges, and partly among the items of labor, supplies and repairs in the operating charges.

Contrary to the permanent works, the maintenance expenses in connection with them vary with the traffic volume and also with their age. They are almost nothing during

*Paper prepared for the last convention of the Canadian Good Roads Association. Included in association's report of proceedings (now on press) but not read because Mr. Henry was ill during the convention.

the first years after being done and progressively increase during a certain number of years, determined by the duration of their useful existence, which may, however, be lengthened by increasing the yearly cost of repairs and maintenance.

The non-permanent parts of the road consist almost entirely of what may be called "wearing-courses" or "top-courses" and correspond to the whole of the ties and rails in the case of railways.

As the wearing courses, which last for some time, are expensive as a rule, it can easily be seen that in the case of non-permanent works, the items of interest, renewals and depreciation in the fixed charges on the one hand, and those of labor, repairs and supplies in the operating charges, on the other hand, are comparatively high, and that consequently, the choice of top courses and their use is one of the most important problems in connection with road-making.

A Typical Problem

When we consider the general problem of improving the highways of a province or of a state, the pre-going remarks lead to the conclusion that in the case of roads, there is no drawback in doing permanent work progressively from year to year on roads, provided a well-defined plan has been adopted and is followed and that no work, or as little as possible of work, of a more or less temporary nature is done.

The following example will make this better understood:—Let us take a road 40 miles long which connects two important rural centres or makes a short cut between two main roads and runs, for instance, through five villages and a district exclusively inhabited by farmers and by settlers far from one another; a road which the population is really unable to maintain properly owing to difficuties in connection with the nature of the land and lack of money; which is impassable during a portion of the year and on which automobiles can hardly venture. Let us suppose that at present, in order to go from one centre to another, one must do so by rail or by a long round-about way and the five villages between the two centres are consequently isolated; that if this road was made at least passable, relations between the two centres and the villages would become more active, that the value of the properties along it and in the district generally would increase; and lastly, that this would greatly accommodate the travelling public in general, would promote the development of motoring as well as relations with the interior of the district and with neighboring districts.

Obstacles to be Overcome

On a length of six or seven miles this road is encumbered with large boulders, there is a hill with a 20% grade and two other long ones with a 15% grade all three being actually climbed with difficulty; there are also eight low-lying spots impassable in rainy weather. The bridges and culverts, mostly wooden, are in bad condition and even dangerous. In many places there are dangerous and soft springy spots and bad holes. The remainder of the road is nearly passable. There are field stones in the adjacent fields and good gravel banks here and there in its vicinity.

The chief obstacles to the opening of this road are the three hills, the rocks in the road, the low-lying spots and the soft springy spots. If only these defects were removed the road would become passable and automobiles could run over it.

The problem is this: Shall the road be built immediately at a great expense according to the normal method followed in the case of an entirely modern road with an improved wearing course, or shall capital be spent progressively and judiciously on the works of a permanent nature most urgently needed to open it at once to traffic?

By virtue of what has just been said, there is certainly no doubt that the second method is not only the most justifiable, but also the more advantageous, all the more so as there are many similar cases in the country to be considered, the carrying out of which according to the first method would necessitate the immediate investment of a considerable amount of capital.

It seems reasonable, therefore, first of all to improve the hills and to fill in the low-lying spots with the stones to be found in quantities in the neighboring fields. This filling can be done at first on a sufficient width of road to allow for vehicles passing over such spots without danger and the road may afterwards be widened as funds become available. The boulders should be removed from the road and the soft spots permanently cured.

All these works are permanent and the money spent on them will be a good investment, they will not cost much and in a short time in a single season the road might be made passable for automobiles. Improvements may be made, year by year, until the whole permanent portion of the work is finished, including even the foundation. A modern top course should be laid as soon as it becomes necessary, beginning at the villages where traffic concentrates, in the vicinity of the churches and shops. It is curious to note, even with a small investment in permanent works of this nature, roads can rapidly be made passable when the farmers themselves work at the improvements and furnish the stone which they remove from their fields.

This manner of proceeding is called the "progressive method." It progressively increases the value of the immoveable property of the country. The capital so spent is, or should be, as has been said, a good investment. This method must not, however, be followed to an exaggerated extent, for when a trunk road has to be built, traffic rapidly becomes so considerable that the laying of a regular wearing course becomes necessary at once and, in such cases, the normal method is the only justifiable and recommended one.

A full study of the various works above mentioned would take too much time under present circumstances. The following important remarks should, however, not be forgotten.

Complete Details Not Planned

When the progressive method is followed in improving a rural road, a complete study of the details and a general detailed plan with cross-section of all the road are not usually made beforehand. The details are studied only as need arises. Then it must not be forgotten that works which are not permanent or not of a sufficiently permanent nature must never be done and that all the capital spent on improvements must constitute a life-long and paying investment; and again that, in doing such works, they should be done so that it will never be necessary, when completing improvement work; to undo and do differently any works already done.

As rural roads are sometimes very winding and of irregular width, it is often difficult to obtain the land required for straightening them and equalizing their width. Consequently, when this method is followed in winding places of regular width, the axis of the road should be traced and given such a direction that it may, in each case, be prolonged in a straight line as far as possible, reserving enough land on either side between the ditches for the roadway proper and for suitable shouldering. The inequalities in the ditches and in the width of the shouldering may be attended to later on, but the roadway itself should be built in straight sections as long as possible. It is a permanent work which should not have to be begun over again later on. The straight sections should be connected by curves having as large a radius as possible. This radius should never be less than 300 ft. With such curves care should also be taken to raise the outside of the road higher than the inside before laying the foundation.

Heavy and Light Work

In this method as in the normal method, earth work is divided into heavy and light work, but with a difference. As in the normal method, heavy earth work consists of large fills and cuts of which a special and complete preliminary survey, with plans and cross-sections must be made. Such work must be staked out separately, but may be performed in sections at different times as funds becomes available. In this method, light earth work usually comprises light grading, cleaning ditches, etc., outside of sections staked out for heavy earthwork. In these sections no heavy work is to be carried on. Such sections are also separately staked out. Light grading may be largely performed by means of the road machine, and is generally carried out without a special preliminary and complete survey but under the superintendence of a competent foreman accustomed to such work. In

this method, heavy earth work is reckoned by the cubic yard, light work by the mile. It must be added that road lengths requiring heavy earth work represent as a rule only a small proportion of the total length.

Cutting Down Grades

It is useless to reduce gentle slopes but it should not be forgotten that a road with a very wavy longitudinal profile is most disagreeable. Hence all the slight undulations in the road should be machine levelled so that the slopes may everywhere be gentle and regular and their length nowhere be less than from 150 to 200 ft.

If 5% be the maximum limit allowed for grades of steep hills, it is useless to reduce slopes of less than 5%, unless they are too close and form narrow ravines, in which case it is better to reduce to 3 or 4%, and sometimes less.

In the method of progressive improvement, it is better where there is no heavy earth work to do, and whenever possible, to proceed by successive thin layers which are beaten down by traffic one after the other and cause less obstruction. When too much digging is done at the same time and too deep layers of earth are spread on the surface of a road, the latter usually becomes impassable in rainy weather and dragging is more costly.

No road can be kept in good order if its substructure is damp. No wearing course, however costly it may be, can last on an insufficiently drained substructure. It is needless to insist on this universally admitted fact. Drying and draining the road are difficult undertakings and call for much experience, judgment and time.

Drainage and Underdrainage

To dry and drain a road there are two requisites: First, to drain off rain and melted ice and snow as rapidly and completely as possible; second, to dispose of the dampness which the subsoil always contains.

The surface waters are discharged; subsoil moisture is removed by underdrainage. *Drainage* and *underdrainage* are the two essential requisites for starting road improvement. They must be undertaken beforehand because a real and sufficient solidifying of the substructure through underdrainage often cannot be obtained in our climate before several months and sometimes a whole year and even more. Drainage is obtained by means of a complete system of ditches, gutters, culverts and bridges.

Ditches should not be dug or maintained where they are not absolutely needed. Of the permanent road works, ditches are the most expensive to maintain and their length should be reduced as much as possible. They should also be made as shallow as possible. Deep ditches, besides being expensive to keep up, are very dangerous. Deep ditches are often supposed to dry the body of a road. It is not always the case; in this climate, it is so only in soils which easily part with their moisture.

Construction of Ditches

Permanent ditches should be as straight as possible. Winding ditches are more exposed to erosion by water and consequently cost more to keep up. The longitudinal slope of ditches should not be less than five inches per hundred feet when it is possible without too much expense. Nor should the slope be too considerable, on account of erosion. Naturally in more resistant soil it may be more pronounced. They should empty rapidly and completely after rain and retain no stagnant water at any place. Their side slopes should not be over 45 degrees. When the latter are steep, they should be strengthened by means of dry stone walls or rip-rap, at least up to a certain height. Where the slope is pronounced and the land non-resistant, the bed should be paved to prevent erosion, and the curves reinforced by dry stone walls. The gutters should be the continuation of the shoulders and no stagnant water should remain in them anywhere in hollows. The outlets in which the ditches empty should be put in order and be large enough easily to carry off all the water they receive under the heaviest rains.

To sum up, the ditches, gutters, culverts, bridges and outlets all together should form a system capable of draining completely and as rapidly as possible and without erosion anywhere, the water from the heaviest rains and spring thaws, leaving no stagnant water in hollows.

In the subsoil there is nearly always a sheet of subterranean water at a certain depth. The depth at which it is met with varies greatly from one point to another. It varies also with the seasons and diminishes in the spring. In many places, the level of this sheet of water is almost flush with the soil and when the spring thaws occur it rises even above the soil. On the other hand, there are soils in which the water easily rises by capillarity, and also soils which hold fast water absorbed by them. When the sheet of water is at a small depth and the ground covering it of the former nature, the water may rise by capillarity to the level of the soil. The air circulating at the surface of the soil evaporates this water and there is thus established a kind of vertical current between the sheet of water and the surface. Though the surface appears dry, the subsoil is moist and soft. If the surface is covered with an impervious wearing course, the action of the air is no longer felt, the water continues to rise until the soil is saturated and the earth becomes still softer.

The Plague of Roads

In cold weather all these moist earths easily freeze to a great depth and then swell. When earth freezes water is attracted, as it were, by the ice crystals forming everywhere, especially at the surface. In the process of freezing land can absorb much more water near the surface and hold it in the shape of ice than it could absorb and hold under ordinary temperature conditions. Thawing begins at the surface. As the water cannot escape through the subsoil which is still frozen, or clayey, stony or of some other impervious substance, it gathers, producing "soft spring spots" on a foundation of ice, clay, rock or generally impervious substance.

These spots, called by the farmers "ventre de beoufs," are truly the plague of roads in this latitude. They are to be found everywhere. They occur every year at the same places, making roads dangerous until the end of June. They even occur on improved roads at places where they did not previously exist. All earth should, therefore, be freed as completely as possible from subterranean moisture before a road becomes sufficiently resistant.

V-Drains and Cobbled Trenches

Work, whose object is to free the soil from subterranean water and drain it, is called underdrainage. This underdrainage is done by means either of earthen or concrete pipes or of field stones. The object is to prevent water from rising in the soil by capillarity to less than 18 ins. beneath the bottom of the foundation.

Drain pipes should be used only when springs are met with or when the surface of the subterannean water rises at times or remains continually at a small depth beneath the surface of the soil. This is ascertained by digging small wells to a depth of about 4 ft. If at the end of 24 hours, for instance, water is found there, the surface of this water marks the level of the subterannean sheet of water, and pipes should then be used. If no water appears and the earth is still moist and soft, it is the case previously mentioned of land absorbing and holding humidity. In such lands, which frequently contain soft, springy spots, pipes have little or no effect. Other means must be used. Generally, field stones are disposed in thick layers, serving at the same time as foundation, made in the shape of a V to economize stone and to drain the water, or else trenches filled with cobble stones are used. V-drains are frequently expensive on account of the large quantity of stones required. Drains made of trenches filled with cobble stones, when they are judiciously used, well laid and proportioned, give as good results in the long run and are less expensive.

Obviously, drying and underdraining the subsoil, while indispensable, are not always an easy task, and it may be said again that suitable results take much time to achieve unless the cost is increased in order to obtain a quick result. However, it is drainage and underdrainage that should be first carried out in order to allow the soil to dry and settle

before laying the wearing courses. The modern top courses are generally expensive, and it is neither recommended, nor even justifiable, to risk them when the substructure is not sufficiently dry or firm, even though there is a good foundation.

The progressive method of improving roads gives all the time necessary for a proper preparation of the substructures, and traffic hardens them. When the time comes for laying the foundations and top courses, the firmness of the soil on which they are to be laid is accurately known. It must always be borne in mind that undulations in the wearing courses which appear after a few years, are nearly always due to lack of firmness in the substructure, whatever the resistance of the foundations and the quality of the materials may be. Undulating surfaces with many depressions will be found even in wooden pavements resting on concrete foundations, due to the above cause.

Foundation Problems

The foundation is one of the most important things in road-making. Its object, as everybody knows, is to distribute wheel pressure over a sufficient surface of the structure so that the latter, and consequently the wearing course, will not be sunk or perforated by the wheels. It constitutes a resistant protective cushion between the wearing course and the soil. Foundations are classed among the permanent works because they have all the above-mentioned characteristics of such works.

In laying foundations it must always be borne in mind that a permanent work is being done, and care should be taken to make it a durable one. Vehicle wheels must never reach them, and they must be thick and solid enough to prevent their being broken or crushed out of shape by the heaviest vehicles. This, unfortuntely, has not always been understood, and there have been many disappointments, especially since heavy trucks have come into use. At present this is better known and is receiving more attention.

Foundations are made of concrete, stone, boulders or gravel, and even of sand when the soil is clayey. Without entering into the details of their construction, it is nevertheless useful to call attention to the following points of importance: Homogeneity and hygroscopicity. When stones of different sizes are used in making the foundations, the different sizes must be laid one upon the other in uniform layers, and they must not be made throughout their whole thickness of stones of the same size in one place and of another size in an adjacent place. Too much gravel, dust or sand must not be used at one place to fill voids and a smaller quantity in another location.

Materials of Uniform Size

The best foundations are those made of uniform size throughout all their thickness and laid in a uniform manner. When stones from four to six inches in size are used, they must be of good quality, pressed solidly against one another by hard rolling so as to break the excessively thin corners and edges and to interlock them firmly. If the stones are unstable, too soft or alterable, the vibration caused by passing vehicles will wear them out at the points of contact, and, in the long run, the foundation will sink irregularly.

The stones must touch each other, and filling the voids with too much dust, sand or even gravel is another drawback, as the stones then will not touch; and in such a case the firmer particles have a tendency to drop and the larger pieces of stones to rise, at least in this climate, causing, in the long run, harmful movements and some kind of segregation in the foundation.

Foundations of coarse sand, not hygroscopic, where laid on clay soil, give good results under water-bound macadam, and are economical in places where stone is dear. Well-made Telford foundations are excellent, but very expensive.

The concrete foundations are the best, but their cost is generally considered too high in the case of rural roads. They are subject to cracks in soil not dry or firm enough, especially on account of frost, and it frequently happens that the cracks rise to the top course.

In calculating the thickness of foundations, it is absolutely necessary to take the heavy weight of modern motor trucks into account.

Temporary Gravel Roads

When the regular wearing course is laid, their solidity and lowed, foundations may be laid long before the regular wearing courses, and may, if covered with a layer of gravel, be used as gravel roads until a regular top course becomes necessary owing to increased traffic. During the interval, the roads are kept as gravel roads, and arrangements are made so that, when the regular wearing course is laid, it will not be necessary to scarify them or do any other work over again. Following the same method, the foundation may also be made wholly of gravel covered with an additional layer of gravel, and used as a gravel road till a regular top course becomes indispensable.

The temporary use of foundations covered with gravel as a wearing course allows of regular compacting by the traffic and of correcting their defects whenever they appear. When the regular wearing course is laid, their solidity and resistance are exactly known. The soft places have become hardened, and there is less likelihood of the defects which occur in wearing courses laid on an insufficiently firm foundation.

I may add also that, in this province, the rural roads are covered with snow during a portion of the year, and, consequently, the wearing of the top courses of the rural roads by traffic is much less than in countries where there is traffic throughout the year, and this may have much influence on their choice.

It would be advisable also to consider substituting one kind of top course for another, taking existing conditions in this province into account; also to consider what precautions should be adopted when laying cheap temporary top courses for avoiding certain expenses which otherwise would be incurred when it becomes necessary, owing to increase of traffic, to use them later on as foundations and to cover them by improved top courses.

Senator G. D. Robertson, Minister of Labor, has notified D. K. Trotter, secretary of the Association of Montreal Building and Construction Industries, that the association will be invited to select its own delegates to the National Industrial Conference to be held Thursday, September 11th, in Ottawa.

The annual convention of the Associated Boards of Trade of Vancouver Island was held July 10th in Courtenay, B.C. The principal proposals endorsed were the extension of the Esquimalt & Nanaimo Railway to the northern end of the island, the construction of about twenty-two miles of road to open the Sayward district for settlement, and the continuation of the Strathcona Park road.

"Town planning in Great Britain," says "Conservation," "has so far advanced beyond the experimental stage that it has now been decided to make it compulsory for every town, having 20,000 inhabitants or more, to submit a town planning scheme for its own area to the Local Government Board, not later than 1926. The British people realize that haphazard growth of towns leads to serious evils and they are determined to control it. In future, land will have to be developed so as best to serve the interests of the community, which, in the long run, is usually in the interests of the landholders themselves. Only the land speculator is adversely affected. If the public wish to put that individual out of business, they cannot do it more effectively than by actively promoting proper schemes of town planning. In Canada, the province of Nova Scotia took the lead in making town planning compulsory in 1915. The only other province which has a compulsory Act is Saskatchewan. These are therefore the only two provinces abreast of the Old Country in town-planning progress, though most of our provinces have enabling Acts in force."

COLLECTION AND DISPOSAL OF REFUSE IN THE FUTURE*

By F. W. Brookman
Cleansing Superintendent, Rochdale, England

GENERALLY speaking, refuse collection resolves itself into transport and loading strength; and transport may be petrol, steam or electric, or horse-drawn vehicles.

Petrol wagons, in spite of the cost and difficulty in obtaining petrol, have been a great help during the war, and I want to suggest that as the cost of the wagons gets easier and the petrol becomes more plentiful, the home-manufactured benzol should be used either alone or mixed with petrol, for several reasons. First, it is an English product, and before the war was less in price than petrol, while 15% more power can be got out of the gallon. It is a saving in shipping also, and for some years to come we shall have none too many ships to carry the trade of the country, to say nothing about buying petrol abroad when we have a good home-made article. For all users of petrol vehicles it would be a good thing if there were inspectors on the road to send home all badly-running vehicles, and if the wagon was taken in hand at the first warning there would be many less breakages.

While many of the petrol wagons were commandeered early in the war, the better type of steam wagon seemed to disappear entirely, and thus municipalities had not the same chance with these as with the petrol wagons. The fact that they were extensively used in France and elsewhere on road-making and repair, points to their use after the war for the heavier classes of work, and where transport schemes are being fixed up, they will no doubt be much used for the heavier traffic such as road materials, coal, etc.

The Choice of Wagons

It is not always easy to decide what size of wagon is the best to adopt, but where its work is more or less of a certain type, or, shall we say, suppose a wagon is to work nine-tenths of its time on one job, naturally that job should rule the size, and it should always be remembered that a 6-ton wagon costs no more in labor to run than a 4-ton does, and there is less time taken per ton at each end of the journey getting into position and also in loading and unloading.

The electric wagon has been much to the fore during the war, and could they have been obtained there is no doubt that they would have been in evidence almost everywhere. Where they have been adopted for comparatively level work I have heard them well spoken of, but in cases where the roads are other than level this has not always been the case. This does not by any means condemn the electric wagon, but only shows that sufficient care has not been exercised in purchasing the wagon, or that the makers may have been so eager to sell that they have sold a less power wagon than was warranted for the work in view, and that both buyer and seller be to blame. Of course, this also obtains with petrol wagons, and a wagon is purchased for 30 cwt. load and often works to 2 tons and trouble soon results. To my mind the electric wagon is a most economical wagon to run if of a sufficiently powerful type without it being necessary to undermine its constitution by want of energy.

Horse Transport

We now come to our old friend and servant the horse. Owing to the high price of horses and provender it is now a question as to just where the dividing line should come in. This must depend on the district, for in one case it may pay better to work a horse in a four-wheeler as far out as a mile, while in another case half a mile might be over the mark. Now that the 48 hours is the limit, the horse journeys may be so shortened that the old number of journeys can be done, and the quicker-moving motor wagons put on all outside the horse area. In this outside area you can use either a moderately-sized wagon or a wagon about half the size and holding about the same as a horse four-wheeler. Suppose, however, you put on a large wagon and put all the men on it that you would put on to three small ones, your result would be nothing like the same. You might possibly not get done more than half what the three small wagons would do because of the distance the large wagon would have to travel to get a load, and the unwieldy character of the machine in small areas.

Tipping and Loading

As to tipping wagons, the tipping arrangements should be of the simplest possible character. The experiment has been repeatedly tried on two wagons—one a tipper and the other a non-tipper—of moving the same material from and to the same place, and the non-tpper could easily beat the tipper owing to the character of the tipping arrangements.

Whenever possible the vehicle should be such as to be readily loaded by a man on the pavement without the use of a ladder. Wagons of the type used at Bury are easily loaded and tipped, and it is not difficult to get comparatively low-bodied wagons of other types to fill this requirement, and recently I have seen steam wagons that could easily be loaded over the side and at the same time give a passable tip. These wagons will carry up to 5 tons in weight and run well on coke breeze, with which a cleansing department could easily supply itself from the refuse.

The matter of the blowing about of dust, etc., by the wind during the operation of loading is very important, not only from the annoyance caused to people in the vicinity, but also from the fact that this dust once adrift never ceases (as long as the wind lasts) to annoy someone, and even the street-sweeping machine helps to make the nuisance worse, unless it is of the sprinkler type and thus brings the dust to rest.

It is not easy to find a complete cure without disadvantages. There are carts and wagons elaborately covered in and having side or flap doors through which to pass the refuse. There are vans with bodies partly covered over with a permanent hood, and from the end of this hood an ordinary sheet covers the remainder. There are wagons and carts with lorry poles down the centre, supported by iron hoops, something like a grocer's lorry with rain-sheet spread; and there is the loose cart or wagon sheet tied down at the front end on to the cart, wagon or lorry, and unrolled as it is required to cover the refuse and tied down so far each time in sections as the load is completed. These are all more or less satisfactory, and in some places more than others, for in some towns strong winds are much more prevalent than in others. The disadvantage is that the loading, etc., cannot be so easily watched or checked as with open vehicles. The wear and tear with permanent covered vehicles is considerable, and the additional weight is a great consideration, particularly in hilly towns, which, as a rule, are also those towns with more than their share of wind. It has been suggested that ash bins should be taken to the depot and there emptied, which, while being the ideal method, I am afraid will not appeal to us at this time of high prices, for by working in this way every load would be as great a weight of bins as of bin contents, and this is absolutely out of consideration. Further, to work in this way the municipality would have to own and supply all the bins and keep them in repair. I fear we are not yet in a position to do this.

I take it, then, that it is up to each authority—and, of course, every official—to decide what alterations they can make in methods of collection, and particularly think out the problem as to which is best adapted to their respective district, because it does not follow that the electric wagon will be best for Halifax or Bradford just because it does well for Southport or Blackpool.

Position of Ash Bins

In connection with refuse collection, another point requires constant attention in the future. In many districts now a wagon could be loaded in half the time at least, if the ash bin or ash place were accessible from the passage without having to go the length of the garden or yard, not to mention locked yards. I thing the position of the ash bin is an important item on a building plan, and that it should be

*From a paper read at the annual conference of the Institute of Cleansing Superintendents, England.

put in the most accessible position. In the case of old property it would be time well spent in many cases when any alterations or repairs are being executed, whether to the ash-places or not, to talk the matter over with the landlord and point out to him not only the advantages that an alteration in the site of the ashplace or bin would be to us, but also how such an alteration would benefit him and his tenants. It is no uncommon thing for a load in one particular district to take as long as two loads in a better arranged part of the town.

Another point that tends to waste time is where dwellings have their own particular utensils for containing ashes and refuse, in which case every particular bin or tub has to be carried back again after being emptied into the cart or wagon. In some cases the refuse must be carried from the back round the end of the house to the front and the length of the front garden or lawn into the front street. These are the places that waste time, get the men out of sight, and cause trouble all round.

Sometimes we do see something quite contrary to the time-wasting process above mentioned, and I shall never forget a little performance I once saw in the collection of refuse.

I had appeared on the scene quite without notice, and in the absence of the local superintendent. The ash bins (all galvanized) were previously deposited along the kerb-stone edge by the tenants, and while the motor wagon travelled up the centre of the street the ashmen simply hoisted up the bins onto the wagon (without it stopping) and the man in the wagon picked up the empty bin and dropped it over the side into the hands of the man who brought it. I thought that was ideal refuse picking up. Unfortunately, ninety-nine towns out of the hundred have not the authority to order the tenants' ash-bin to parade at the kerb-stone. I suppose there is often a fly found in the ointment, and while in the case cited I did not find it, in some cases where the "kerb-stone parade" is in vogue, an awful mess is made in the street by rag-pickers and others pulling the stuff over.

Special Collections

Prior to the war in many towns there were special collections (besides the refuse and nightsoil or excreta) of waste fish and butchers' offal, infectious fever pails, fruiterers' refuse, etc., and during the war others have been added such as paper, leather trimmings, broken food, rubber, potato peelings, etc. As to how many of these will fall out again, only time will demonstrate. While in some cases it was necessary to use every effort to obtain certain materials irrespective of cost during the war, it is quite certain in some cases that such effort is not being maintained, and time only will demonstrate how many of the above will lapse. One thing is certain, with the present price of labor even municipalities cannot be expected to pick out and collect materials which are difficult to dispose of and at the same time do not pay for the handling; for while such collections were very necessary during the war, the end of that catastrophe ends the necessity.

Disposal of Refuse

Having collected the town's refuse, we must dispose of it in some way.

I want you to realize the fact that if you have anything at all you can make into a decent manure, it is up to you to do it, and I do not think you are likely to create a glut in the market in that direction.

In a few towns the pail contents are dried and thus made into a valuable manure, for the mere act of drying (along with a little acid) can under certain conditions increase the percentage of ammonia up to 12%, which makes it work out about half as much as sulphate of ammonia for this item alone, and there are also present certain phosphates, potash, etc., so that it is a good all-round manure. The production will continue until the pails are replaced by water carriage, when we shall look to the sewage works to have produced a good substitute, and they will have no little problem in that the town manure will be intermixed and partly dissolved in millions of gallons of water.

With reference to the ash refuse we are not much nearer a good solution. In pre-war times it was almost the unanimous opinion that the refuse should be burnt so as to get rid of the putrefactive or organic matter and to make an innocuous clinker that could be used for many purposes, or tipped anywhere without being detrimental to health. While the matter of cost was at the time fairly heavy, both in collection and burning, it was low compared to what it is now. Given that we shall eventually exterminate the pail closet, there is no chance of eliminating the ashes collection, for while it is possible in certain factories and manufacturing premises to establish suction conduits to carry off the dust, sawdust, shavings, shoddy, etc., it would be quite a different problem to instal a system to draw away to the depot or the tip the ashes refuse of a town, intermingled with the pots and pans, tins, broken bricks, etc.

Screening and Washing Plants

Recently there have been put down screening and washing plants for screening out of the refuse the cinders and washing them so as to recover this valuable fuel. This, of course, separates out the inert fine ash—a material in itself which cannot be burnt, and which acts as a drag on the burning of the better fuel. Further, this is taken out at the first handling, and thus is not left either to be matted up against the clinker in the destructor and afterwards laboriously withdrawn and deposited on the clinker bank, or to be as laboriously riddled through the destructor grate if the stoker is sufficiently energetic so to dispose of it. In my opinion the screening of the refuse is a much better proposition than grinding up the whole of the material, good and bad, for it does enable you to use the good fuel, which, in its turn, may be used as fine ashes later. As I previously mentioned, the inert fine ash is thus eliminated from the good fuel, which is then washed to dispose of adherent damp ash, etc. Where the fuel is to be used for steam raising (or like purposes) on the premises, the washing may be dispensed with and the plant simplified; but this must, of course, be left to local requirements. In some particular cases it may suit the conditions to get all the fine ashes possible, but I wish to point out that the material that will not pass through a $\frac{1}{4}$-in. screen is not the same class as that which will go through it; and even if you grind it the composition remains what it was before, and unless you want the material purely as an absorbent or as a mechanical lightener of clay land, you may have had your labor for nothing. Supposing, however, you ground the clinker to a fine powder, you would render the lime contained in it available for agricultural purposes, and (depending upon the kind of coal used in a particular district) it would act on the land in exactly the same way as the lime in sewage sludge does, but it would save the carriage of the water in the latter and be much easier to spread and to work in. The availability of the lime for this purpose would depend upon its fine grinding, just as it will be remembered the now much-valued basic slag many years ago failed for want of proper milling. In that case the Germans bought all the production, and we have not yet fully recovered; but the war has set the material at liberty again.

In the past many novelties have been tried in the shape of moving and rocking grates, high blasts and low ones, fan and steam blasts, etc., for our furnaces. Top feeds, back feeds and feeds in front, by hand and machine, sloping and flat grates and furnaces without grates at all; many fairly successful, other failures, and still we have not the ideal furnace into which the loads can be tipped in bulk, and while everything combustible is consumed, what is not consumed is melted and comes away from the furnace (without laborious clinkering operations) in the fluid condition. Attempts have been made in this direction, but as yet without success, owing largely to the refractory nature of a very small percentage of the whole, acting as a block to the operations. I feel sure that eventually this will be overcome; but while the necessity for screening refuse might then cease, the average percentage of the clinker produced is not likely to be below 33%, in spite of the assurance of some years ago that two-thirds of ordinary destructor clinker could be easily consumed.

RIVETED JOINTS FOR STEEL PENSTOCKS AND TANKS

(Continued from page 200)

In Table 6, for ¾-in. plate the thickness of butt strap is given as ½ in. In Table 8, the minimum rivet diameter for ¾-in. plate is ⅞ in., and the maximum for ½-in. plate is 1⅜ ins.

First trial: Assume 1⅛ ins. diameter rivet and a long pitch of 16⅜ ins. Then

$t = 0.75$ in. $c = 95{,}000$ lbs. per sq. in.
$P = 16\frac{3}{8}$ ins. $= 16.375$ ins. $s = 44{,}000$ lbs. per sq. in.
$d = 1\frac{3}{16}$ ins. $= 1.1875$ ins. $S = 88{,}000$ lbs. per sq. in.
$a = 1.1075$ sq. ins. $b = \frac{1}{2}$ in. $= 0.5$ in.
$f = 55{,}000$ lbs. per sq. in.

$A = Ptf = 16.375 \times 0.75 \times 55{,}000 = 675{,}469.$

$B = (P-d)tf$
$= (16.375-1.1875) \times 0.75 \times 55{,}000 = 626{,}484.$

$C = NSa+nsa$
$= (8 \times 88{,}000 \times 1.1075) + (3 \times 44{,}000 \times 1.1075) = 925{,}870.$

$D = (P-2d)tf+nsa$
$= [(16.375-2 \times 1.1875) \times 0.75 \times 55{,}000] + (3 \times 44{,}000 \times 1.1075) = 723{,}690.$

$E = (P-2d)tf+dbc$
$= [(16.375-2 \times 1.1875) \times 0.75 \times 55{,}000] + (1.1075 \times 0.5 \times 95{,}000) = 630.114.$

$F = Ndtc+ndbc$
$= (8 \times 1.1875 \times 0.75 \times 95{,}000) + (3 \times 1.1875 \times 0.5 \times 95{,}000) = 846{,}094.$

$G = Ndtc+nsa$
$= (8 \times 1.1875 \times 0.75 \times 95{,}000) + (3 \times 44{,}000 \times 1.1075) = 823{,}065.$

$H = (P-4d)tf+nsa$
$= [(16.375-4 \times 1.1875) \times 0.75 \times 55{,}000] + (3 \times 44{,}000 \times 1.1075) = 625{,}721.$

$I = (P-4d)tf+ndbc$
$= [(16.375-4 \times 1.1875) \times 0.75 \times 55{,}000] + (3 \times 1.1875 \times 0.5 \times 95{,}000) = 648{,}756.$

$e = H/A = 0.926 = 92.6\%.$

Maintaining the same diameter of rivet, a long pitch of 16½ ins. gives an efficiency of 92.7%. The short pitch in this case is 4⅛ ins., which is approaching closely to the maximum limit for caulking that should be used.

Using 1⅜-in. diameter rivets, the maximum permissible pitch may be increased above that for 1⅛-in. rivets by 1½ times the change in rivet diameter, making $P = 18$ ins., for which the efficiency is 92%.

To obtain an efficiency of 92.7% with 1⅜-in. diameter rivets, a long pitch of 19¾ ins. is necessary. Since this exceeds the 18-in. limit, it cannot be used; therefore the proper joint is obtained by using 1⅛-in. diameter rivets with a long pitch of 16½ ins.

To find the necessary thickness of butt strap,

$b = [P/2(P-nd)]te.$
$= [16.5/2(16.5-4 \times 1.1875)] \times 0.75 \times 0.927.$
$= 0.489$ in.

Therefore, butt straps ½ in. thick, as given in Table 6, are sufficient.

PUBLICATIONS RECEIVED

MANUFACTURE OF MUNITIONS IN CANADA.—Presidential address of H. H. Vaughan at the last annual meeting of the Engineering Institute of Canada. 92 pages and cover, 6 by 9 ins., illustrated.

TESTING OF ANEROID BAROMETERS.—Bulletin 42 issued by the Topographical Surveys Branch of the Department of the Interior, Ottawa, describing the testing of aneroid barometers at the laboratory of the Dominion Lands Surveys, and commenting briefly on the errors of aneroids and their general characteristics.

D. H. McDougall, president of the Nova Scotia Steel & Coal Co., Ltd., has completed, for his company, the purchase from the British Ministry of Shipping, represented by Director J. B. Whyte, of New York, of the coal-handling plant at the Canadian National Railway terminals, Halifax.

WATER PURIFICATION UNITS MOUNTED ON MOTOR TRUCKS

(Continued from page 202)

admirable factory in Camden, N.J., was obtained, and here, in conjunction with our construction work, a school was conducted for Sanitary Corps men, members of the water-tank train, and officers who were to have charge of the trucks in operation.

Fig. 2 shows the units as finally developed, closed and ready for the road, and the detailed arrangement is indicated by Figs. 1, 3, 4 and 6.

Fig. 3 shows the rear of the completed truck, with the rear and side gates let down for operation. The gasoline storage tank is to the right of the pump. The provisions made for carrying and chaining the suction hose are shown.

The filter, central control valve for operation of the filter, soda ash solution tank, alum pot, dechlorinator and further details of the pumping room are shown in Fig. 1.

Arrangement of Apparatus

In the upper right hand corner of Fig. 1 may be seen a tool box in which a complete set of pipe cutting and fitting tools are kept, in addition to hand tools needed about a machine shop, and beneath this tool case, is the chemical bin for storage of alum, soda ash and thiosulphate.

The laboratory arrangement in the final truck is shown in Figs. 4 and 6. The provision made for carrying chemical bottles is indicated, as is also the sink for washing glassware, and a hand air-pump for creating pressure in the storage tanks when the pumping equipment is not in operation. A 37 deg. incubator for bacteriological samples, oven for sterilizing glassware and electric lighting equipment are shown, while in the rear of the laboratory is seen a standard solution-feed chlorinator, and beneath it, the thiosulphate and soda ash controls. On the bench beside the chlorinator is a pressure auto clave for sterilizing purposes.

The first several trucks were mounted on 3½-ton White truck chassis, but by far the largest number were mounted on 5-ton, 17 ft.-wheel-base Pierce-Arrow chassis. Novo 8 h.p. gasoline engines were used, with Gould 5 by 5-in. force pumps. The filter was constructed by the Roberts Filter Mfg. Co., of Darby, Philadelphia, Pa., and the electric lighting equipment by the Vesta Storage Battery Co. The rated capacity of the unit was 1,000 gals. per hr., although the actual delivery was nearer 1,500 gals.

The support of the filter, which weighed 2,400 lbs. without the water, presented problems that required careful study. The final solution was to fasten 5-in. steel H-beams to the chassis frame by U-bolts, bolting the filter to the H-beams by feet cast on the special filter base.

Over Thousand Articles Carried

In addition to the equipment shown in Figs. 1 and 3, 1,031 articles were carried; still, much to our dismay, when the trucks were first placed in operation, we found that we had overlooked the very obvious item of a box of matches!

These units rendered valuable service under actual military operation in France. Some of them were damaged by shell-fire and some members of the Sanitary Corps were wounded while operating the units near the firing line.

Acknowledgement must be made of our appreciation of the co-operation extended by the surgeon-general's office, the Sanitary Corps, the Engineer Depot, and particularly to the following officers:—Col. F. F. Longley, Lt.-Col. Edward Bartow, Major H. McC. Yost, Capt. Morris Scharff, Capt. Gerald W. Knight, Capt. W. F. Wells, Capt. J. J. Newman, Lt. A. H. Wagner, Lt. H. H. Scott and Lt. T. W. Smith.

Without the suggestions and co-operation of M. F. Tiernan, and C. F. Wallace, of our organization, these units could not have been constructed, and special thanks are due to two members of our staff until recently in service in France, Capt. A. R. Murphy, who materially contributed to the development of the first unit in the tests at Maplewood, N.J., and Capt. R. V. Donnelly, who was in charge of their construction at Camden, N.J. Thanks are also due to the engineers of the Roberts Filter Mfg. Co. for their special co-operation.

RIVETED JOINTS FOR PENSTOCKS

IN many of the more recent hydro-electric developments of large capacity, it has been necessary to use steel penstocks of large diameters under high heads, and in order to keep the thickness of metal within reasonable limits, so that the work can be handled by the ordinary equipment of structural shops, it is quite essential to use the most efficient types of joints.

The article by H. A. Babcock and J. R. Montague in this issue assembles information on the design of these heavier joints which is not readily obtained in text books, and which should, therefore, be of value to designers who have to handle problems of the nature discussed.

The strength of a joint depends upon three main factors, namely, tension in the plate, shear on the rivets and bearing on the rivets; and as in the heavier types of joints one finds several combinations of these three factors, these *combinations* must be carefully considered when solving for the maximum efficiency.

CONTRACT FORMS

CONTRACT forms and specifications have been the subject of special study by engineers and architects for a number of years. The American Institute of Architects has developed the Standard Documents; the American Railway Engineering Association has adopted a uniform general contract form; a special committee of the American Society of Civil Engineers has the subject now under consideration. To date, the only voice which the general contractor, who is the man most vitally interested in contract forms, has had in the matter, has been either on the invitation of some one of the committees of these associations, as an ineffectual protester in some local exchanges, or as the victim of circumstances on an individual contract. What he has said before the committees of engineers and architects has doubtless had some effect on the final results, and at least has put the contractor's position on file. What he has said in his local exchange or in the secluded recesses of his own office, will doubtless never be allowed publication. Both the Association of Canadian Building and Construction Industries and the Associated General Contractors of America now propose to make the general contractor's position clear and effective on the subject of contracts. They intend to make a careful study of existing forms, both good and bad, of every kind, and in co-operation with the engineers and the architects, to eliminate unfair practices and to establish clear, definite and equitable clauses in contracts under which general contractors of recognized standing will work.

OWEN SOUND'S INTERSWITCHING PROBLEM

OWEN SOUND lies in the valley of, and at the mouth of, the Sydenham River. The harbor was formed by widening and deepening the river. The mouth of the river at the entrance has a width of 295 ft.; the main harbor has an average width of 350 ft. The upper or narrow portion, near the Tenth Street bridge, is only about 100 ft. wide. The town is served by branches of the Canadian Pacific and Grand Trunk railways. The yards and stations of each immediately adjoin the harbor, the Grand Trunk being on the west and the Canadian Pacific on the east. There is no connection between them. Each railway enters the town through an industrial district which it well serves. Neither road, in any place, traverses a residential or business district or crosses an important street. The station of each is within about one-half mile of the business centre of the town. But there is no connection between the two railways, thus preventing the interswitching of either passenger or freight cars.

A number of methods of interswitching have been proposed, and W. F. Tye, consulting engineer, Montreal, was recently asked to investigate them. Mr. Tye has reported that the best method, from a strictly railway point of view, would be to permit the Grand Trunk to follow First Avenue West to a point between Ninth and Tenth Streets, cross the Sydenham River at the bend, switch back at a point on First Avenue East just south of Ninth Street, and run back to the Canadian Pacific Railway on First Avenue East. "As such a route would be highly objectionable to the residents of First Avenue West," says Mr. Tye, "I did not seriously consider it."

Of the other suggestions, he reports that only three appeared to be worthy of detailed examination:—

1.—Crossing the river at its mouth.

2.—Crossing the harbor at Tenth Street traffic bridge and switching back on First Avenue East.

3.—Electrical switching.

Of these three Mr. Tye recommends the second method despite the fact that it would bring steam locomotives into the mercantile districts, passing and shunting directly behind a number of the best shops, with all the attendant disadvantage of noise, soot, dirt, smoke, etc. They would also pass within 300 ft. of some of the best residences of First Avenue West. Moreover, this method would involve considerable shunting across busy Tenth Street at the east end of the bridge. The switch would be located immediately to the south of Tenth Street, and each train passing between the two roads in either direction would have to cross Tenth Street twice.

With all these disadvantages, it is indeed unfortunate for Owen Sound that the second method is the only one that Mr. Tye can recommend from an economical point of view.

The only objection from an engineering standpoint that Mr. Tye takes to crossing the river at its mouth, is that for a considerable distance the interswitching trains must back up, and that this is objectionable in the winter. Exactly how insuperable this difficulty is, Mr. Tye does not say. He also refers to interference with navigation, but this could be obviated, at considerable expense, he intimates, by the construction of a bascule bridge instead of a swing bridge. "This route is economically justifiable as a whole," states Mr. Tye, but he estimates that the railways would lose about $1,500 a year as a result, at full switching charges. This crossing, however, has the decided advantage that it confines the railways entirely to the industrial districts, where they belong, keeping them out of the mercantile and residential sections.

Mr. Tye frankly makes it plain that he does not try to place any monetary value upon this advantage, which is a matter of civic convenience, esthetics and town planning. But the citizens of Owen Sound, expecting their city to grow and to become better able in the future to support, even at an annual loss, enterprises that are of benefit to the city as a whole, will no doubt take these items into serious consideration. Mr. Tye evidently expects them to do so, inasmuch as he carefully points out the very great disadvantages —from a community standpoint—of the plan that he recommends mainly for economical reasons.

Would it not be well for the officials of Owen Sound, before finally deciding this very vital question, to consult Thomas Adams, the town planning adviser to the Dominion government, or some other town-planning authority, regarding possible disastrous effects that any one of the various proposed plans might have upon the future growth, beauty, comfort, assessed valuation and general welfare of their city?

ENGINEERING INSTITUTE ELECTIONS

AT a meeting of the Engineering Institute of Canada held July 22nd in Montreal, the following elections and transfers were announced:—

Members.—H. W. Buck, Hewlett, N.Y.; A. R. Chambers, New Glasgow; G. P. Cole, Montreal; F. O. White, Temiskaming.

Associate Members.—J. R. Black, Sault Ste. Marie; J. L. Charles, Toronto; F. W. Clark, Niagara Falls; G. A. Colhoun, Hamilton; C. D. Dean, Toronto; L. L. Jacobs, Sault Ste. Marie; A. C. Loudon, Montreal; H. D. Maccaulay, St. John, N.B.; J. A. H. Marchand, Three Rivers; E. S. Martindale, Ottawa; H. R. McClymont, Toronto; C. R. McColl, Sandwich, Ont.; W. L. McFaul, Sault Ste. Marie; H. B. Pickings, Halifax; F. L. Richardson, St. John, N.B.; K. G. Ross, Sault Ste. Marie; H. N. Skolfield, New Glasgow; Francis Stidwill, Cornwall; C. W. Stokes, Montreal; G. M. Tripp, Victoria; W. D. Walcott, Toronto; C. S. Whitney, Niagara Falls; D. S. Wickwire, Halifax.

Juniors.—P. B. Buckley, Montreal; C. R. McCort, Montreal; R. C. Moore, Halifax; W. H. S. Richardson, Belleville; S. O. Roberts, Ottawa; B. N. Simpson, Toronto; G. O. Vogan, Toronto; C. O. Whitman, Sault Ste. Marie.

Transferred, Associate Members to Members.—A. E. Caddy, Campbellford, Ont.; J. A. DeCew, Mount Vernon, N.Y.; L. B. Elliot, Edmonton; B. M. Hill, Fredericton; S. B. Johnson, Ottawa; N. B. McLean, Ottawa; G. G. Murdoch, St. John, N.B.; A. V. Redmond, Winnipeg.

Transferred, Juniors to Associate Members.—L. C. Dupuis, Levis; J. A. Keefer, Victoria; A. M. Kirkpatrick, Ottawa; A. G. McLerie, Toronto; J. N. Stinson, Ottawa; L. W. Wynne-Roberts, Toronto.

Transferred, Students to Associate Members.—C. R. Avery, Toronto; J. H. A. E. Drolet, Quebec; J. E. Heroux, Quebec; R. P. Johnson, Niagara Falls; P. C. Kirkpatrick, Ottawa; C. C. Lindsay, Quebec; J. E. Ratz, Ottawa; W. E. Stephens, London; A. C. Wright, Ottawa.

Transferred, Students to Juniors.—R. D. Galbraith, Toronto; W. B. Redman, Toronto.

PERSONALS

JAMES, LOUDON & HERTZBERG, LTD., consulting engineers, Toronto, have been asked by the council of Chatham, Ont., to investigate the city's water supply and to report upon proposed improvements.

JOHN HEPINSTALL, of St. Thomas, Ont., who has been in Washington, D.C., engaged in special work for the U.S. Navy, is reported to have been appointed supervising engineer of design at the Charleston, W. Va., naval base.

D. A. R. MCCANNEL, who has been acting city engineer of Regina since April, 1917, can now drop the "acting" from his title, as the city council have appointed him as permanent head of the city's engineering staff, which he joined in 1911.

HON. FRANK CARVELL, who last week resigned as Minister of Public Works, has been appointed chairman of the Board of Railway Commissioners for Canada, succeeding SIR HENRY L. DRAYTON, who resigned to accept the post of Finance Minister in the Dominion cabinet.

WILLIAM SNAITH, office engineer for the Hydro-Electric Power Commission of Ontario on the construction of the Chippawa-Queenston power canal, has resigned to accept a position as principal assistant engineer on the staff of Frank Barber and R. O. Wynne-Roberts, consulting engineers, Toronto.

PROF. E. G. MATHESON, assistant engineer on the staff of the University of British Columbia, and acting head of the Department of Civil Engineering, has been appointed, under A. D. Swan, consulting engineer, to take charge of the surveys and borings in connection with the contemplated development of Vancouver Harbor.

CAPT. R. G. SNEATH, formerly a member of the Welland Canal engineering staff, has returned from overseas and has joined the radial railway department of the Hydro-Electric Power Commission of Ontario. Capt. Sneath graduated in civil and sanitary engineering at the University of Toronto in 1911 and 1912. He went overseas in the spring of 1916 with the 4th Division, and took part in a large number of important engagements.

LT.-COL. WILLIAM G. MACKENDRICK, president of the Warren Bituminous Paving Co. of Ontario, and formerly director of roads for the Fifth British Army, has been appointed an officer of the Legion of Honor by the French government. Col. MacKendrick rendered very valuable services while at the front, saving hundreds of thousands of dollars in road construction for the allied armies. For this work the British government conferred upon him the Distinguished Service Order and the Order of the British Empire.

R. R. SHAFTER, who is well known among Canadian engineers and contractors, has been appointed manager of the New York district office of the Traylor Engineering and Manufacturing Co., of Allentown, Pa. Mr. Shafter's territory will include New York State, New England and Eastern Canada. Before the war Mr. Shafter travelled throughout Eastern Canada as the Traylor Co.'s representative, but during the war he was general superintendent for the Traylor Shipbuilding Corporation, Philadelphia. Under Mr. Shafter's management, that corporation completed more 3,500-ton cargo carriers within two years than did any other shipyard on the Atlantic and Gulf coasts.

MAJOR A. J. MCPHERSON, formerly chairman of the Local Government Board of the Province of Saskatchewan and at one time deputy minister of public works of that province, has been appointed consulting engineer to the Saskatchewan Bureau of Public Health, succeeding the late T. Aird Murray. Major McPherson will also act as consulting engineer to the Local Government Board. He returned not long ago from France, where he served throughout the years 1917 and 1918 with the Canadian Engineers, at first as a field engineer on roads and defences, and later as second in command of the 11th Battalion. Major McPherson graduated in 1893 at the University of Toronto, Faculty of Applied Science and Engineering.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

P Peterson Construction Co., Ltd., 704 Birks Building, Vancouver. Contract price, $88,000. Work to be completed November 30th, 1919. A. E. Foreman, engineer.

Welland, Ont.—The Welland county council has awarded contracts for construction of roads as follows: Bethel Rd., division 16, 2.5 mls., to John Pirson, tender, $5,544 per ml.; Ridgeway, to E. B. Begy, concrete, length, 0.5 mls., tender, $19,500; Forks Rd., from Marshville to Port Colborne, 10 mls., water-bound macadam, to John Pirson, tender, $9,978.20 per ml. Rejected tenders, Ridgeway Rd., concrete construction, McCrae, Campaigne and Cook, $22,294; Gardner and Thomas, $24,135; Somerville and Dilworth, $22,220; tar-bound macadam surface, McRae, Campaigne and Cook, $11,072. Forks Rd., water-bound macadam, McRae, Campaigne and Cook, $12,672.45 per ml.; C. E. Kilmer, $19,370 per ml. Bituminous penetration paving on macadam road, McRae, Campaigne and Cook, no 3-year guarantee, $18.774 per ml.; with guarantee, $20,463.60 per ml.

Windsor, Ont.—The project of connecting the cities of Detroit and Windsor by means of a bridge, with 140 ft. clearance above the river, is being planned by Dr. J. A. L. Waddell, Kansas City and New York city.

Winnipeg, Man.—St. Andrew's municipality proposes to construct one hundred and forty miles of gravel roads to Winnipeg Beach. Estimated cost, $535,000.

Winnipeg, Man.—Tenders will be received until noon, August 9th, by the municipality of St. Francois Xavier for gravelling of 12 miles of Portage highway. E. Scott Shields, secretary-treasurer.

WATER, SEWAGE AND REFUSE

Burlington, Ont.—Contract has been awarded by the town council for construction of sewers on Caroline, Clarke North, Clark South, Green, St. Paul, Guelph, New, Hagar and Ontario Sts. to D. O. Johnson for $18,788.75. Rejected tender, Lorenzo and Liberio, $15,360.45. Deputy reeve, Wm. Bridgman.

Chatham, Ont.—The water board contemplate additions and improvements to the water supply. It is understood that the board is waiting for a report of the Hydro engineer before calling on a filtration expert. The present plant will

City Engineer Wanted

For the City of St. Thomas, Ont. Must be competent to take charge of all street improvements and other municipal engineering work, including that of the water works department. Applications to be addressed to the undersigned and to state age, experience and salary expected, and to enclose references.

E. A. HORTON, Mayor.

St. Thomas, Ont., August 6th, 1919. 319

TENDERS FOR BRIDGES

Sealed tenders, plainly marked as to contents, addressed to the undersigned, will be received up to 2 p.m. on Monday, August the 11th, 1919, for the construction of the following reinforced cement concrete culverts, bridges and abutments:—

(1) Located in the County of Dufferin—
- 1 culvert 4-foot span.
- 4 culverts 6-foot "
- 1 culvert 8-foot "
- 7 bridges 10-foot "
- 2 bridges 12-foot "
- 1 bridge 14-foot "
- 1 bridge 16-foot "
- 1 bridge 20-foot "
- 1 bridge 22-foot "
- 3 bridges 24-foot "

(2) Located in the Township of Albion—
- 1 pair of abutments for a 55-foot steel truss.
- 1 " " " " " 48-foot " "

(3) Located in the Township of Toronto Gore—
- 1 bridge 32-foot span.

(4) Located in the Township of Toronto—
- 1 bridge 12-foot span.

Plans and specifications may be seen and forms of tender and all information obtained at the office of the undersigned. The lowest or any tender not necessarily accepted.

WHEELOCK & CHRISTIE,
Civil Engineers,
Orangeville, Ont. 314

probably be remodelled, a new plant constructed and liquid chlorine used in the filtered water.

Galt, Ont.—Plans are being prepared for extension of water works system on certain streets. Town electrician Scott.

Moncton, N.B.—The city council has decided to extend the sewerage system on Cornell St., from Church to Henry St.

Oshawa, Ont.—The works committee has recommended that the contract be awarded for construction of sewer for the north part of the town to the McKnight Construction Co., Toronto. Contract price, $27,880. Other tender, Webster Construction Co., London, $33,661.40. These tenders did not include the 18 manholes and ladders, which will be provided by the town.

Regina, Sask.—The works department will commence construction of water works extensions about the end of the month. Work to be rushed to completion.

Sarnia, Ont.—Thos. Grace, who received the contract for installing a new intake pipe at the Point Edward water works, has commenced work. The derrick scow and dredge will arrive soon.

St. John, N.B.—The city council will extend the water and sewerage systems along Hawthorne Ave. Estimated cost, $14,000.

Wingham, Ont.—Contract has been awarded for construction of sewers and water mains to T. J. McLean ,and Co. Contract price, $4,500.

RAILWAYS

Arnprior, Ont.—The Galetta Power Co. will soon construct the new line from Galetta to Carp. Poles will be erected and the line completed at once. Mr. Locher, electrical engineer.

Calgary, Alta.—The commissioners of the city of Calgary contemplate extending the Bridgeland street car loop to serve a much larger area of that section. Superintendent McCauley.

Edmonton, Alta.—The Yukon Development league plans to connect Edmonton with Dawson by the extension of the E.D. and B.C. Ry. 1,200 miles through the Peace River country into the Liard district, along Finlayson River into the Yukon. Frank Lowe, president.

Fenelon Falls, Ont.—The local council will urge the Hydro-Electric Power Commission to extend the electric radial railway from Port Perry to Lindsay and thence northward through Victoria county.

Port Arthur, Ont.—The Canadian National Railways will construct an electric sub-station in connection with the new workhouse of the Port Arthur elevator.

Fort William, Ont.—The Canadian National Railways will widen the right-of-way between Empire Ave. and Frederica St., through West Fort William.

Galt, Ont.—At a meeting of civic and board of trade representatives from municipalities extending from Elmira to Hamilton, a resolution was passed requesting the Hydro-electric commission to proceed at once with reports on construction and operation of an electric railway to serve the district between Elmira, Galt, Hamilton and Guelph, also that the Hydro-electric commission be authorized by order in council to proceed at once with the construction of the Toronto to Hamilton electric railway. Another resolution set forth that sixty-two municipalities in Ontario had carried by-laws for the construction of Hydro-electric railways, and urged that the building of these railways be authorized by the provincial government by order in council. S. E. Charlton, Galt. D. Gross, mayor, Kitchener.

Halifax, N.S.—The city council will request the street railway to proceed with construction of a new line along Cogswell St. F. W. W. Doane, city engineer.

Halifax, N.S.—The Inverness Railway and Coal Co. will probably be purchased by the government and operated as part of the Canadian National Railways system.

Ottawa, Ont.—The city council has authorized the construction by the Ottawa Electric Railway Co. of a loop for the St. Patrick cars on Cobourg, Murray and Charlotte Sts.

Ottawa, Ont.—Tenders will be received until August 11th by the secretary, department of public works, Ontario, for electric wiring and fixtures required in connection with the alterations to the Normal and Model Schools, Ottawa. H. F. McNaughton, secretary.

Prince Albert, Sask.—The Canadian National Railways will start construction work immediately upon the new line from Prince Albert north to Paddock Wood. Andrew Knox, M.P., Prince Albert.

Sydney Mines, N.S.—A deputation from district No. 4 will request the Cape Breton Electric Co. to extend their lines a further 10 miles. Councillor McKeigan.

Toronto, Ont.—Commissioners Harris and Bradshaw are preparing a report on an expenditure of $5,000,000 for new civic street cars and extensions to the present civic system. T. L. Church, mayor.

Toronto, Ont.—It is expected that the new tracks on Pape Ave. will be laid very soon. The steel is in transit and is to be transferred to the Toronto Railway Co. upon arrival. R. C. Harris, commissioner of works, Toronto.

Windsor, Ont.—The city council has served notice of intention to purchase upon the officials of the Sandwich, Windsor and Amherstburg electric railway upon the expiration of its franchise in 1922. Mayor Winter, Windsor.

Woodstock, Ont.—Construction work on the Ingersoll-Woodstock section of the new provincial highway will not be commenced this year. It is stated that, owing to the Ingersoll-Thames Valley electric railway running directly along the route of the highway, some agreement will have to be made between the government and the railway.

FACTORIES AND LARGE BUILDINGS

Arnprior, Ont.—The Ottawa Valley Amusement Co. have awarded contract for construction of a new, modern theatre to be built on John St.

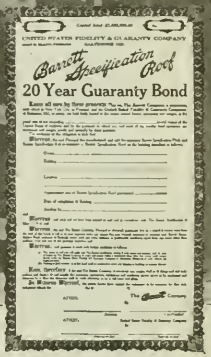
Guelph, Ont.—The Guelph housing commission has awarded contracts for construction of ten houses to the Ontario Co-operative Building Society, and also to Shepherd and Hicks.

Halifax, N.S.—Tenders will be received until noon, August 12th, by the department of public works for altera-

Barrett Specification Roofs

This roof carries the 20-year bond.

Barrett Specification 20-Year Roof on the Mercury Mills, Hamilton, Ont. Engineer and Architect—C. T. Main, Boston, Mass. Roofers—Dennis and Jocelyn, Hamilton, Ont.



UNITED STATES FIDELITY & GUARANTY COMPANY

Barrett Specification Roof

20 Year Guaranty Bond

This is the bond that guarantees your roof for 20 years.

Cover Your Investment with a 20-Year Guaranty Bond—

Every one knows that a structure of concrete and steel will endure for a generation and more.

But how about the roof that covers the structure?

Frequently that is not only an unknown quantity but a *liability* rather than an *asset*.

It is a short-sighted and costly policy to put a *poor* roof on a *good* building.

As one of the oldest and largest manufacturers of materials used in constructing roofs, we have done our part to make *all* roofs *good* roofs.

Years ago, for that reason, we induced the leading architects and engineers to unite in the adoption of The Barrett Specification as a satisfactory *standard specification*.

Now we go a step further by sending our Inspectors to check up on the construction, and if they find that The Barrett Specification has been properly complied with, we will, without charge, issue a 20-Year Guaranty Bond *exempting the owner from all further expense for repairs or up-keep on that roof for twenty years.*

This service may be had on all roofs of fifty squares or larger in all towns of 25,000 population or more and in smaller places *where our Inspection Service is available.*

Our guaranty is a real Surety Bond issued by one of the largest Surety Companies in the world. Our only requirements are that The Barrett Specification dated May 1, 1916, shall be strictly followed and that the roofing contractor shall be approved by us and his work subject to our inspection.

Thus, in spite of the fact that we do not build roofs ourselves, we are put in a position where we can guarantee the delivery of the long years of service which these roofs are capable of giving.

A copy of The Barrett 20-Year Specification, with roofing diagrams, sent free on request.

Fort William, Ont.—Engineers are preparing plans for the dredging of the Neebing River. F. H. Keefer.

Halifax, N.S.—Tenders will be received until noon, August 12th, by the department of public works, Ottawa, for construction of Orthopedic factory and for garage, both at Bellevue military hospital, Halifax. Plans, etc., at the office of chief architect, Ottawa; superintendent of military hospitals, Halifax, and overseer of Dominion buildings, central post-office, Montreal. R. C. Desrochers, secretary.

Kamloops, B.C.—Extensions to telephone and telegraph lines will be made in the following districts, 200 miles in the Kamloops and Okanagan districts, 22 miles from McKnight's to Adams Lake by Blucher Hall, 10 miles from Penantan Lake to Harper Ranch, Okanagan Falls to Meyers Flat, Slocan Junction to Slocan City, Windermere to Fairmont Springs. Estimated cost, $100,000. W. H. Stevens.

Kitchener, Ont.—The transportation committee of the board of trade will ask the board of works of the city council to co-operate in forming plans for a new subway under the railway tracks at King St. W. President Davidson.

Lorette, Man.—No tenders were received by the rural municipality of Lache, for grading and ditching north of sections 2 and 3-9-4 E., and on Dawson Rd., from lot 37 to 56. E. J. R. Arpin, secretary-treasurer.

North Lake, P.E.I.—Tenders will be received until noon, August 19th, by the department of public works, Ottawa, for construction of a boat harbor at North Lake. Plans, etc., at the offices of the district engineers at Charlottetown, P.E.I., Halifax, N.S., and at the post office, Elmira, P.E.I. R. C. Desrochers, secretary.

Port Stanley, Ont.—The department of public works contemplate dredging the harbor and constructing a new bridge at Port Stanley. District engineer Craig, Windsor, Ont.

Selkirk, Man.—Tenders will be received until noon, August 19th, by the department of public works, Ottawa, for construction of a crib wharf in front of the government fish hatchery, Dauphin River. Plans, etc., at the office of the district engineer, Winnipeg, Man., and post-office, Selkirk, Man. R. C. Desrochers, secretary.

Sherbrooke, Que.—Contract has been awarded to the Imperial Oil, Limited, by the city council for 180 tons of paving asphalt to be supplied in tank cars.

Simcoe, Ont.—Tenders will be received until 6 p.m., August 11th, by the town council for cast-iron pipe and sewer tile construction. G. R. Marston, town engineer; W. C. McCall, town clerk.

Stewart, B.C.—Tenders will be received until noon, August 20th, by the department of public works, Ottawa, for construction of a wharf. Plans, etc., at the office of district engineer, Prince Rupert, B.C., post offices at Vancouver and Stewart, B.C. R. C. Desrochers, secretary.

St. John, N.B.—Contract has been awarded to John Flood & Sons, for alterations and fittings in the new post office building.

St. John, N.B.—The city council has authorized construction of retaining walls along Hawthorne Ave. Estimated cost, $9,055.

Tisdale, Sask.—Tenders will be received until 4.30 o'clock, August 12th, by the department of public highways, Regina, for construction of two reinforced concrete abutments for bridge over Dog Hide Creek, at Tisdale, and for a bridge over Swan River north-east of Arran, both on the Can. Nat. Rys. H. S. Carpenter, deputy minister.

Toronto, Ont.—Tenders will be received by the board of control, Toronto, until noon, August 19th, for a revolving cantilever crane. T. L. Church, chairman.

Toronto, Ont.—Tenders will be received by the Canadian National Railways for 1,400,000 railway ties to be made and delivered between October 1st, 1919, and October 1st, 1920. 400,000 ties to be delivered on trans-continental, south of the St. Lawrence River, and 1,000,000 to be delivered on the Intercolonial, Halifax division. E. Langham, general purchasing agent, Toronto.

Toronto, Ont.—Tenders will be received until 4 p.m., August 11th, by the board of education, 155 College St., for moving a house in connection with Norway School, Kingston Rd., masonry work, Victoria school, smoke pipes, Kent school, midsummer repairs, including heating, ventilating, electric wiring, metal ceilings, cast iron grate bars, tile drains and electric motors in various schools. W. C. Wilkinson, secretary-treasurer.

Toronto, Ont.—Tenders will be received until noon, August 12th, by the board of control, city hall, for installation of sanitary conveniences in a number of dwelling houses. T. L. Church, chairman.

Toronto, Ont.—Tenders will be received until noon, August 19th, by the board of control, city of Toronto, for construction and delivery of 24-in. special castings. T. L. Church, chairman.

Toronto, Ont.—Tenders will be received until noon, August 25th, by the Canadian National Railways, Toronto, for 3,525,000 railway ties to be made and delivered between October 1st, 1919, and October 1st, 1920. Delivery to be made on the company lines as follows:—1,000,000 in British Columbia, 300,000 in Alberta, 1,500,000 between Winnipeg and O'Brien, 50,000 in Manitoba, 25,000 in Minnesota, 600,000 between Rainy River and Port Arthur, 50,000 on the Duluth, Winnipeg and Pacific lines in Minnesota. E. Langham, general purchasing agent, Canadian National Railways, Toronto.

Toronto, Ont.—The board of control has awarded contract for supply of 10 tank cars of asphalt for paving, to Imperial Oil, Ltd.

Wellesley Township, Ont.—The townships of Morning and Wellesley contemplate establishing a municipal telephone system serving both townships.

Winnipeg, Man.—Contract has been awarded by the Canadian National Railways, for grading and construction of culverts, mile 101.5 to mile 115.5, Thunderhill branch, to D. R. McDonald, Netherhill, Sask. H. A. Dixon, chief engineer.

Winnipeg, Man.—Tenders will be received until 3 p.m., August 11th, by the chairman, committee on Fire, Water, Light and Power, for repairing roof of six million gallon

reservoir at McPhillips St. Pumping Station. C. J. Brown, city clerk, Winnipeg.

Winnipeg, Man.—Tenders will be received until 12 o'clock noon, August 8th, by the Commissioners, Greater Winnipeg Water District, 501 Tribune building, Winnipeg, for the purchase of two 2-6-0 Mogul locomotives, f.o.b. Paddington Transfer. (Official advertisement in this issue). R. D. Waugh, chairman.

Winnipeg, Man.—Tenders will be received until noon, August 15th, by the department of public works, Manitoba, for construction of approximately forty-two miles of drainage ditches in drainage district No. 2. Total excavation, approximately 314,000 cu. yds. (Official advertisement in this issue). George A. Grierson, minister.

Tenders Called For

TENDERS WANTED

PROVINCE OF MANITOBA
DEPARTMENT OF PUBLIC WORKS

TENDERS FOR DRAINS
DRAINAGE DISTRICT No. 2

Sealed tenders, endorsed "Tenders for Drains, Drainage District No. 2," will be received at the office of the undersigned up to noon of Friday, August 15th, 1919 (at which time and place same will be opened in public), for the construction of approximately forty-two miles of Drainage Ditches in Drainage District No. 2, the work comprising approximately 314,000 cubic yards of excavation.

Full information, plans, profiles, specifications and forms of tender may be had on application at the Office of the Engineer, Mr. H. A. Bowman, Parliament Buildings, Winnipeg.

Bids will be considered for the whole or any portion of the work.

All tenders must be accompanied by an accepted cheque, payable to the Minister of Public Works, for an amount equal to Five per cent. (5%) of the amount of the tender.

The cheques of the successful tenderer or tenderers will be forfeit to the Government should the tenderer decline to execute a contract in accordance with his tender, or, having executed same, fails to carry out the provisions thereof.

The lowest or any tender not necessarily accepted.

GEO. A. GRIERSON,
Minister of Public Works.

Winnipeg, Manitoba,
August 1st, 1919. 318

GREATER WINNIPEG WATER DISTRICT

TENDERS FOR WATER LEVEL RECORDER

Sealed tenders will be received by the undersigned up to noon on Monday, 1st September, 1919, for an apparatus which will indicate at the head office of the District the water level in the District's surge tank in St. Boniface.

Information for Bidders may be seen at the Office of the Water District, 501 Tribune Building.

The lowest or any tender not necessarily accepted.

R. D. WAUGH,
Chairman of Commissioners,
Greater Winnipeg Water District,
306 501 Tribune Building, Winnipeg.

SALE OF UNUSED ARTICLES AT KINGSTON PENITENTIARY

Sealed tenders, addressed "Superintendent of Penitentiaries, Ottawa, and endorsed tenders for unused articles at Kingston Penitentiary," will be received until Saturday, August 30th, 1919, for the following:—

One Worthington type compound pump, Duplex, 12" x 19" by 10" x 10" stroke (repairs required).

Two Worthington boiler feed pumps, Duplex, 6" x 4" x 6" (require repairs).

One Smithvale boiler feed pump, 4½" x 3" x 4½" (in good condition).

One Worthington boiler feed pump, 6" x 4" x 6", Duplex (some parts missing).

One double acting Bilge pump, 3" x 6".

One galvanized iron 5" exhaust head.

One cast iron bath.

One 36" x 11" McGachin's blower with drive for Jones' underfeed stokers.

One Ideal centre crank engine 6" x 6" x 350 r.p.m. (in good condition).

One 6" x 9" vertical engine (requires repairs).

One 10" x 10" x 325 r.p.m. peerless self-oiling engine, direct connected to a 280 amp., 110 volt, D.C., united electric generator (in good order). Complete set of instruments (except volt meter, mounted on wooden template for generator).

One Daisy No. 7 high base, 1910 pattern, hot water furnace, no headers (good as new).

One Gurney-Oxford No. 8 low base hot water furnace, no headers (good as new).

Two Aetna hot water furnaces.

One old hot water furnace (scrap).

About 500 feet 4" cast iron piping with fittings.

Two 10-branch manifold headers for hot water furnace.

One tank 7' x 7' x 3' 6", ¼" plate, riveted and bolted.

One 42" x 11" x 36' (3" tubes), R.T. boiler, flush front (good for low pressure).

Eighteen feet of 2-ft. iron stack.

One piece boiler plate 6' x 6' x 11/16".

One R.T. boiler, 3' 6" x 10" x 38' (3" tubes) overhanging front (good condition and inspected).

One 30" x 6' x ⅜" plate, pressure tank (sound).

Sundry old radiators and steam traps.

Three 24" x 36" cast iron sinks.

Two marble mantel shelves, 5' x 1' x 1".

One marble mantel shelf 5' 6" x 1' x 1".

One marble mantel shelf 3' 6" x 1' 6" x 1".

Sundry pcs. white marble 1" thick.

One cast iron basin.

One punching press.

One fan.

One fence machine.

5½ pairs axle bearings.

14 axe boxes.

400 spiral wire pickets.

77 bushel baskets.

2 weaving looms.

94 pounds lea tow.

1,222 yards white warp.

1,926 enamel dishes (new).

Most of the above articles are in a fair state of repair and may be viewed at the Kingston Penitentiary, Kingston, Ont. Terms of sale cash. Articles purchased to be removed from the Kingston Penitentiary before September 30th, 1919. Check amounting to ten per cent. of tendered price must accompany all offers.

Papers inserting this notice without authority from the King's Printer will not be paid therefor.

(Signed) W. S. HUGHES, D.S.O.,
Superintendent of Penitentiaries.

The Canadian Engineer

A Weekly Paper for Civil Engineers and Contractors

Formulae for One-Story and Two-Story Bents

Elastic Deformation Method Used for Exact Determination of Stresses in Simple Types of Structures—Equations Derived Analytically to Save Time for Designing Engineers Engaged in Steel or Reinforced Concrete Construction

By E. MAERKER

Formerly Structural Engineer, Toronto Power Co.

WHEN designing one-story and two-story bents, without diagonals, subject to horizontal forces, engineers usually base their design upon some assumption as to the location of the points of contraflexure of the columns.

Following such assumption, the bending moments produced in the columns by the horizontal forces are easily calculated. It is evident, however, that the location of the points of contraflexure is dependent upon the relative moments of inertia of the columns and struts, since the stiffness of the struts as compared to the columns determines the amount of deflection at the joints. The results obtained by this method of calculation are, of course, only approximate.

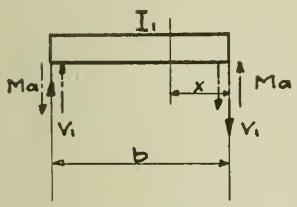

FIG. 1

In this article, an analysis, based upon the elastic theory of structures, is made in order to determine the bending moments and the location of the points of contraflexure in the columns of a two-story bent. From the formulæ thus derived, the ten different cases illustrated by Figs. 6 to 15 are deduced.

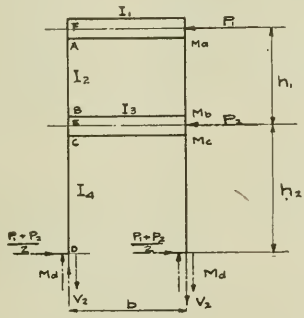

FIG. 2

If the structure be subject to vertical forces as well as horizontal, it is but necessary to make an algebraical addition of the stresses produced by the different forces.

In this article the following assumptions are made:—

(1)—That each column takes one-half the load.

(2)—That the connection of the column to the strut is rigid.

(3)—That the foundations are non-yielding.

All dimensions are expressed in the same units, and the following nomenclature is used:—

P_1 and P_2 Horizontal forces.

h_1 and h_2 and b Distances as shown in figures.

I_1 and I_3 Moment of inertia of upper and lower girder, respectively.

I_2 and I_4 Moment of inertia of upper and lower column, respectively.

M_a Moment at junction of upper column and upper girder.

M_b Moment at junction of upper column and lower girder.

M_c Moment at junction of lower column and lower girder.

M_d Moment at base of column.

x_1 and x_2 Distances to points of contraflexure.

Referring to Fig. 2, the moments about E may be expressed as follows:—

$$P_1h_1 = 2M_b+V_1b.$$

Solving for V_1,

$$V_1 = (P_1h_1-2M_b)/b \quad \ldots\ldots(1)$$

Again referring to Fig. 2, the moments about D may be expressed as follows:—

$$P_1(h_1+h_2)+P_2h_2 = 2M_d+V_2b.$$

Solving for V_2,

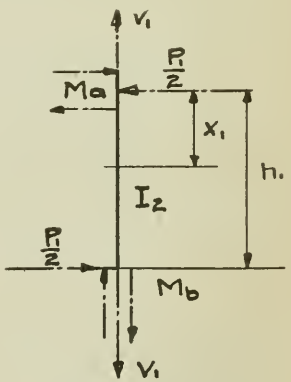

FIG. 3

$$V_2 = [P_1(h_1+h_2)+P_2h_2-2M_d]/b \quad \ldots\ldots(2)$$

Then,

$$V_2-V_1 = [(P_1+P_2)h_2-2M_d+2M_b]/b \quad \ldots\ldots(3)$$

Referring to Fig. 1, the moments about F are

$$V_1b = 2M_a.$$

Solving for M_a and substituting the value for V_1 from Equ. 1,

$$M_a = (P_1h_1/2)-M_b \quad \ldots\ldots(4)$$

Referring again to the moments about E (see Fig. 2),

$$(P_1+P_2)h_2-2M_d = 2M_c.$$

From this,

$$M_c = \tfrac{1}{2}(P_1+P_2)h_2-M_d \quad \ldots\ldots(5)$$

The equation of the elastic curve (see Fig. 1) is

$$EI_1(d^2y/dx^2) = V_1x-M_a.$$

By integrating,

$$EI_1(dy/dx) = \tfrac{1}{2}V_1x^2-M_ax+C_1.$$

When $dy/dx = (dy/dx)_A$, and $x = 0$,

$$C_1 = EI_1(dy/dx)_A.$$

By substituting in above,

$$EI_1(dy/dx) = \tfrac{1}{2}V_1x^2-M_ax+EI_1(dy/dx)_A.$$

Integrating again,

$$EI_1y = \tfrac{1}{6}V_1x^3-\tfrac{1}{2}M_ax^2+EI_1(dy/dx)_Ax+C_2.$$

$C_3 = 0$. When $y = 0$ and $x = b$, substituting for V_1 from Equ. 1, and for M_b from Equ. 4,

$$(dy/dx)_A = M_a b/6EI_1 \quad \ldots\ldots\ldots\ldots\ldots\ldots (6)$$

For convenience, x and y axis will be turned through 90 degs. when considering vertical posts.

Referring to Fig. 3,

$$EI_2(d^2y/dx^2) = M_a - \tfrac{1}{2}P_1x.$$

By integrating,

$$EI_2(dy/dx) = M_a x - \tfrac{1}{4}P_1x^2 + C_1.$$

When $dy/dx = (dy/dx)_A = M_a b/6EI_1$, and $x = 0$,

$$C_1 = M_a bI_2/6I_1.$$

Substituting this value for C_1 in the above equation,

$$EI_2(dy/dx) = M_a x - \tfrac{1}{4}P_1x^2 + (M_a bI_2/6I_1).$$

When $dy/dx = (dy/dx)_B$, and $x = h_2$,

$$(dy/dx)_B = (dy/dx)_C = (M_a h_1/EI_2) + (M_a b/6EI_1) - (P_1h_2^2/4EI_2) \quad \ldots\ldots\ldots (7)$$

Referring to Fig. 4,

$$EI_2(d^2y/dx^2) = (V_2 - V_1)x - M_b - M_c.$$

Integrating,

$$EI_2(dy/dx) = (V_2 - V_1)\tfrac{1}{2}x^2 - (M_b + M_c)x + C_1$$

When $dy/dx = (dy/dx)_B$, and $x = 0$,

$$C_1 = EI_2(dy/dx)_B.$$

Substituting these values in the above equation,

$$EI_2(dy/dx) = (V_2 - V_1)\tfrac{1}{2}x^2 - (M_b + M_c)x + (M_a h_1 I_2/I_1) + (M_a bI_2/6I_1) - (P_2h_1^2I_2/4I_1).$$

Integrating again,

$$EI_2y = (V_2 - V_1)\tfrac{1}{6}x^3 - (M_b + M_c)\tfrac{1}{2}x^2 + [(M_a h_1 I_2/I_1) + (M_a bI_2/6I_1) - (P_2h_1^2I_2/4I_1)]x + C_2.$$

$C_2 = 0$. When $y = 0$ and $x = b$,

$$(M_b + M_c)\tfrac{1}{2}b - M_a[(h_1I_2/I_1) + (bI_2/6I_1)] = (V_2 - V_1)\tfrac{1}{6}b^2 - (P_2h_1^2I_2/4I_1).$$

Substituting for $(V_2 - V_1)$ from Equ. 3, and for M_b and M_c from Equ. 4 and Equ. 5, respectively, and solving for M_d,

$$M_d = \tfrac{1}{2}(P_2h_1 + P_2h_2 + P_2h_2) - M_a\{1 + (6I_2/b)[(h_1/I_1) + (b\ 6I_1)]\} + 3P_2h_1^2I_2/2bI_2 \quad \ldots\ldots\ldots\ldots (8)$$

Referring to Fig. 5, $EI_4(d^2y/dx^2) = M_d - \tfrac{1}{2}(P_1 + P_2)x$. Integrating,

$$EI_4(dy/dx) = M_d x - \tfrac{1}{4}(P_1 + P_2)x^2 + C_1.$$

$C_1 = 0$. When $dy/dx = (dy/dx)_C$ and $x = h_2$,

$$(M_a h_1 I_4/I_2) + (M_a bI_4/6I_1) - (P_2h_1^2I_4/4I_2) = M_d h_2 - \tfrac{1}{4}(P_1 + P_2)h_2^2.$$

Solving for M_d,

$$M_d = (M_a I_4/h_2)[(h_1/I_2) + b/6I_1)] + \tfrac{1}{4}(P_1 + P_2)h_2 - (P_2h_1^2I_4/4I_2h_2) \quad \ldots\ldots\ldots\ldots (9)$$

Solving for M_a from Equ. 8 and Equ. 9,

$$M_a = \{\tfrac{1}{4}(2P_2h_1 + P_2h_2 + P_2h_2) + (3P_2h_1^2/2I_2)[(I_4\ 6h_2) + (I_2/b)]\} \div \{1 + [(h_1/I_2) + (b/6I_1)][(I_4/h_2) + (6I_2/b)]\} \quad \ldots\ldots (10)$$

From Equ. 5 and Equ. 9,

$$M_c = \tfrac{1}{4}(P_1 + P_2)h_2 + (P_2h_1^2I_4/4I_2h_2) - (M_a I_4/h_2)[(h_1/I_2) + (b/6I_1)] \quad \ldots\ldots\ldots\ldots (11)$$

Case 1 (Fig. 6)

Fig. 6 corresponds to Fig. 1, and the four equations for the moments M_a, M_b, M_c and M_d are, respectively, equations 10, 4, 11 and 5 given above.

Figs. 7 to 15, both inclusive, are special cases, and the values for their moments were obtained by substituting the proper values in the above equations, as shown. Values for points of contraflexure were derived by equating the second derivative of the equation for the elastic curve equal to zero. For Case 1 (Fig. 6),

$$x_1 = 2M_a/P_1 \quad \ldots\ldots\ldots\ldots\ldots\ldots (12)$$

$$x_2 = 2M_d/(P_1 + P_2) \quad \ldots\ldots\ldots\ldots\ldots\ldots (13)$$

Case 2 (Fig. 7)

Fig. 7 represents Case 2,

$M_d = 0$. Substitute for M_d in Equ. 8.

$$M_a = [\tfrac{1}{2}(P_2h_1 + P_2h_2 + P_2h_2) + (3P_2h_1^2I_2/2bI_2)] \div \{1 + (6I_2/b)[(h_1/I_2) + (b/6I_1)]\} \quad \ldots\ldots\ldots (14)$$

For M_b, see Equ. 4.

Substituting $M_d = 0$ in Equ. 5.

$$M_c = \tfrac{1}{2}(P_1 + P_2)h_2 \quad \ldots\ldots\ldots\ldots\ldots\ldots (15)$$

For x_1, see Equ. 12.

Case 3 (Fig. 8)

Fig. 8 represents Case 3.

$P_2 = 0$, $I_2 = 0$, $I_4 = I_2$, and $h_1 + h_2 = h$. Substituting in Equ. 10,

$$M_a = (3P_2h^2I_1)/2(bI_2 + 6hI_1) \quad \ldots\ldots\ldots\ldots\ldots\ldots (16)$$

For M_b, see Equ. 4.

$$x_2 = 2M_b/P_1 \quad \ldots\ldots\ldots\ldots\ldots\ldots (17)$$

Case 4 (Fig. 9)

Fig. 9 represents Case 4.

$M_b = 0$. Substituting in Equ. 4,

$$M_a = P_2h/2 \quad \ldots\ldots\ldots\ldots\ldots\ldots (18)$$

Case 5 (Fig. 10)

Fig. 10 represents Case 5.

$P_2 = 0$. Substituting in Equ. 10,

$$M_a = \{\tfrac{1}{4}P_1(2h_1 + h_2) + (3P_2h_1^2/2I_2)[(I_4/6h_2) + (I_2/b)]\} \div \{1 + [(h_1/I_2) + (b/6I_2)][(I_4/h_2) + (6I_2/b)]\} \quad \ldots\ldots\ldots (19)$$

Substituting $P_2 = 0$ in Equ. 4,

$$M_b = (P_1h_2/2) - M_a \quad \ldots\ldots\ldots\ldots\ldots\ldots (20)$$

Substituting $P_2 = 0$ in Equ. 11,

$$M_c = \tfrac{1}{4}P_1h_2 + (P_1h_2^2I_4/4I_2h_2) - (M_a I_4/h_2) \times [(h_1/I_2) + (b/6I_1)] \quad \ldots\ldots\ldots\ldots\ldots (21)$$

Substituting $P_2 = 0$ in Equ. 5,

$$M_d = (P_1h_2/2) - M_c \quad \ldots\ldots\ldots\ldots\ldots\ldots (22)$$

For x_2, see Equ. 12.

$$x_2 = 2M_d/P_1 \quad \ldots\ldots\ldots\ldots\ldots\ldots (23)$$

Case 6 (Fig. 11)

Fig. 11 represents Case 6.

$P_2 = 0$ and $M_d = 0$. Substituting in Equ. 14,

$$M_a = [\tfrac{1}{2}P_1(h_1 + h_2) + (3P_1h_1^2I_2/2bI_2)] \div \{1 + (6I_2/b)[(h_1/I_2) + (b/6I_1)]\} \quad \ldots\ldots\ldots (24)$$

For M_b, see Equ. 20.

Substituting $P_2 = 0$ in Equ. 15,

$$M_c = P_1h_2/2 \quad \ldots\ldots\ldots\ldots\ldots\ldots (25)$$

For x_1, see Equ. 12.

Case 7 (Fig. 12)

Fig. 12 represents Case 7.

$P_1 = 0$. Substituting in Equ. 10,

$$M_a = (\tfrac{1}{4}P_2h_2) \div \{1 + [(h_1/I_2) + (b/6I_1)][(I_4/h_2) + (6I_2/b)]\} \quad \ldots\ldots (26)$$

Substituting $P_1 = 0$ in Equ. 4,

$$M_b = -M_a \quad \ldots\ldots\ldots\ldots\ldots\ldots (27)$$

Substituting $P_1 = 0$ in Equ. 11,

$$M_c = \tfrac{1}{4}P_2h_2 - (M_a I_4/h_2)[(h_1/I_2) + (b/6I_1)] \quad \ldots\ldots\ldots (28)$$

Substituting $P_1 = 0$ in Equ. 5,

$$M_d = \tfrac{1}{2}P_2h_2 - M_c \quad \ldots\ldots\ldots\ldots\ldots\ldots (29)$$

$$x_2 = 2M_d/P_2 \quad \ldots\ldots\ldots\ldots\ldots\ldots (30)$$

Case 8 (Fig. 13)

Fig. 13 represents Case 8.

$P_2 = 0$ and $M_d = 0$. Substituting in Equ. 14,

$$M_a = (\tfrac{1}{2}P_2h_2) \div \{1 + (6I_2/b)[(h_1/I_2) + (b/6I_1)]\} \quad \ldots\ldots (31)$$

For M_b, see Equ. 27.

From Equ. 15,

$$M_c = P_2h_2/2 \quad \ldots\ldots\ldots\ldots\ldots\ldots (32)$$

Case 9 (Fig. 14)

Fig 14 represents Case 9.

P_2 acts in opposite direction to P_1. Substituting $-P_2$ for $+P_2$ in Equ. 10,

$$M_a = \{\tfrac{1}{4}(2P_1h_1 + P_1h_2 - P_2h_2) + (3P_1h_1^2/2I_2)[(I_4/6h_2) + (I_2/b)]\} \div \{1 + [(h_1/I_2) + (b/6I_1)][(I_4/h_2) + (6I_2/b)]\} \quad \ldots\ldots\ldots (33)$$

For M_b, see Equ. 4.

From Equ. 11,

$$M_c = \tfrac{1}{4}(P_1 - P_2)h_2 + (P_1h_1^2I_4/4I_2h_2) - (M_a I_4/h_2)[(h_1/I_2) + (b/6I_1)] \quad \ldots\ldots\ldots (34)$$

From Equ. 5,

$$M_d = \tfrac{1}{2}(P_1 - P_2)h_2 - M_c \quad \ldots\ldots\ldots\ldots\ldots\ldots (35)$$

For x_1, see Equ. 12.

$$x_2 = 2M_d/(P_1 - P_2) \quad \ldots\ldots\ldots\ldots\ldots\ldots (36)$$

Case 10 (Fig. 15)

Fig. 15 represents Case 10.

P_2 acts in opposite direction to P_1, and $M_d = 0$. Substituting $-P_2$ for $+P_2$ in Equ. 14,

$$M_a = [\tfrac{1}{2}(P_1h_1 + P_1h_2 - P_2h_2) + (3P_1h_1^2I_2/2bI_2)] \div \{1 + (6I_2/b)[(h_1/I_2) + (b/6I_1)]\} \quad \ldots\ldots\ldots (37)$$

For M_b, see Equ. 4.

From Equ. 15,

$$M_c = \tfrac{1}{2}(P_1 - P_2)h_2 \quad \ldots\ldots\ldots\ldots\ldots\ldots (38)$$

And, as previously, $x_1 = 2M_a/P_1$.

LIGNITE BOARD ENCOUNTERED DIFFICULTIES

Published Information Led the Board to Believe that the Carbonization of Lignites Had Advanced Further Than Investigation Proved to be the Case

THAT the Lignite Utilization Board of Canada met difficulties in designing a plant for the economical carbonization of Saskatchewan's lignite in commercial quantities, is shown by the following statement recently issued by the Board:—

At the commencement of the Board's activities on October 1st, 1918, it was decided that every briquetting and coal treating plant in the United States and Canada, where information pertinent to lignite carbonization might be available, ought to be visited by the board's engineers, in order that the last word on carbonizing and briquetting might be obtained. At that time it was hoped that, as a result of this investigation, the board's engineers would be able, on their return, to recommend that such-and-such carbonizers be adopted, such-and-such mixers, and such-and-such briquetting presses. It would then have been possible to proceed immediately with the erection of the plant and purchase of machinery. It should be noted that a great deal of published information had led the board to believe that the carbonization of lignite had advanced further than actual personal investigation proved to be the case. Their expectations, therefore, in regard to carbonizing of lignite were not realized, and it became necessary for the board to develop a special type of carbonizer that might be suitable for the low-grade Saskatchewan deposits.

The results of the investigation of crushers, dryers, mixers and presses were, however, much more encouraging. It became evident that various commercial machines could be obtained in the open market that would be suitable for the board's needs with but slight alterations.

Present Program

The present program may be briefly summed up as follows: The board is developing a special type of carbonizer, and within a couple of weeks the preliminary trials of this apparatus will be made. In the event of success, the board's plans will permit it to start the erection of a plant during this coming autumn. In the event of this carbonizer not being successful, further designs will be made, but the board is determined that not one dollar will be spent on large retort equipment until it is absolutely certain of the ground now being explored.

In addition to its own researches, the board has arranged with a number of investigators in Canada, the United States and Great Britain, to undertake certain experimental programs. In this way, the board is sure of having at its command the best scientific information along these lines that can possibly be secured.

Site of Proposed Plant

The board has collected as much data as possible on the physical characteristic of the whole Souris field. This data includes information on depth, width, quality and ash content of the seams in each mine, the stratification of the whole area, water supply, topographical characteristics, approximate values of land, quantity of slack available in mines, population of the various towns, and railway facilities. In addition, the board has come to an arrangement with the Department of the Interior whereby no new mining lease within a radius of 20 miles of Estevan will be granted without the board's certificate that such lease will not conflict with the future operations of the board. In this way the interests of the public are safeguarded. No immediate decision, however, will be announced as to the exact location of the proposed plant.

Difficulties of Board's Program

The main divisions of the process of producing a carbonized and briquetted domestic fuel from raw lignite are as follows: (a) Crushing, (b) drying, (c) pulverizing, (d) carbonizing, (e) mixing, (f) briquetting, (g) water-proofing, and (h) cooling. These steps will be discussed briefly, in order that it may be clearly seen what the board is attempting to do. It must be noted that the following remarks are applicable specifically to the Saskatchewan lignites.

(a) and (c). Enough information regarding crushing and pulverizing is at hand to know that these processes can probably be carried out by means of some type of standard apparatus at present on the market. In any event only slight changes will be necessary in order to make existing machinery practicable.

(b). Certain technical difficulties exist with the drying. Standard machinery that can be purchased in the open market, however, will probably be suitable.

(d). As mentioned above, the question of the commercial carbonization of lignite is one that presents, at the moment, the most difficulty to the board. It is also at this point that the board's objectives differ most widely from those of so many firms in the United States that are retorting coal on a large scale. The latter have in mind the production of the maximum quantity of by-products, while the defined objective of the Lignite Board is the production of the maximum number of heat units in the residue, in order that it may be available as a domestic fuel. These differences are the more marked when it is remembered that the successful coal-treating firms of the United States are dealing with a much higher grade of fuel than the Lignite Utilization Board. There is no question that the carbonization of the lignite *can* be accomplished. The only point is, how cheaply can it be done on a commercial scale with commercial apparatus and with commercial quantities. In order to solve this specific problem, the board, through the courtesy of the Department of Mines, Mines Branch, has been erecting a small experimental plant at Ottawa, which is, however, to be suplied with units that, though small, may still be regarded as commercial. In this plant the new carbonizer is one toward which the board is looking with great hopes.

Mention has already been made of the fact that the board has not only its own investigations under way, but has arranged with a number of well-known scientists to undertake special research work on carbonization.

(f). The question of briquetting is one that is practically solved, and the board's present objective is to discover the minimum quantities of those binders which are available in commercial quantities in the west. It is interesting to note that the amount of binder necessary for carbonizing lignite is very much in excess of the quantity of the same binder necessary for briquetting anthracite. Enough information with regard to briquetting and binding, however, is now in the board's possession to enable it to state that, for briquetting presses, it will probably be able to utilize existing commercial machinery with but slight alterations.

(g). In order that the briquettes may be smokeless, it will be necessary to subject them to a heat treatment, and it only remains to determine whether this heat treatment can be made sufficiently cheap to warrant its adoption.

(h). Cooling. This is purely a commercial detail.

Probable Future Construction

At present the board wishes to guard against any absolute promises, because future construction is entirely dependent upon the results of the experimental investigations now going on at Ottawa and elsewhere. The board has plans and layouts sufficiently advanced to proceed at the earliest moment with the letting of contracts, purchase of land, machinery, etc., provided the experiments are successful. The board hopes that erection of the plant itself may be started by October or November, 1919. If the experiments are not successful, the whole matter must wait until success is achieved, because the board will not under any circumstances spend public funds for one dollar's worth of capital equipment that might afterwards prove unsuitable.

Jones & Attwood, Ltd., of Stourbridge, Eng., who are the owners of the patents on the activated sludge method of sewage disposal, and who have been the pioneers in its development in England, are transferring the activated sludge department of their business to a newly-formed firm, Activated Sludge, Limited, of Stourbridge.

EFFECT OF RODDING CONCRETE

By F. E. Giesecke
Professor of Architectural Engineering, University of Texas, Austin, Tex.

In a series of tests made at the University of Texas to determine the physical properties of dense concrete as determined by the relative quantity of cement, described in Bulletin No. 1815, published March 10th, 1918, only sufficient mixing water was used to secure a concrete of workable consistency. For comparison, however, a few specimens were prepared with an excess of water, which produced a very considerable reduction in strength, as was shown in Fig. 8 of the above-mentioned bulletin.

In practical operation it is almost absolutely necessary to use enough excess water to make the concrete sufficiently fluid to be handled in wheel-barrows, carriages or tubes, and so that it will flow readily into the forms and between and around the reinforcing steel.

With these facts before us—that an excess of water must be used to place the concrete correctly and economically, and that this excess water materially reduces the strength of the concrete—the question naturally arises, what, if anything, can be done to repair the injury that is done by the excess water?

To answer this question, G. A. Parkinson, assistant testing engineer, University of Texas, made a number of

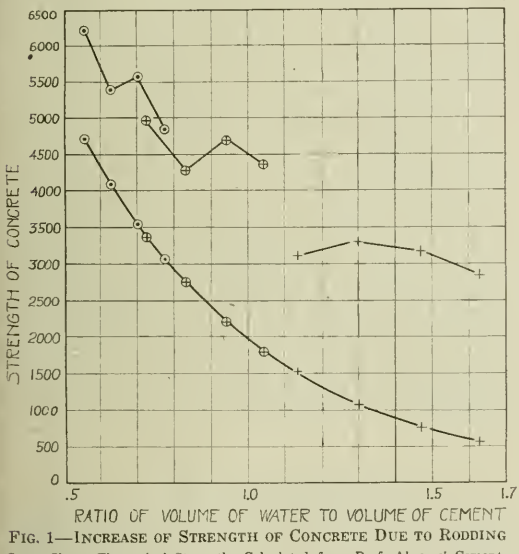

Fig. 1—Increase of Strength of Concrete Due to Rodding

Curve Shows Theoretical Strengths Calculated from Prof. Abrams' Cement-Water Formula (Assuming the Constants as 7 and 14,000), While Broken Lines Show Tested Strengths of Same Concrete after Roddings.

experiments in the fall and winter of 1917, to determine the effect of removing the excess water from the concrete after the latter had been deposited in the forms.

In these experiments the excess water was removed by forcing a pointed iron rod into the concrete while the latter was still soft; the effect of running such a rod into the concrete is to permit the excess water and entrapped air to escape upward, and to compact the aggregate; as a result the density of the concrete is increased about 4%.

This method of treating concrete has been named "rodding"; it is quite similar to "spading," but differs materially from "tamping." The results of Mr. Parkinson's early work were so very satisfactory that an extended series of tests was begun in June, 1918, and this was followed by other series of tests as new phases of this method of treating concrete developed. Some of these tests are still incomplete; but considerable important data have been secured and the following will be of interest.

Fig. 2 shows graphically the ultimate unit compressive strengths of fifty-four 6 by 12-in. cylinders. The concrete had the following composition:—

Material.	Percentage.
Cement	14.40
Passing 35-mesh sieve	4.35
Passing 12-mesh sieve and retained on 35-mesh sieve	9.00
Passing ¼-in. sieve and retained on 12-mesh sieve	13.00
Passing ¾-in. sieve and retained on ¼-in. sieve	29.50
Passing 1¼-in. sieve and retained on ¾-in. sieve	29.75
	100.00
Water	10.00

The 54 cylinders were divided into three groups of 18 cylinders each. In each group one cylinder was not rodded; the remaining 17 were rodded from one to seventeen times. In one group a 10-min. interval was allowed between roddings; in another a 20-min. interval; and in the third group, a 30-min. interval. The first rodding was applied soon after the moulds were filled; i.e., without waiting for the full interval of time assigned the particular series to pass. By one rodding is to be understood the pushing of a pointed

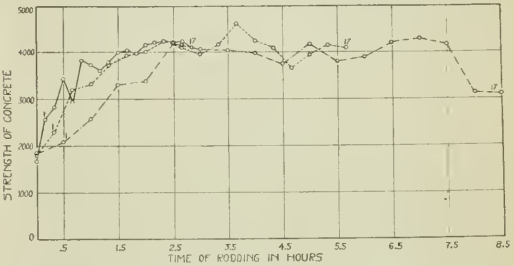

Fig. 2—Variation in the Increase of Strength of Concrete, Due to Rodding, with the Number of Roddings

iron rod into the concrete to the full depth of the concrete once for every surface area of about 3 sq. ins.; i.e., about ten times for a 6-in. cylinder.

It is interesting to note:—

(a)—That the maximum strength is about 130% more than that of the unrodded specimens.

(b)—That all three series acquired their maximum strength in about 2 or 2½ hrs.

(c)—That for the 30-min. interval it required 5 roddings; for the 20-min. interval, 7 roddings; and for the 10-min. interval, 14 roddings, to secure the maximum strength.

It is probable that the length of time and the number of roddings necessary to secure the maximum strength vary with the temperature and with the percentages of cement and water.

Fig. 1 shows graphically by the broken lines the average ultimate unit compressive strengths of thirty-six 6 by 12-in. cylinders arranged in twelve groups of three cylinders each.

The intermediate group, represented by crosses within circles, was made of concrete having the same composition as that represented in Fig. 2; but the mixing water was 7% for three cylinders, 8% for three, 9% for three, and 10% for three. This concrete contains cement at the rate of about six sacks of cement per cubic yard of concrete.

The two other groups are of similar composition, but the cement content changed to about four and eight sacks respectively per cubic yard. The percentages of water for the lean mixes were the same as for the intermediate, but for the rich mixes they were increased, respectively, to 7½, 8½, 9½ and 10½%.

To compare these results with the strength of plain concrete, the work of the Lewis Institute, of Chicago, as reported by Prof. Abrams, was selected as being probably the latest and most reliable, and probably also the most appropriate, since it gave special attention to the effect of excess water on the strength of the resulting concrete.

According to the Lewis Institute tests the strength of concrete is a function of the ratio of the volumes of water to that of the cement used in the production of the concrete, and is 14,000 ÷ 7^R lbs. per sq. in. for cement 28 days old, R being the ratio referred to, and the weight of one cubic foot of cement being assumed as 94 lbs. The curved line shows the strength of the twelve groups of specimens as calculated by this formula.

An inspection of Fig. 1 shows:—

(1)—That the effect of rodding concrete is more beneficial with lean than with rich mixes, and that it is more beneficial with wet than with dry mixes.

(2)—That the average strength of 8-sack concrete can be increased about 45% by rodding; that of 6-sack, about 60%; and that of 4-sack, about 220%.

To appreciate how well the values shown in Fig. 2 (determined by test July 11th, 1919) check with those shown by the broken line in Fig. 1 (determined by test March 19th, 1919) and with those shown by the curved line in Fig. 1 (calculated from the Lewis Institute formula), notice that the average strength of the unrodded specimens shown in Fig. 2 is about 1,800 lbs., and that this is almost exactly the same as that shown by the curved line in Fig. 1 for the 6-sack concrete with 10% of water; also that the strength shown by Fig. 2 increases gradually with the roddings to about 4,250 lbs., which is a trifle less than that shown by the broken line in Fig. 1 for the 6-sack concrete with 10% of water.

WORLD IS ON HIGHER PRICE LEVEL*

By T. S. Holden

Investigator Economics Section, Division of Public Works and Constructive Developments, U.S. Department of Labor

IN our capacity as buyers of commodities we have proceeded on the assumption that it was desirable for prices to fall. Falling prices rarely stimulate business. They usually stimulate waiting for further declines. A period of falling prices is usually a period of business depression. The past six months has been remarkable for the small number of business failures. It is entirely possible that a sharp decline in prices might have been accompanied by a greater number of business failures than there has been, attended with a much greater menace of unemployment. A financial panic might have been within the bounds of possibility.

Many of those who have been deferring building projects and the resumption of production of commodities have stated that they were waiting until prices and wages should have returned to "normal." The word "normal" has been used extensively in this connection and most of those who have used it have not appreciated the true meaning of the word. Not only in connection with prices and wages has this term been used incorrectly, but courts and public utility commissions have used the term loosely when speaking of valuations of properties. It is worth while to determine just what this word means in connection with prices, wages and property values, not in the interest of academic precision but simply to aid clear thinking on this subject.

A paper entitled "Appraisals and Rate Making" was read March 20th at the annual meeting of the Illinois Gas Association by Cecil F. Elmes, an eminent engineer. In this paper Mr. Elmes presented with the utmost clarity and force, certain aspects of the price situation as affecting valuations of public utility properties and the principles of rate making. In the course of his discussion Mr. Elmes dwelt at some length on the misconception of the term "normal." He presented curves showing the fluctuations of prices in England on five basic articles, wheat, iron, lead, cattle and sheep, covering a period of six centuries. He also presented curves showing fluctuations of artisans' wages, both in terms of money and in terms of the quantity of wheat the wages would buy, covering the same extended period. He pointed out that in the case of each one of these curves the fluctuations are so erratic that it is impossible to draw a horizontal straight line, an oblique straight line, or a mathematical curve which could in any sense serve as a median about which the prices or wages fluctuate. Consequently, it is not possible to define mathematically in terms of past experience the "normal" price of a given commodity, or "normal" wages. Neither is it possible to thus define a "normal" rate of increase in prices or wages.

Not everyone has the opportunity to consult the records of the British museum, as Mr. Elmes has had, for the purpose of studying this subject. There is, however, another authority which is readily accessible to all, Webster's Dictionary. Webster defines the term in connection with economics as follows:—

"Pertaining or conforming to a more or less permanent standard, from which, if the individual phenomena deviate on either side, such deviations are to be regarded as self-corrective. Thus, in economics, the normal price is a price which corresponds to the cost of production."

Relation of Price and Cost

The standard to which a price must conform is, therefore, not necessarily a price that we are accustomed to, or that we were accustomed to five years ago. Mr. Elmes has shown that past experience has established no mathematical standard to which a price may be expected to conform. Webster says that the standard is the cost of production. In 1919 the standard is the cost of production in 1919, and not the 1914 cost of production. There is no justification for assuming that $12 is an unfair price for a pair of shoes to-day, simply because the same pair of shoes might have been bought in 1914 for $6. The only criterion for the present price of shoes is the present cost of production of the shoes plus a reasonable margin of profit to those concerned in the making and the selling of the shoes.

Similarly "normal" wages in 1919 must not necessarily conform to the wage scale of 1914. "Normal" wages in 1919 must cover the cost of living in 1919 with a reasonable margin.

Similarly, the fact that the customary street car fare in the past has been 5 cents is not necessarily an indication that a 5-cent fare is the "normal" fare in 1919. As in the case of prices and wages, the standard of the rate to be paid for the services rendered by any public utility corporation is not fundamentally the rate the public has been accustomed to pay, but the cost of production of the commodity that is being sold, whether it be gas, electric power or transportation.

It is also true that the normal valuation in 1919 of any piece of property, whether it be improved real estate or a public utility is, fundamentally, the total cost of production of that property under the conditions of material prices and wages in 1919.

Purchasing Power of the Dollar

Another element of confusion has arisen in the minds of some in the attempt to draw a distinction between the purchasing power of the dollar and the value of the dollar. It has been stated that the purchasing power of the dollar measured in commodity prices has been cut in half, but the value of the dollar, which should be measured in terms of the wealth of the country, consisting of real and personal property, has not risen. On the basis of this distinction it was argued that prices must fall in order that the purchasing power of the dollar might become commensurate with the value of the dollar. It appears to be an economic fallacy to draw such a distinction. John Stuart Mill defines values as follows:—

"The value of a thing is its general power of purchase, the command which its possession gives over purchasable commodities in general."

In other words, the value of the dollar is the purchasing power of the dollar. Furthermore, contrary to the argument outlined above, prices have remained high and rents and property valuations have been increasing since the time the statement referred to above was made.

The owner of a house and lot may state to the tax assessor that the value of his property is $10,000. In making a

*Abstract of prepared testimony submitted to the Public Utilities Committee of the Chamber of Commerce of the United States.

statement of his assets and liabilties for the purpose of securing credit he may place the value of his property at $15,000. In his own mind he realizes that these valuations are more or less fictitious, though perhaps justified by custom. However, if he knows that the price which he can get for the property is $12,000, he knows that the actual value of the property is $12,000.

In connection with valuations of public utilities and the fixing of rates, although the basic principle which applies to the price of commodities and wages of labor and valuation of real estate constitutes the standard of normality, it is fully realized that, in practice, restrictions, legal and otherwise, operate to modify the application of this principle. However, it is evident to all that so long as these properties are owned and operated by private interests the return must ultimately be in proportion to the cost of production of that which is sold to the public. When operated by the public through government officials, if the rates paid for the service are not sufficient to cover the costs, the deficit has to be paid out of public funds.

It has been pointed out above that the curve for the fluctuation of prices of any particular commodity covering a long period of years, is so erratic that it is impossible to define from it either a "normal" price of the commodity or a "normal" rate of increase in price. However, if the curve representing the average of prices of a great number of basic commodities be drawn, the fluctuations are much less marked than those of any particular commodity.

Prices and productions costs, which constitute the norm of prices, are measured in terms of money. Wages and the cost of living, which is the norm of wages, are measured with the same yardstick, money.

A chart, covering a period of 46 years in the United States, shows that the curve of the price index for basic commodities keeps very close to parallelism with the curve representing the stock of legal tender in the country.

Early in March Professor Fisher's paper entitled "The New Price Revolution," was published by the Department of Labor. Owing to the fact that this was probably the first announcement to the public that prices would not fall, the statement contained in the paper commanded universal attention. This paper pointed out as the cause of the new price level the increase in the amount of money and credit instruments in the civilized world.

Professor Fisher's statement was followed a month later by a bulletin of the Division of Public Works and Construction, "Development of the Department of Labor," which briefly summarized all those facts concerning the records of foreign prices during the war period, the experience of the Civil War, and the war history of prices of basic commodities in this country, which had a bearing on the present situation. These facts were strictly in accord with Professor Fisher's announcement.

Present Price Level Accepted

During the past few months there has been evident a growing tendency on the part of the public to accept present prices and to wait further only for some assurance that prices would not fall.

The investigating committee appointed by the Illinois State Legislature in its report published May 6th, stated definitely that all the facts it had learned concerning wages and production costs and prices were in accord with the theory that a new price level had been established. As evidence of its complete acceptance of this fact, the legislature immediately authorized the letting of contracts for 650 miles of roads.

The growing volume of building operations throughout the country indicates that the public has largely given over its policy of waiting. The Department of Labor is daily in receipt of statements from leaders in business and finance attesting the correctness of the statements it has published concerning prices.

The Federal Reserve Bulletin for May states:—

"The underlying and most general factor tending to sustain the present high level of values is the credit and banking situation inflated as it is throughout the world. So long as the condition of inflation referred to continues to exist as at present, it must be expected that reductions of price will occur slowly as a result of changes in the demand for and supply of commodities. This will in some cases bring about reductions in the levels of values, but in others will produce corresponding and offsetting variations in the opposite direction. Prices will thus be subject to temporary oscillations, but in order to bring about any broad and far-reaching readjustment affecting the relationship of all commodities to the unit of purchasing power, inflated credit conditions must be eliminated, and the business community must be placed upon practically the footing in relation to credit and money which it is normally to occupy."

One of the factors that has tended to delay building operations has been the tendency on the part of bankers to refuse advances of money on the basis of valuations computed in terms of present prices of materials. It is hoped that the statement of the Federal Reserve Board will influence the bankers to pursue a more liberal policy.

Maximum Level Not Yet Reached

According to figures of the Bureau of Labor Statistics, the maximum level of wholesale prices of basic commodities was reached in September, 1918, the index figure being 207. This figure is based on the average for the year 1913 as 100. The index figure for the month of February was 197, for the month of March it was 200, for the month of April it was 203. Weekly quotations continue to show more commodities advancing than declining. Thus it is seen that the price level is again within hailing distance of the maximum. The question to-day is not whether prices will fall or how much they will fall; it is rather, how much higher will they go? The principal commodities that have advanced recently are foodstuffs. Although there is a surplus in this country, there is a world to be fed; and the world supply is short. Mr. Herbert Hoover has been quoted as stating that wheat would probably go to $3.50 a bushel if all restrictions were removed. The cost of living is still increasing and the dollar is still on the decline. The problem is to arrest this decline in the purchasing power of the dollar.

People want to know to-day what future prices are likely to be. It is impossible to prophesy, but it is possible to view facts that will have a bearing on future prices. From these facts it may be possible to indicate future price tendencies.

It took 13 years after the Civil War for wholesale prices to get back to the pre-war level. The circumstances of that period were much more favorable for price reductions than they appear to be at the present time. As compared with the war just ended the Civil War was a purely local affair.

The reason why the present situation has been so difficult to understand is the fact that it is a world-wide phenomenon. The scope of the economic changes has been as wide as the war itself. In January of this year the Bureau of Labor Statistics' index figure for wholesale prices of all commodities showed an increase of 102 per cent. over the year 1913. At the same time the price level in England was 117 per cent. higher than in 1913; in France it was 249 per cent. higher. It is a significant fact that France, which showed such a marked rise in the price level, resorted to inflation to a much greater extent than did either England or the United States. In England and in America it has been considered wise to pay a large proportion of the expenses of the war through the levying of heavy taxes, thus minimizing the necessity for extension of the public debt and the inflation of currency. In those countries where it was considered expedient to avoid high taxation and to resort to inflation, the people are now paying the piper through the high prices they are obliged to give for the necessities of life.

Whether you believe with the majority of economists that the price level is the result of the amount of money, or whether you agree with the minority that the quantity of money accommodates itself to the price level, the present condition of world-wide high prices accompanied by a world-wide increase of money and credits, must be considered. Either prices in the future will be less because of a contraction in the amount of legal tender, or lower prices in the future must be accompanied by a decrease in the amount

of legal tender. Hence the problem of future prices depends upon the solution of the financial problems and a solution of that can not be wholly controlled by any one country.

Lord D'Abernon, an eminent British financier, has been quoted as follows:—

"If there were to be any attempt to-day to bring about a rapid return to the gold currency basis of 1914 it would almost double the weight of the world's indebtedness and would certainly lead to the bankruptcy of many nations. The governments which have borrowed cheap money would, in the case of contraction, have to repay with dear money. Individuals who have borrowed cheap money would have to pay back with dear money. It is extremely unlikely that the governments of the world can be reasonably expected to decrease appreciably the world inflation within a brief period of years."

Condition Not to be Avoided

The conditions that have brought about inflation and the rise in the price level in this country could only have been avoided if all trade relations with Europe had ceased at the outbreak of the war. What has happened has been that we have shipped enormous quantities of goods to Europe. These goods have not been used in production, but have been consumed or destroyed. We have received in return, not goods, but money. These transactions, in the aggregate, have approximated $15,000,000,000. Before the war this nation was indebted to Europe to the extent of $6,000,000,000. We are now Europe's creditor to the extent of $9,000,000,000.

A serious problem at the present time is concerned with the conditions surrounding future trade relations with foreign countries. If America continues to ship goods to Europe, receiving in return only money or promises to pay, there is danger that the disparity between the amount of commodities and the amount of money in this country will continue to grow, resulting in a level of prices even higher than that obtaining at the present time. In view of this, some people think to-day that it may become advisable to restrict exports to such an extent that they may be paid for in commodities rather than in money. Such a regulation could scarcely be put into effect all at once. It might not be practical at all. It would appear, however, that Europe's debt to us must ultimately be paid in goods.

Any consideration of future prices must necessarily involve a consideration of the probable tariff program. Without going into the controversial aspects of this subject, it is well that these phases of it which are likely to affect prices be noticed here. It is a serious question whether it is desirable that a tariff schedule be framed in such a way that we shall continue to ship goods away and receive in return only money or promises to pay. What used to be considered a favorable balance of trade, may not be considered so favorable in the future. The ideal condition in foreign trade is the exchange of commodities for commodiites, money being used merely as that which facilitates the exchange. It is true that it would not be desirable to have foreign goods sold in this country in such a way as to demoralize our markets. It is none the less true that we do not want further increases in our stock of money to such an extent that its purchasing power will continue to decline.

A Serious Problem

This problem is engaging the serious attention of some of the best informed leaders in business, economics and statecraft. It is to be hoped that their reasoned opinions will have a great influence on our future tariff policy. Even though past tariff policies may have been successful, any new policy must be framed after thorough consideration of a large body of new facts. A wise program can not be expected if it is made solely as a compromise between the claims of short-sighted, selfish interests. It can not be expected if the problem is viewed only in the light of before the war.

There are many far-sighted, thoughtful men among our leaders of business and our public men. There are men expert in this intricate subject among our practical economists. It is to be hoped that the ideas of these groups will prevail.

Although foreign trade relations have been so largely responsible for the conditions we face at present, and though these relations may be of great importance in the future, it is possible to concentrate too much upon the problems they involve. These problems can not be settled at once. France has been obliged to await the settlement of the Peace Treaty, and has deemed it expedient to place drastic restrictions on imports during the waiting period. Great Britain has raised the barriers against foreign goods for the duration of such time as is necessary to get her industrial house in order. The period of readjustment in Europe must be necessarily prolonged.

In the meantime, should the people of the United States sit idly by and watch their dollars shrink? Must prosperity wait until foreign markets are opened to us? When the wheels of American industry are turning and every able-bodied worker has a job that brings him a substantial wage, there is a pretty extensive market for American goods among the 110,000,000 people of America. The best way for Americans to set about arresting the shrinkage of the dollar is to produce more goods, thus remedying the existing disparity between commodities and money.

Prices of Building Materials

The shortage in the United States has been estimated at 1,000,000 houses.

At the beginning of the year the building of homes was urged on the grounds of patriotism. At present, it is an absolute necessity that they be built to fill an urgent need. Furthermore, in the light of present information concerning prices, it can be shown that money spent on building is money well invested.

Considered in relation to prices prevailing in the year preceding July, 1914, building materials are cheaper now than most other commodities. By the end of 1918 lumber had advanced 73 per cent. above the pre-war level; mill prices on Portland cement had risen, on the average, 74 per cent.; f.o.b. plant prices on mineral aggregate (sand, gravel and crushed stone) had risen, on the average, 73 per cent.; building stone, on the average, 64 per cent.; common brick, 92 per cent. The building materials group (not including any metal products) rose 84 per cent. Compare this with a rise of 113 per cent. in all other commodities, and with a rise of 116 per cent. in the group of farm products. The cost of construction of buildings on the average has increased about 62 per cent.

Little evidence is in sight pointing to a decline of prices in general. There is even less likelihood of declines in prices of building materials. The index for the group was the same for the first quarter of this year as for the last quarter of 1918. Slight declines in some materials have been offset by slight advances in others. As a group the prices have been practically stabilized.

In the nature of things, prices of building materials fluctuate less than the prices of those commodities which are consumed from day to day, such as foodstuffs and textiles, and of those commodities such as the metals, which furnish the raw materials of industry. During the Civil War building materials advanced less rapidly than did other commodities and they failed to reach the high levels of other commodities. In fact they remained above the general level of all commodities until 1874. If building materials, instead of fluctuating in price, had declined from the high point of January, 1865, at a uniform rate of 4 per cent. per annum until 1874, they would have reached their actual 1874 level, which was the general level of all commodities for that year.

Not Likely to Decline

A decline of 4 per cent. per annum in prices of materials would probably not involve an annual depreciation in value of a building of more than 2½ per cent. The fact is that present conditions do not indicate that the next few years will see declines in building material prices amounting to as much as four per cent. a year. It is more than likely that building materials, on the average will not decline at all for a considerable period. Present indications are that building

FLAT RATE vs. METERS*

Comparison Between Operating Conditions Under the Two Methods of Charging for Water Consumed—Flat-Rate System Unjust to Consumers—Meters Profitable

By C. E. Abbott
Water Works Superintendent, Tuscaloosa, Ala.

THERE has always been some controversy as to the relative merits of conducting water works systems on a flat-rate basis and an all-meter basis, with conditions otherwise the same, and as to whether the benefits to be derived warrant the installation of the all-meter system. The owners and operators are practically unanimous in support of the meter system, while the consumers uniformly contend for the flat-rate basis; and this fact alone tends to show upon whose side the benefits of the meter system lie.

Of course, no criterion can be established for the entire country from statistics gathered in any one locality and, furthermore, it would be foolish for any one man to undertake from his own experience to prescribe the best operating methods for localities other than his own and operating under conditions with which he is not familiar. I have been manager of the water works system at Tuscaloosa, Ala., for about eight years. During this time the plant there has been operated first upon a flat-rate basis and later upon a practically all-meter basis, and I am therefore in position to give facts and figures by a comparison of which the many advantages of the meter system can be easily seen. However, I certainly do not wish to be regarded in the light of trying to tell other managers and superintendents how to run their business, or to insinuate that I know it all, or any more than any one else; but, having operated my plant under both systems and had opportunity to observe carefully the results of both operations, it has occurred to me that probably the figures covering these operations might be of interest to other operators who perhaps at this time find themselves under similar conditions as we were when we contemplated the change from the flat-rate basis to the meter basis.

From the Operator's Viewpoint

There are many advantages of the meter system over the flat-rate system that need no comparison to establish their validity. One of the foremost of these is the great injustice, to the consumers themselves, of the flat-rate system. Upon this slack basis one consumer may pay a stipulated amount for his water—based probably upon the number of openings—and probably use 5,000 cubic feet of water within a given time; while another consumer, with the same number of openings and paying the same basic amount for his water, could use 10,000 cubic feet of water within the same time and with no additional cost.

However, being a manager of a plant, of course, I am concerned chiefly with the operator's side of the matter, and it is the benefits and advantages to be derived by the operator himself that I propose to show in making a comparison of the statistics set out herewith, representing the operation of our plant first upon a flat-rate basis and latter upon a meter basis. Of course, the points of greatest concern to the operator are: Increasing the general efficiency of his plant, cutting down the amount of water to be pumped, cutting down the amount of fuel consumed—with the consequent decrease in operating expense—and increasing the revenue.

In 1911 the plant of which I am manager was operating upon a flat-rate basis. We commenced installing meters in the fall of 1913, with the idea of metering the entire system, which was practically completed in 1915. Beginning with the year 1916 the plant was operating upon practically an all-meter basis. Therefore, by a comparison of the statistics covering the operation during these two years, the effect of the installation of the meter system can be shown; and by this comparison I propose to show how the amount of water pumped per day in 1911 under the flat-rate basis was decreased in 1916 under the meter basis by about 27%, notwithstanding the fact that there was an increase in the number of consumers in 1916 of about 65%, and how the amount of coal consumed in 1911 was decreased by about 170% in 1916, and the operating cost decreased proportionately.

*Excerpts from a paper read before the annual convention of the American Water Works Association at Buffalo.

Operating Conditions in 1911

The general conditions under which the plant was operated in 1911, and the equipment, were as follows:—

The power plant is situated upon the banks of the Warrior River, about three miles above the city of Tuscaloosa, Ala. The plant is situated upon an incline—the settling basin being above the plant and the water flowing by gravity through slow sand filters to the clear-water basin below the plant. The water was pumped from this clear-water basin to a stand-pipe in the city—the tank having a capacity of 125,000 gals. and an elevation of 100 ft. The pumps were operated twenty-four hours a day, working against a pressure of 165 lbs. at the plant. The actual equipment consisted of three 72-in. by 16-ft. return tubular boilers; two horizontal compound, non-condensing Worthington pumps—alternating in operation weekly. The cylinders were:—High pressure, 16 ins.; low pressure, 25 ins.; water plungers, 11 ins.; stroke, 15 ins.; rated capacity, 24 gals. per stroke. The water pumped in 1911 is figured on the delivery of these pumps, allowing 10% for slippage.

The figures covering the operations during the year 1911 are as follows:—

Number of consumers at end of 1911:—	
Flat rate	927
Meter	42
Amount of water pumped during entire year	317,335,980
Average amount of water pumped daily	869,413
Number of tons of coal used during the year	3,285

Cost of coal $2 per ton.

General Conditions in 1916

The general conditions under which the plant was operated in 1916, and the equipment, were as follows:—

The operating conditions in 1916 were the same as in 1911, with the exception that a new reservoir had been built within one-half mile of the power plant. It is 62 ft. high and 75 ft. in diameter, constructed of reinforced concrete. This reservoir was planned and built by Morris Knowles, of Pittsburgh, Pa., and is a magnificent piece of engineering work. Also a new high-service pumping engine was added: Type, Myer; gear flywheel; high pressure cylinder, 14 ins.; low pressure cylinder, 30 ins.; water plunger, 10¼ ins.; stroke, 24 ins.; condensing; rated capacity, 30 gals. per stroke; manufactured by Laidlaw Dunn Gordon Company. The amount of water pumped in 1916 is figured on the delivery of this pump, allowing 5% for slippage. The number of pumping hours was reduced in 1916 to an average of 10 hours per day.

The figures covering the operations during the year 1916 are as follows:—

Number of consumers at end of 1916:—	
Flat rate	190
Meter	1,414
Amount of water pumped during entire year	230,779,985
Average amount of water pumped daily	632,274
Number of tons of coal used during the year	1,215

Cost of coal $1.95 per ton.

Comparisons, 1911 and 1916

Total number of consumers in 1911	969
Total number of consumers in 1916	1,604
Numerical increase in number of consumers	635
Representing an increase of 65% plus.	
Amount of water pumped during 1911	317,335,980
Amount of water pumped during 1916	230,779,985
Numerical decrease in gals. pumped	86,555,995
Representing a decrease of 27% plus.	
Number of tons of coal used during 1911	3,285
Number of tons of coal used during 1916	1,215
Numerical decrease in number of tons	2,070
Representing a decrease of 63% plus.	

All the above figures are taken from the records of the City Commission of Tuscaloosa, Ala., and can be verified upon inquiry.

Best Check on Operation

From a standpoint of efficiency, and in order to check the operations of the plant, it is essential that the operator account for, so far as is possible, all the water that is pumped; and it is unquestionable that the meter system provides the best method for this. However, notwithstanding all the benefits derived from the employment of meters, even where the meter system is employed, certain conditions arise in which it is not practicable to use meters. It will be noted that while employing the meter system almost entirely, we still have 190 consumers receiving water on a flat rate. This condition arises from the fact that these 190 consumers live outside the sewer zone and have each only one opening on the premises, and twenty meters placed on consumers under identically the same conditions show that 50% of the minimum allowed under the flat rate is never reached.

With the meter system in operation during the year 1916 we were enabled to account for 85.8% of all the water pumped during the year. These figures would be higher but for the fact that we had no way of accounting for the water used in fighting fires, and the amount used in street flushing, sprinkling, etc., is purely an estimate based upon the capacity of the tank, and the estimate is in fact considerably below the amount of water actually used for these purposes. The figures in substantiation of this are as follows:—

Where the Water was Used

Total meter reading for domestic consumers ..	114,186,477
Total meter reading for mannufacturers, etc. ...	59,144,425
Total meter reading for filter wash water	9,552,660
Total meter reading for schools	2,920,460
Estimated amount used in street sprinkling, etc.	11,182,000
Total amount of water accounted for by records	196,986,022
Total amount of water pumped during year ..	230,779,985
Water unaccounted for	33,793,963

Representing a percentage of only 14.2% of the total amount pumped as being unaccounted for.

Lockwood, Greene & Co. of Canada, Ltd., industrial engineers, have opened an office in Montreal. E. G. Horne, formerly of Grant & Horne, contractors, of St. John, N.B., is the manager. The head office of the parent company, Lockwood, Greene & Co., is in Boston.

The Association of Canadian Building and Construction Industries called a meeting of its national council to be held last Monday in Ottawa in order to meet representatives of the government and of organized labor, for a general discussion of the labor situation. About seventy-five labor delegates and approximately an equal number of employers were expected to be in attendance.

The question of a general sewerage system for the municipalities of St. Lambert, Lougueuil, Greenfield Park and Montreal South, has been before the Quebec Public Utilities Commission. Messrs. Lea and Duchastel, engineers appointed to prepare plans, reported that there was a difference of opinion between the municipalities as to the location of the outlet and the engineers recommended that it be placed about 1,600 ft. out in the river, just below the government wharf, at a point known as St. Antoine's Creek. F. W. Cowie, engineer for the Harbor Commission, objected to this location on the ground that it might interfere with the future plans of the Commission, and that the situation is one where the outlet would be menaced by ice. Objections to the site proposed were also made by representatives of the municipalities interested. The engineers were instructed to continue making tests as to the current and ice conditions, whether the outlet should be temporary or permanent, and also as to whether it would be advisable to construct the sewer of greater strength than was at first proposed.

BOND PREMIUMS ON GOVERNMENT CONTRACTS*

THE form of "cost-plus" contract used by the construction division of the United States War Department during the war provided under the heading of "Cost of Work" for reimbursement of the contractor's actual net expenditures. Among the various items was the following:

"(h) Such bonds, fire, public liability, employer's liability, workmen's compensation and other insurance as the contracting officer may approve or require."

Article IX. provided that:

"The contractor shall, prior to commencing said work, furnish a bond with sureties satisfactory to the contracting officer."

Notwithstanding these provisions, the comptroller of the treasury has recently held that the form of cost-plus contract in use by the construction division does not authorize the reimbursement to contractors of the cost of premiums on their bonds. This ruling has been adhered to in the face of strong objections by the chiefs of the construction division.

Association Secures Legal Assistance

Upon inquiry of representatives of the construction division, it is ascertained that it is quite certain that all contractors having unsettled contracts for work under that division and money due them under such contracts will now have deducted from any balance due them the sum of all payments heretofore made to them covering reimbursement of premium on bonds. This will probably include not only their unsettled contracts but such payments made upon other contracts of this class upon which settlements have already been made. It is not possible to say whether those who have no current construction contracts will be called upon to refund all such sums heretofore reimbursed to them. This will depend upon the discretion of the disbursing officers of the war department and the orders of the accounting officers of the treasury.

This matter is one of wide importance to contractors and accordingly the officers of the Associated General Contractors of America have taken up the subject for conference with King & King, attorneys, Washington, D.C. As a result of very careful consideration, the following suggestions are made:—

If the amount of premium bonds already is deducted from moneys otherwise due upon current contracts, the contractors should accompany the voucher covering any such payment and showing such deduction with a letter containing substantially the following language:—

"It is to be understood that in accepting payment evidenced by the attached voucher under our contract of ..... for constructing ..... we do so without in any wise waiving our legal rights to full reimbursement under the terms of our contract of all sums paid by us as premium on bonds. We expressly reserve our rights to reimbursement of all sums paid by us on such account."

This letter should be pasted to the voucher.

Refuse Demands for Refunds

Those who are called upon to refund any payments of the kind noted should decline to do so abolutely and leave the government to take such action as it may deem advisable looking to a recovery.

The attorneys named have given us their opinion that the contracts entitle the contractors to reimbursement of these premiums, that the deduction is unlawful, and that it can be recovered by future proceedings in the treasury department or before the court of claims.

The opinion of the comptroller above referred to was given as an advance opinion to several disbursing officers. This will govern the action of all disbursing officers for the future, but it is not conclusive even in the comptroller's office. The matter can be brought before the comptroller again upon a claim duly presented by any contractor. This claim must be filed with the auditor for the war department and will

*A circular letter mailed to members of the Associated General Contractors of America.

be disallowed by him and then appealed to the comptroller. The comptroller will then hear legal argument upon the merits of the question. The opinion already rendered will be considered by him as prima facie correct, but he will not hold it to be finally binding upon him, if convinced to the contrary by any arguments then presented to him. There are numerous precedents for the comptroller reversing, in a claim thus brought before him, an advance opinion rendered to a disbursing officer.

Will Conduct Test Case

Should the comptroller decide this test case favorably, the other claims will be paid. If the comptroller adheres to his unfavorable decision, a test case can then be taken before the court of claims. If the court of claims decides in favor of the contractor in the test case, the comptroller will probably reverse his decision and allow other claims of the same nature, if they have not already been brought before him and adversely decided.

It is also possible to test this question by insisting upon a suit being brought against a contractor by the United States. It may be thought best to take this course, but at present it is thought best to make the test by a suit in the court claims.

It is not probable that any contractors will be pressed for payment of premiums already paid to them under settled contracts unless a decision should be rendered by the court of claims adverse to them. Such a result is not expected. If that is adverse, there will still be an opportunity for defense to such claims under the provision of Article IV. of the contract, providing that the monthly statement of costs and "all payments made thereon shall be final and binding upon both parties hereto."

Independent Action Not Desirable

This association expects to take up this matter as an association matter on behalf of the contractors interested. Nearly all of them are already members of the association and it is hoped that all others interested will join the association in order to bear their fair share of the movement. It is very important that contractors should leave the handling of this matter to the association, as independent action may interfere with the orderly handling of the test case in the manner above outlined.

ADVANCE IN BOOK PRICES

ANNOUNCEMENT is made, to take effect immediately, of an advance of $1.00 per volume in a number of $5.00 handbooks published by the McGraw-Hill Book Co., of New York City. The company states that the increase from $5.00 to $6.00 is necessitated by the steadily increasing cost of labor and materials.

Readers are also reminded that announcement was made recently by another very prominent New York publisher, John Wiley & Sons, Inc., that an increase in the prices of a number of their books would go into effect August 20th.

All orders received by *The Canadian Engineer's Book Department* for McGraw-Hill books will now have to be at the new schedule of prices, but all orders for Wiley books received in time for transmission to New York before August 20th, will be taken at the old prices.

Great interest is being shown in Japan in the development of the hydro-electric industry, according to M. Nakamura, of Tokio, an electrical engineer who is travelling through Canada in the interests of his profession. At present, the development of 1,000,000 h.p. is contemplated or under way. The production of electrical equipment is sufficient to care for domestic requirements. Electric heating, which is the department in which Mr. Nakamura is most interested, is proving productive of an unusually heavy demand for equipment, and heating appliances will have to be imported in large quantities, he says.

WATER POWERS OF BRITISH COLUMBIA

ARTHUR V. WHITE, consulting engineer to the Commission of Conservation, recently completed a report on the water powers of British Columbia. This report, which will soon be issued by the Commission of Conservation, estimates the total 24-hour horse-power of the water-powers of that province at about 3,000,000 h.p., in round figures.

Mr. White's report completes the series of water-power reports which the commission in 1910 undertook to publish. The British Columbia investigation was commenced in 1911.

Referring to the difficulties experienced in obtaining the data in the report, and to the conditions affecting water-powers in the province, Mr. White says:—

"The season available for such reconnaissance water-power investigations as were made in British Columbia is comparatively short. One of the chief difficulties encountered is that it is almost impossible for observers to avoid over-recording in their notes the power possibilities of stream observed during high-water. Young engineers are impressed by the quantity of water coming down the rivers, and have not the advantage of having observed the same streams at their low-water stages, nor have they always the knowledge of measurements of the flow of similar streams to temper their judgment.

Power Conditions are Unique

"The conditions affecting powers in the province are unique, and do not closely correspond to those existent in other portions of Canada. This is especially true of the mainland Pacific coast. One cannot but be impressed with the fact that coastal water-powers in British Columbia, which to the casual observer appear to be of comparatively small amount, nevertheless may, when economically and fully developed, yield several-fold the estimate of power, if appraised upon the same basis as similar streams in Eastern Canada. Glaciers, snowfields, and heavy rainfall abound, and, with many storage possibilities, constitute unique factors which contribute to enhance the values of powers. These conditions, on the other hand, emphasize the necessity of special and very careful engineering investigation and expert handling."

Power site tables giving summarized data with regard to the various water-powers, are given in the report, which says, in reference to these tables:—

"Owing to the topography of British Columbia and the relative small extent of territory covered by detailed topographic and hydrometric surveys, it is practically impossible to make anything like a close estimate of many of the water-power possibilities. Both the confines of the watersheds of many of the available streams and their run-off are unknown. In such cases any figure purporting to give the available amount of power is at best only an estimate indicating possibilities.

Three Million Horse-Power

"The power tables contain summarized statistical data regarding the water-powers. It is not practicable to indicate any details of information upon which the tabular estimates are based, but all available data have been used. Effort has been made to keep on the conservative side, and totals for the province, based on the tabulated estimates, can only fairly be compared with estimates for other large territories by taking into account the conservative character of the deductions. . . . Estimated quantities are on the basis of 24-hour horse-power, 80 per cent. efficiency. If comparison is made with other estimates of horse-power giving theoretical quantities, then our estimates should be increased 25 per cent."

Following is the estimate of the powers in the province, which has been divided into districts for the purposes of the report:—

	24-Hr. Power.
1. Columbia River and tributaries (north of the international boundary): This comprises the portion of the province lying between its eastern boundary and the watershed of the Fraser River	610,000 h.p.

2.	Fraser River and tributaries: This includes practically the entire area of the great interior plateau	740,000 h.p.
3.	Vancouver Island	270,000 h.p.
4.	Mainland Pacific coast and adjacent islands (except Vancouver Island): This includes all the rivers north of the Fraser, which drain into the Pacific	630,000 h.p.
5.	Mackenzie River tributaries (a rough estimate made for inclusion in this summary)	250,000 h.p.
	Grand total,	2,500,000 h.p.

The above total includes about 250,000 h.p. for plants already in operation, but it does not include about 400,000 h.p. for power possibilities on streams like the Fraser, Thompson, Skeena and Naas Rivers on which, because of the proximity of railways or possible interference with the salmon industry, economical development cannot be considered under present conditions. Also there is still considerable territory, especially in the northerly portion of the province, which it has not been possible to investigate fully. These areas may yet disclose a considerable amount of power, says Mr. White.

HOW TO REDUCE RISKS IN EARTHWORK*

By Halbert P. Gillette

FEW classes of construction are so difficult to control economically as earth excavation. Rainy or freezing weather may completely upset the best-laid plans and cause a severe financial loss. Usually most of the working gangs are common laborers, quite irresponsible, quitting at the slightest provocation, often with no provocation.

The character of the earth itself may vary greatly from week to week, or even from hour to hour. The length of haul is seldom constant, even for one day. Small wonder, then, that no ordinary class of contracting is more hazardous than earthwork.

Experience Necessary in Estimating

The first great risk is taken when the estimate is made as to the classification of the excavation. Here it is that experience counts so much in favor of an older man, and lack of experience hits a younger man so hard. But a young contractor is not necessarily without means of self-protection. He can employ an experienced superintendent, he can dig test-pits and make earth soundings.

When I first went into the contracting business I soon learned never to bid on excavation until I had "prospected" the job pretty thoroughly. It is surprising how much can be accomplished in a short time in this manner.

Sounding with rods is an expeditious way of ascertaining the depth to ledge rock or to hardpan, and it will also disclose the existence of boulders. But in an unfamiliar country it often is necessary to dig test-pits or small wells, so that the toughness of the earth can be judged by observing the resistance to a pick.

Often there is insufficient time to prospect the ground thoroughly. Then, if the work is in a section where your experience has been limited, don't bid at all if the earthwork is extensive.

Prospecting for Facts

Some years ago, a firm of young contractors in New York City asked me to assist them in estimating the cost of a large job of excavation in New York State. The cuts and fills were heavy, and the engineers had made no soundings. The engineers had estimated that the excavation would be 75% solid rock and 25% earth. After walking over the line, I asked one of the contractors what he thought of the "three to one" classification the engineers had made. He replied that it seemed to be "any man's guess," but that he presumed the engineers were approximately right, as they had been engaged for months on the surveys and in planning the construction. Had he known more about common engineering practice, he would have had little faith in that guess as to classification. I explained to him that about the last thing that the average engineer does on such a survey is to estimate the classification, and that then he usually guesses, often wildly. "Well," said the contractor, "we want to bid on the job, and it's too late now for us to do more than guess also." He was surprised when I assured him that in the two days remaining before the bids would be opened, we should be able to estimate pretty accurately what percentage of the excavation was solid rock. Since many of the cuts were 50 to 60 ft. deep, and quite long, it looked like an impossible job to do much sounding in two days; as for adequate test-pit sinking, that was impossible.

Boulders, Not Solid Rock

Jutting from the surface of the earth at frequent intervals was rock (gneiss) that appeared to be ledge rock, and it was this appearance that had led the engineers to estimate 75% solid rock. I pointed out to the contractor that ledge rock in southern New York State is usually grooved in a north and south direction as a result of the grinding action of ancient glaciers; but that none of the outcropping rocks that we had seen on that job were grooved or scratched in that regular manner. Hence they probably were boulders. There were other geological facts that led me to the same conclusion, but it remained to prove the inference beyond doubt.

I had noticed along the line several wells that supplied water to farmers, and these, I believed, would be rather deep-dug wells—real test-pits for our purpose. We were able to find the men who had dug some of these wells, and to learn from them that they had dug 50 to 80 ft. without striking solid rock, and that they had encountered few boulders.

In order to confirm this testimony, we put several small gangs of laborers at work sounding with rods. The results of that sounding showed that there was no ledge rock at all in any of the cuts. The subsequent excavation proved this conclusion to be substantially correct.

Naturally, these contractors bid a fairly stiff price on earth and very low on rock, and were the lowest bidders.

Adequate Plant Reduces Weather Risk

In estimating both the classification of excavation and the toughness of the materials, any nearby cuts should be examined; and local men who have done any excavation should be interviewed.

Having secured the job, it is important to reduce the bad weather risk by starting excavation as quickly as possible, and by using enough plant to rush it through before the autumn rains start. Here it is that the inexperienced contractor is apt to err. He may not order all his plant until he signs the contract; then he usually orders neither enough plant nor spare parts. Delays occur in getting the plant on the job, and several weeks of good weather may be lost before the work is going "full swing." Even then the "swing" is not "full" enough because of pennywise attempts to save money on plant investment.

I recall that a certain contractor on the deepening of the old Erie Canal in 1896 made a profit where his neighbor contractors lost money, simply because he brought, begged and borrowed a lot of equipment so that he was able to finish before the ground froze.

Have a liberal surplus of plant capacity, for surplus plant is the best investment on an earth-moving job.

Fit the Plant to the Job

The next important risk to eliminate is the risk of using a relatively uneconomic method or machine. There is no better way of reducing this risk than by having daily, weekly and monthly reports of the yardage moved by each

(Concluded on page 41)

STANDARDIZATION*

By Guilliam H. Clamer
Vice-President, Ajax Metal Co., Philadelphia, Pa.

THERE was a time when the candle maker and the candlestick maker each made their wares to suit their own inclinations. As a consequence, seldom did the candle user find that the candle would fit his particular candle-stick. Time, in the days of candle illumination, was, however, not so precious as it is to-day, and a little more or less time consumed in shaving down its end, if the candle was too large, or if too small, in whittling a wedge to support its base. was of little consequence

It nevertheless finally dawned upon these two classes of manufacturers that if they were to get together and standardize the size of the candles, and also make the sockets of their candle-sticks of such dimensions that the candle would properly fit, time would be saved, annoyance prevented and convenience promoted. This is one of the early examples of standardization and it has been referred to by Sir Joseph Whitworth, one of the early workers in the field of standardization, and the introducer of the series of screw threads known as the Whitworth standard.

Standard-Gauge Railway Construction

There was a time, not so long ago, when there was no United States standard track gauge for our railroads. Without standardization of track gauge it was impossible for the equipment of one railroad to be used on another. It has only been through standardization of track gauge that interline transportation has been made possible. We now travel in the greatest comfort from one end of the country to the other without a change of cars. A freight car may be loaded in Maine and without transfer of its cargo arrive in San Francisco or Key West. In fact, it may even be loaded on a barge at Key West and transferred to any part of the Island of Cuba over United States standard-gauge track.

At the present time very active progress is being made in railroad building in South America and Central America, and very shortly activities in the line of railroad building will be again resumed in Mexico; and it can be confidently expected that a Pan-American Railroad, extending from any part of the United States to Argentina, a distance of ten thousand miles, will become a reality. It is unfortunate, in this stupendous undertaking, that all sections of this railroad should not be of standard gauge. A large part of the trackage in the southern countries, as at present built and under contemplation, is of gauge which differs from our own.

I do not believe that there is one single effort which can be taken in bringing countries of the western hemisphere into closer relationship than the building of a standard gauge railroad over this entire distance.

Pipe, Screws, Bolts, Nuts, Etc.

There was a time, within the memory of the present generation, when there was no such thing as standard pipe sizes or threads; and, even more recently, when there were no standard machine screws. Each manufacturer had his own special threads. Selfish interests were so strong and the vision so narrow that great opposition on the part of the manufacturers prevailed against standardization of screw threads. Each manufacturer wished to compel the user of his machines to come to him for repair parts. He did not realize that his business interests were impaired if a user of his machine suffered inconvenience and perhaps financial loss by the shut-down of the machine because of the necessity of sending to the factory to get the necessary repair part.

There is at present before congress a bill which proposes to extend the life of the commission to standardize screw threads, created under the act of July 18th, 1918. Governmental action has in the past legalized other standards. The first attempt at standardization of screw threads, bolts, nuts, etc., was made in 1864 by a committee of the Franklin Institute of Philadelphia. This committee recommended the adoption of the system known as the United States Standard which was devised by William Sellers. In 1906, the Association of Licensed Automobile Manufacturers adopted standards for automobile screws and nuts, and a year later the American Society of Mechanical Engineers accepted the report of its committee on standard proportions for machine screws. The screw threads adopted by this society differ only in very minor details from the Sellers or U. S. Standard. This report specifies tolerances and includes standards for taps, special taps, special screws and screw-heads of various types. In 1912, the Society of Automobile Engineers enlarged their number of standards.

An act of congress in 1893, established a standard gauging system for sheet iron and steel. This was a purely arbitrary standard. Other arbitrary gauges are in use for wire and drills as well as for sheets. The only rational system is the decimal system in which the gauge number is expressed in thousandths of an unit.

There is a long list of further standardization work which has had its stimulating effect upon industrial progress, but these few illustrations I have given are sufficient to emphasize the importance and magnitude of this line of endeavor.

Only within the present century has standardization in manufacturing processes, methods and practice been seriously pursued and so-called scientific management inaugurated. Industrial progress owes much to the adoption of such standardization. In the automobile industry particularly we have out-classed the world because of such standardization. The adoption of standardization to shipbuilding during the war has put America, within two years time, in the first rank in this industry.

Quantity production can be realized only by reason of such standardization, and at the time of the signing of the armistice, quantity production in the manufacture of our airplanes was well under way and history will no doubt reveal the fact that this was quite instrumental in bringing our enemies to the realization that it was futile to further pursue the war.

Conservation Division, War Industries Board

During the war conservation of our resources became an absolute necessity and the work of the conservation division would have had far reaching effect had the war continued. The conservation division was organized to perform the function, which was expressed by the president in his letter to Mr. Baruch, as "the studious conservation of resources and facilities, by means of scientific, industrial and commercial economies, to meet war requirements."

The necessity for such standardization, as a war measure, was unquestioned, but just how far such standardization, in peace times, would be economically advantageous or economically detrimental, is speculative. Consumers are willing to pay for selection and for the gratification of their individualistic tastes as to style, color, form, etc. It is this fact which, in a very great measure, has resulted in the enormous number of commodities, differing in only slight degree from each other, now being offered on the market. A reference to but a few typical examples of our war-time conservation will be of interest in pointing out the wonderful possibilities in this direction.

Pneumatic tires, reduced from 232 styles to 9; solid rubber tires, 100 styles to 15; steel pens, 700 to 300; china and crockery, from 1,696 pieces to 330; 5,500 styles of rubber footwear discontinued, meaning a yearly saving as follows:—

29,012,600 cartons,
5,245,300 sq. ft. of lumber,
4,795 tons of freight,
1,526,423 cu. ft. shipping and storage space,
2,250,272 lbs. of material that will not have to be dyed,
74,750 lbs. of flour and starch,
30,380 gals. of varnish,
125,300 lbs. of tissue paper,
49,617 days of labor.

*Presidential address at the annual meeting of the American Society for Testing Materials.

Consider such a matter as the method of packing thread. If marketed with 200 yds. to a spool, instead of 100 and 150, there would be saved 5,146,815 ft. of lumber or 365 carloads. The saving in shipping space of finished product is about 600 cars, in wrapping paper 3½ tons, and in twine, 5 tons. Had the yardage been reduced to 100 yds. per spool it would have required over 600 cars to transport the lumber, so that the total saving is 1,200 cars by using the 200-yd. spool.

With these few examples, it can be readily realized what tremendous savings might be effected if a safe and sane policy of standardization was put into effect through co-operative agreements. It means lower cost of production, smaller capital investment, etc., with a greater amount of capital released for more useful purposes.

Research and Standardization

Emerson's definition of a standard is as follows: "That which is established by investigation or authority to be a reasonably attainable maximum of desirability."

Research and standardization should go hand in hand, but the body controlling the former should not also dominate the latter. Research should point out the ideal, namely, the highest standard of excellence which should be approached as nearly as possible by the approved standard. The final specification must of necessity be a compromise between consumer and producer, the consumer demanding the nearest approach to the ideal, and the producer agreeing to that which is commercially possible, cost, rapidity of production, service requirements, etc., all having due consideration.

Standards Often Must Advance

Research bodies should never be satisfied that the ideal which they have set up is final, otherwise practice becomes crystallized and invention discouraged. What if the locomotive of twenty years ago, or even ten years ago, were to have been considered a final standard? What if the standard locomotive or standard cars recently adopted by the U. S. R. A. Committee were to be considered a final standard, or if the automobile of but a few years ago were no further improved upon? Such standardization, if not constantly open for revision, would, instead of benefiting the industries and mankind in general, actually do a positive harm.

Unfortunately, many standards have been adopted without a proper knowledge or without due consideration, and when such standards are once established it is exceedingly difficult, costly and inconvenient to abandon them. The one great shining example of this was the adoption of our cumbersome and unsatisfactory system of weights and measures.

Recommended D.C. for Niagara Power

When the great Niagara Falls power plant was to have been installed, expert opinion was secured to recommend whether direct or alternating current systems should be used. This was at a time when alternating current systems were quite new. Lord Kelvin, a great authority, recommended the installation of direct current apparatus. In the light of our present day knowledge on this subject, just think what a tremendous mistake that would have been. When it was finally decided to install alternating current, Professor Roland, of Johns Hopkins University, was consulted regarding the nature of the alternating current which should be used. After a painstaking investigation he recommended that current be delivered at 25 cycles. It, therefore, so happened that the expert advice that was followed in the installation of that plant resulted in the establishment of a standard for the current supply which has stood the test of time. In such an installation there is involved not only the power plant itself but all the existing circuits and equipments connected therewith, and it may therefore be realized how costly and inconvenient it would be to change, in a case of this kind, from one standard to another.

It frequently pays to adopt new standards, notwithstanding the expense involved, rather than to continue with an old standard which is evidently wrong and inefficient. Many examples exist in machine design, and in the standards adopted by the Master Car Builders' and Master Mechanics' Association and other standardizing bodies which are universally acknowledged as poor; but as the equipment has been built up about such standards and as to change would result in an enormous cost, they are unfortunately continued.

Cost Accounting and Industrial Co-Operation

Some time ago the New York milk dealers asked for an advance in the selling price of their commodity. They were unable to show the actual cost of milk delivered to the consumer and were therefore not in position to substantiate their demands. Investigation revealed the fact that adequate and reliable cost-keeping systems are rare. Some attempts have been made in certain industries to establish standard cost-keeping systems—the American Foundrymen's Association has a committee on the subject. They have retained an expert who acts in an advisory capacity to its members.

The cast-iron stove manufacturers have done the same. It was found that two manufacturers producing an identical line of stoves, exhibited widely different costs for the different types. A certain small type was sold by one manufacturer below the cost price of another, whereas, a larger type could not be produced by this same competitor at the latter manufacturer's selling price. The explanation is simple, namely, they used different methods for distributing costs.

With a standard cost-keeping system within an industry, all would be benefited because all comparisons of the many items going to make up the cost would be upon an equal basis. A most important assistance could be rendered our industries if there should be organized a National Bureau for Establishing Cost Systems, the function of which should be to investigate the accounting systems in vogue in the industries, and to render assistance in the establishing of standard cost accounting.

During the war startling facts were revealed in this connection. The cost, as submitted by different manufacturers, on the same specification were so widely divergent that upon the "cost-plus" basis the government would have been called upon to pay widely varying prices for the same commodity. The need for standardization in this connection is so apparent that the United States Chamber of Commerce at a recent convention passed a resolution favoring a system of uniform cost accounting in each industry. This resolution had the endorsement of approximately 3,000 men representing all lines of commercial and industrial interests, and emphasizes the growing desire and tendency of industrial leaders to do away with the rule of guess and gamble and to establish their industries upon the science of correct and adequate records and account. It is only by such means that the present day gross inefficiencies will become recognized and eliminated. True advancement in industrial management and operation can best come through industrial co-operation; it would be a pity to allow the fruits of the co-operation which was established during the war to be wasted now because of the throttling power of the now generally conceded unwise legislation which was enacted some years ago, namely, the so-called Anti-Trust Laws.

Benefits Capital and Labor

The value of industrial co-operation was well recognized and greatly encouraged by the government during the war. Without such co-operation the wonderful productive capacity of our industrial establishments could not have been availed of to its fullest extent. Through standardized conditions, standardized records and standardized accounting, industries can be brought under intelligent government supervision and control. It would thus only be possible for such co-operation to proceed and be encouraged without doing final harm to the public. In fact it would lead to the decided benefit of labor and of the public as well as to capital.

To emphasize the attitude of the present day in this connection, I will quote a resolution of the United States Chamber of Commerce, recently issued by that body, which so strongly represents our American industries:—

"Resolved: The war has demonstrated that through industrial co-operation great economy may be achieved, waste eliminated and efficiency increased. The nation should not forget, but rather should capitalize these lessons by adapting effective war practices to present conditions through permitting reasonable co-operation between units of in-

dustries under appropriate federal supervision. The conditions incident to the period of readjustment render imperative that all obstacles to reasonable co-operation be immediately removed through appropriate legislation."

International Standardization

Standardization is the keynote to convenience, comfort and efficiency. We are so accustomed to the use of our fundamental standards, weights and measures, expression in language, national currency, postage, etc., that we do not fully realize what the establishment of such standards means to us individually, and to our national prosperity. Were each state to have a different language, a different standard of weights and measures, etc., we would not now be united into a vast and prosperous country. There is nothing that will promote international trade co-operation and good fellowship so much as would the establishment of wise and mutually satisfactory standards, some of which may be classified as follows:—

1. *International Language.*—National jealousies would no doubt prevent the adoption of any of the existing languages, unless the power of the nations now using such language should become sufficiently strong to enforce it. Germany, in her deep-seated plans to rule the world, had done all in her power to establish the German language in schools and colleges of many lands. Had her plans succeeded, the German language would no doubt have been enforced upon the world as it was in Alsace-Lorraine after the war of 1870.

The English language has long been the prevailing language in the world of commerce, and with the now still greater alliance of the Anglo-Saxon races will no doubt be extended. The English language as a standard leaves much to be desired when compared with the ideal; simplified spelling would help materially. The commercial advantages which would accrue temporarily (one generation at least) to the English speaking people of the earth, were the English language to become standardized, would be so great that such adoption would be sure to be frowned upon by all other nationalities. This being a fact, two entirely neutral languages have been proposed; these proposed languages being purely artificial, one knows as Volapük, meaning "world speech," published in 1879, and the other Esperanti, named for its originator, proposed some years later.

Artificial World-Language Needed

The International Congress of Philosophy, which met in Paris in 1900, defined the following essentials with which such an artificial language must comply, namely:—

The language shall serve the needs of daily life and business as well as the requirements of science and learning.

The language shall be so simple that a person possessing an average common school education can acquire it readily.

No doubt efforts will now be renewed toward the establishment of a standard system of expression for world-wide use.

2. *International Religion.*—Two hundred and sixty-eight religious sects, past and present, are recorded. About one-third of the population of the globe are followers of Buddha. Many Christian denominations differ from one another mainly on interpretation of the Bible.

During the World's Columbian Exposition in Chicago in 1893, a Congress of Religions was held. It was attended by representatives of the Buddhists, Mohammedans and other Asiatic religions, as well as by all Christian denominations. No effort was made at that time toward the establishment of a universal religion, but the possibility of establishing such a religion has been much commented upon since that time, and especially since the beginning of the great world conflict, which was participated in mainly by the followers of the Christian religion, each of the contestants praying to the same God for victory.

The Utopian of yesterday is the commonplace of to-day, the dream of to-day is the reality of to-morrow. We are prone to forget that our own short life-time is but as a small fraction of a second in eternity and we strive, in our imagination at least, to crowd into that small period of one generation the reforms for which the world will be ready only many generations hence.

These two subjects for standardization, that I have just discussed, would hardly seem befitting in our present highly practical age, and especially before a society which deals only with the strictly concrete subject of engineering materials. The standardization of language and religion is looked upon to-day as absolutely idealistic, but I feel very safe in predicting that in some future generation they will surely be a reality. I will now proceed with the more concrete subjects for standardization.

3. *International System of Weights and Measures.*—All are agreed that the metric system is ideal. It is in use by every civilized nation with the exception of the United States and Great Britain and some of her colonial possessions. An association, having as its object the world-wide adoption of the metric system, is in existence. This association, known as the Metric Association, is at the present time taking advantage of the world-wide desire for closer co-operation by carrying on a strong campaign for the adoption of the metric system in England and in the United States.

"Metric System" British Invention

The old German Osterling-Hanseatic League, which for hundreds of years controlled the trade of England, introduced the British pounds, both sterling and avoirdupois. We fell heir to these standards, which had been forced upon the British, through the British possession of a large part of the United States prior to the revolutionary war.

It was James Watt, the eminent scientist of Great Britain, who invented a few years after the American revolution, the decimal system of weights and measures now embodied in the metric system. Unfortunately, we did not adopt the Watt system in the early days of our independent existence, neither did England adopt it notwithstanding the fact that it was a British invention. Germany, however, soon after the war of 1870 did adopt it. Germany, during its war with France, having acquired a closer familiarity with the decimal system, was brought to a realization of its superiority over their own system. The metric system is referred to as the French system because of the French unit (the meter) employed.

To change from one system of weights and measures to another is no easy matter and it is exceedingly costly. The advantages, however, to be gained are so far reaching that the loss occasioned would be soon wiped out. We are to-day suffering because of the unfortunate choice and adoption years ago of a cumbersome system. To rid ourselves of this is analogous to taking a large dose of quinine, bitter and disagreeable, but nevertheless effective, with the patient better off for having taken it.

4. *International Standard of Temperature.*—How absurd is our Fahrenheit scale, and how confusing to have one scale for scientific expression and another for commercial usage.

Other Suggested International Standards

5. *International Coinage System.*—Why not a system of coinage, as well as a system of weights and measures, based on the principle of the divisibility by ten?

6. *International Gauging System.*—How perfectly absurd are the various systems based upon numerals having no particular significance. The only scientific manner in which to express gauge thicknesses for sheet, wire, cable, etc., is in the decimal system, using preferably the metric unit.

7. *Miscellaneous Standards.*—In addition to the above standards, other standards such as screw threads, electrical rating, power rating, etc., can be internationally adopted. Already some progress in these directions has been made by the co-operation of the British Standards Committee and the American Society of Mechanical Engineers, American Institute of Electrical Engineers, and through other co-operative work.

8. *International Standards of Material.*—So long ago as 1898, there was organized in Philadelphia the American section of the International Association for Testing Materials, which section was later incorporated as our present

society, which then became affiliated with the International Association for Testing Materials. Unfortunately, the International Association was opposed to the formation of international specifications for materials, and did not encourage the organization of strong national groups. It is questionable, if it is practicable or desirable, to revive the old International Association.

In this connection, at its quarterly meeting in April, your executive committee passed the following resolution:—

"*Resolved:* That the American Society for Testing Materials looks with favor upon the proposition of inquiring diligently whether an International Society for Engineering Materials can be formed to take up and broaden the work formerly done by the International Association for Testing Materials.

"Dr. H. M. Howe, past-president of this society, is going to Great Britain and France on a number of missions of a similar general nature, and we should be glad if the appropriate engineering bodies in those and other European countries would discuss with him, as our representative, the propriety of such a step and the means by which it might be brought about.

"We believe that provision should be made for admitting the neutral countries into this organization.

"We believe that the work of such an organization should be broader than was that of the International Association for Testing Materials, and that it should cover the development of knowledge of engineering materials and stimulate the science of testing materials, leading to the erection of international specifications as standards of reasonableness."

9. *International Standards of Testing.*—This is a matter which is of very great importance, and would logically come within the scope of the new international society, if this becomes a reality.

It is to be hoped that through the world war the old "sores" established upon the principle of careful selfishness will have been largely eliminated, and through a League of Nations there shall be established a permanent basis upon which humanity may progress upon modern lines, leaving behind it the old prejudices and really establish a brotherhood of man, which may rest upon a permanent foundation having a realization that the human race is after all but one large family, and that national border lines are but of artificial creation.

Standardization Bodies

The work of standardization in this country has been more or less fragmentary. Such work has been undertaken by individual manufacturers, also by individual consumers, and by associations representing only producers and associations representing only consumers.

A great deal of creditable work has been done by the National Bureau of Standards and some work has been undertaken by the American Institute of Mechanical Engineers, although the constitution of the latter society forbids the adoption of standards. This society, however, accepts its standard committee reports and sets its seal of approval upon the committee's recommendations.

A vast amount of work has been done by the Society of Automotive Engineers in the standardization of automobile parts and recently in aircraft parts. The Master Car Builders' Association and the Master Mechanics' Association have directed their efforts largely to standardization of railroad rolling equipment. The American Railway Engineering Association has devoted its attention primarily to railway subjects. The American Institute of Electrical Engineers and the Electric Power Club have undertaken much standardization work in connection with electrical equipment. Other standardization bodies are at work in various fields.

With the object in view of co-ordinating the standardization work of these various bodies, to foster co-operation between all interested organizations and government departments and to avoid duplication of effort, during the last year the American Engineering Standards Committee was organized. This committee was formed by joint action of five national engineering societies. Our society, being one of that number, therefore became one of the founder societies which organized this committee.

The work of this committee had only about begun when action was taken toward greatly enlarging the size and scope of the committee as originally planned, and proposals were set forth and preliminary action taken to reorganize the committee into an American Engineering Standards Association embracing the subject of safety codes, fire protection, etc.

A considerable amount of discussion has been taking place, questioning if there is any added advantage in having the seal of approval of this committee placed upon the specifications presented to it. It is this function only which the American Engineering Standards Committee contemplated exercising, and this policy will no doubt also prevail if the committee is enlarged and organized as the American Engineering Standards Association. It is quite a serious question as to which is the better method: To grow slowly and conservatively, beginning with an amount of work which can be expected to be handled properly in a reasonable length of time; or to immediately attempt to handle the vast amount which has been more lately contemplated and in so doing incur the danger of at once becoming cumbersome and top-heavy. This is a problem which will remain for the interested societies to pass their judgment upon. Personally and unofficially, I feel that there is a real need and a real field for such a committee or association, and it but remains for the various details as to organization, policy and methods to be worked out and these should have most careful consideration.

Standards Association and Specifications

I feel that the seal of approval of such a committee or association would give great weight and added recognition to a specification. I believe, however, that it would be a decided mistake for such a body to attempt to pass upon the substance of a specification, or to choose between two conflicting specifications covering the same subject which may be presented by two distinct standardizing bodies. No such specification should have the seal of approval unless the specification representing the joint action of such bodies be presented. All such standards, when finally adopted as American standards, should be ever open for revision, otherwise practice will become crystallized.

National engineering bodies are in operation in England, Canada, France and Holland, and it can be confidently predicted that such bodies will be organized in other countries in the near future. Because of our present excellent and rapid means of communication, all the countries of the world are being brought in much closer relationship than ever before and in the immediate future there will begin an era of intermingling of the peoples of the various nations of the earth to a far greater extent than ever before and it is therefore reasonable to assume that before many years have elapsed the needs of the world will demand international standardization to an ever-increasing extent.

The Union of Canadian Municipalities is holding its annual convention this week at Kingston, Ont. Mayor Bouchard, of St. Hyacinthe, Que., is president. H. G. Acres, hydraulic engineer of the Hydro-Electric Power Commission of Ontario, and A. Amos, chief of the Hydraulic Service of Quebec, are on the program for addresses on the undeveloped water-powers of Ontario and Quebec.

Chairman Smithers, of the Grand Trunk Railway, is expected in Ottawa soon to discuss with the government the question of the acquisition of the Grand Trunk by the govment as part of the national railway system. The negotiations in London last summer proved abortive. While the company needs financial assistance, and is prepared to sell out, it is essentially a question of price. The government's offer, which it has not shown a disposition to raise, but which the company has declined to accept, contemplates a 999-year lease, the assumption of liabilities and the guarantee of a rate of interest on the preferred stock equivalent to an average dividend during a term of years when the stock earned dividends. Something would probably be paid also on the common stock.—From "The Toronto Telegram."

MATHEMATICIANS ENTER INDUSTRIAL FIELD

PROBABLY for the first time in the history of science, professional mathematicians have formally entered the industrial field. Three New York mathematicians have established a consulting office with the object of handling special problems arising in industrial work for the solution of which the knowledge of mathematical specialists can be utilized to advantage.

Each of the members of the firm has been privately engaged for some time in work of this nature in addition to his other professional activities, and they state that "it was at the suggestion of clients that the decision was made to set up a consulting service which would extend to the industrial world the resources of modern, pure and applied mathematics."

"Problems come up in practically all technical fields," they write, "for the satisfactory solution of which the expert application of mathematics is essential. Directors of technical enterprises do not hesitate to call in the consulting engineer, consulting chemist, patent attorney or efficiency expert, but the mathematical features of technical problems are often left without adequate treatment. We are sure that this is due neither to a reluctance of industrial managers to consult mathematicians nor to a lack of desire on the part of mathematicians to handle industrial problems, but rather to the fact that men fitted for consulting service in this field have heretofore been too far removed from the industrial world. It is with the expectation of being of important service to the technical public, that we announce the establishment of our office."

The new firm will be known as Dantzig, Pfeiffer & Ritt, with offices at 500 West 116th Street, New York City. Dr. T. Dantzig is a graduate of the University of Paris. He has taught at Indiana and Columbia Universities, and during the war was in charge of the mathematical work of the instrument section of the U. S. Ordnance Department. Dr. G. A. Pfeiffer is a graduate of the Stevens Institute of Technology. He has taught mathematics at Harvard, Princeton and Columbia Universities, and is associate editor of the Annals of Mathematics. Dr. J. F. Ritt is a graduate of Columbia University. For three years he was in the Naval Observatory and has since taught mathematics at Columbia. During the war he was one of the chief ballisticians in the U. S. Ordnance Department.

Among the industrial applications of pure mathematics in which the firm claim that their services will be useful, are the following:—

Problems in statistics and probability; design of measuring and computing apparatus; design of optical instruments; mathematical treatment of problems in mechanism; mathematical formulation for patent claims of principles underlying inventions; scientific development of inventions; problems in aeronautics; and preparation of graphs, diagrams and charts.

WINNIPEG RIVER POWER CO., LTD.

ACTIVE work has begun on the construction of the new hydro-electric plant for the Winnipeg River Power Co., Ltd., on the Winnipeg River, 14 miles north of Lac du Bonnett, Man. The design contemplates the ultimate installation of six units of 28,000 h.p. each. The initial installation will be two units. The plant is being built by the Northern Construction Co., Ltd., for the power company, which is a subsidiary of the Winnipeg Electric Railway Co.

Before the war it became evident that the railway company would soon require a large quantity of power, but after plans had been prepared and a standard-gauge railway built from Lac du Bonnett, on the Canadian Pacific Railway, to the power site, it was found that the finances of the company did not permit a continuance of the enterprise.

After the armistice the project was revived, but the war had played havoc with the finances of the railway company and it was unable to assist further in the financing. The late A. C. Mackenzie, who was then president of the Northern Construction Co., entered into an agreement with the power company that his concern would build the dam and finance the cost of the undertaking until such time as the power company's bonds could be sold. No money will be due the construction company until the fall of 1920, by which time it is expected that the bonds will be marketed.

The main dam will be over 2,000 ft. long and 70 ft. high, and will be built of reinforced concrete; the power house will be of steel and brick, 450 ft. long by 140 ft. wide and over 100 ft. high.

The power from the new plant will be transmitted to Winnipeg over a 70-mile line with steel towers. A 65 ft. by 255 ft. steel-and-brick transformer station will be built at Winnipeg. Another line will connect the new plant with the present transmission line from Pinawa to Winnipeg at a point of about five miles south of Lac du Bonnett. The new plant will thus be connected with the city by two separate lines located at a considerable distance from each other.

F. A. Martin, who was formerly in private practice at Niagara Falls, N.Y., is in charge of the design of the plant. He has established an office in Winnipeg. R. S. & W. S. Lea, of Montreal, are the consulting hydraulic engineers, and Louis J. Hirt, of the Pearson Engineering Corporation, New York, has also been retained in an advisory capacity.

PORT COLBORNE ELEVATOR INVESTIGATION

FOLLOWING are the members of the board that has been appointed by the Dominion government to investigate the dust explosion in the government-owned grain elevator at Port Colborne, Ont., which last week killed ten workmen and badly wrecked the $2,000,000 structure:—Lieut.-Col. C. N. Monsarrat, consulting engineer to the Department of Railways and Canals; A. St. Laurent, assistant deputy

minister of the Department of Public Works; D. W. McLachlan, engineer in charge of the Port Nelson terminals of the Hudson Bay Railway; John Murphy, electrical engineer of the Department of Railways and Canals. The board is given full power to call witnesses. It is to have charge of salvaging the grain and is to make recommendations as to reconstruction.

PERSONALS

JOHN MURPHY, of Ottawa, Ont., who recently announced that he had obtained excellent moving pictures showing the formation of frazil and anchor ice, is the electrical engineer of the Department of Railways and Canals and of the Board of Railway Commissioners for Canada. Mr. Murphy was born December 17th, 1868, in Ottawa. In 1884 he graduated from the College (now University) of Ottawa, and joined the staff of the Bell Telephone Co. From 1884 he was also connected with Ahearn & Soper, who, a short time previously, had formed an electrical supply and agency house. As Mr. Ahearn was also the Ottawa manager of the Bell Telephone Co., and Mr. Soper the superintendent of the Canada Mutual Telegraph Co., Mr. Murphy came into intimate contact with the work of these two concerns. During the latter part of 1885 and the following year, Mr. Murphy was in charge of Gilmour & Co.'s arc light plant at their Gatineau mills at the falls near Chelsea, Que., incidentally acting as assistant to the general superintendent during the construction of new mills and workshops. In the spring of 1887, Ahearn & Soper formed the Chaudiere Light, Heat & Power Co., engaging Mr. Murphy to assist in the installation of the lighting system and to take subsequent charge of its operation. This company at first rented water power but soon built its own hydraulic and steam plants. Mr. Murphy was power superintendent, and practically the whole engineering staff under Mr. Ahearn, who acted as president and chief engineer. In 1894 the Chaudiere Co. and two other concerns were amalgamated as the Ottawa Electric Co., bringing five water power plants and one steam plant under its management, and Mr. Murphy was appointed Superintendent of Power Houses, retaining that title until 1906, when he was appointed to his present position with the Department of Railways and Canals and the Railway Commission. In 1891 the Ottawa Electric Railway began operation, having also been organized by Ahearn & Soper. Mr. Murphy acted as consulting engineer to this enterprise from its inception until 1906. From time to time he also acted as consulting engineer to a number of other enterprises, including, in 1902, the Montreal Locomotive Works at Longue Point, and in 1910, the Dominion Iron & Steel Co. and the Dominion Coal Co. During the last year of the war, the Fuel Controller of Canada appointed Mr. Murphy as his special agent to prevent coal consumption for the production of power at points where hydro-electric power was available. Many thousand tons of coal were saved as a result of Mr. Murphy's efforts at a time when coal was the most important of all products to a very great many Canadians. Ever since his appointment by the Federal Government, Mr. Murphy has been acting as consultant for almost every department of the government in which hydraulic or electrical problems have arisen. He is a member of the Dominion Power Board, and has been a member of the Canadian section of the International Electro-Technical Committee since its formation. He is also a fellow of the American Institute of Electrical Engineers and a councillor of the Engineering Institute of Canada. In 1915 and 1916, Mr. Murphy was chairman of the Engineering Institute's Ottawa branch. At the Institute's last annual meeting, he read a paper on railroad electrification, and also discussed, in a most interesting manner, hydro-electric ice troubles.

CAPT. J. P. CORLEY, of New York, has arrived in Canada for the purpose of taking charge of the pump department of the Canadian Ingersoll-Rand Co., Ltd. His headquarters will be at the company's Toronto office.

LT.-COL. H. R. LORDLY, formerly construction engineer, Lachine Canal, has returned to Montreal from France, and will open an office as consulting engineer. Col. Lordly took the 5th Pioneer Battalion overseas in 1916.

N. S. BRADEN, sales manager of the Canadian Westinghouse Co., Ltd., of Hamilton, has been elected vice-president of the company. H. M. BOSTWICK, assistant sales manager, has been appointed sales manager to fill the vacancy created by Mr. Braden's promotion.

GEO. K. MCDOUGALL, consulting engineer, Montreal announces that he has taken Major E. Raymond Pease, D.S.O., into partnership. The name of the new firm will be McDougall & Pease. They will specialize in industrial applications of electricity, illuminating engineering, electric power stations and high voltage power transmission.

MAJOR N. M. HALL, O.B.E., has arrived home from overseas. Major Hall graduated from McGill University in 1907, in mechanical engineering. Going to Vancouver, he became associated with the firm of Ducane, Dutcher and Co., consulting engineers. In 1915 he enlisted with the Royal Engineers as a lieutenant. He went to France in December, 1915, and won his majority on the field.

ROBT. H. PARSONS, who, previous to the war, was in charge of the water works of the city of Edmonton, is now in Canada in the interests of John Birch & Co., Ltd., London, Eng., with whom he has accepted a position as sales engineer. Mr. Parsons will make his headquarters in London. During the war he was with the Royal Engineers at first, and later, with the Ministry of Munitions.

M. U. FERGUSON, city engineer of St. Thomas, Ont., has resigned, owing to alleged interference with his department by the chairman of the Board of Works. Mr. Ferguson is planning to enter the contracting field. He has been city engineer of St. Thomas for over six years, and for several years previously was city engineer of Stratford, Ont. Before going to Stratford, he was engineer on the location and construction of a number of railway lines.

H. E. M. KENSIT, who joined the C.E.F. in September, 1915, has returned to the Dominion Water Power Branch, Ottawa. He was attached to the Canadian Engineers for two years, and after being wounded at Vimy Ridge was transferred to the Ministry of Munitions, England, for a further seventeen month. Since the armistice he has represented the Dominion Water Power Branch as a member of the water power committees now sitting in England, including that of the Conjoint Board of Scientific Societies on water powers of the Empire, and that of the Board of Trade, formed at the request of the Ministry of Reconstruction, on the water-power resources of the United Kingdom.

OBITUARY

GEO. H. BAIRD, chief draftsman of the Public Works Department, Province of Manitoba, died last month suddenly at his residence in Winnipeg.

WORLD IS ON HIGHER PRICE LEVEL

(Continued from page 220)

materials are more likely to be somewhat higher on the average in 1920, than at present, rather than lower.

Not only is the demand for houses imperative and the cost of construction cheap in proportion to prices of commodities in general, but there is every prospect that the return to those who invest in building now will adequately cover present construction costs.

Rents and Property Value

Rents and property values have, naturally, been slow in adjusting themselves to the new price level. It was reported at the beginning of the year that in 52 cities rents on the average have increased 105 per cent. In some cities they had increased 40 per cent. to 50 per cent. That was merely the beginning. Rents have advanced everywhere since January, and real estate valuations have advanced in proportion to the advances in rent.

Placing cots in churches is only a temporary measure of relief. Appointing committees to investigate rent profiteering may ameliorate the inconveniences of the adjustment to new rent levels. Perhaps some people have profited by the situation who have little claim in justice to the profits. Adjustments to new economic conditions are not always accomplished easily. The only practical solution of the problem of the shortage of housing facilities is the building of houses. The ultimate solution of the problem of high rents is the resumption of all business activities to the extent that the tenants can earn enough money to pay the rents.

There is little likelihood that the building of new houses will cause rents to decline, for the rents on the new houses will have to be adjusted so as to give an adequate return on the amount invested in the new buildings.

H. P. Eddy, of Boston, Mass., who is consulting engineer to the sewerage commission of Milwaukee, Wis., was in the latter city recently in order to test the Jones Island sewage disposal plant. He states that the experiments conducted have demonstrated the efficacy of the activated sludge system of treating sewage, as worked out under T. C. Hatton, chief engineer of the commission. Mr. Eddy was a member of the original commission which investigated the sewage question in Milwaukee ten years ago, whose report resulted in the decision to build a disposal system. Since then Mr. Eddy has been retained as consulting engineer. He is quoted by the Milwaukee newspapers as saying: "My visit here was to study the results of experiments made since April 1 in the pressing and drying of sludge to make it suitable for sale as a fertilizer base, also to examine the results of the operation of a demonstration plant since the fall of 1918. All these experiments have been made most carefully and carried out to my entire satisfaction. I am convinced that the investigations made at the Jones Island plant have been of great value in solving the problem under consideration. The results of the experiments and the operation of a portion of the plant demonstrated, in my opinion, the entire practicability of the process, that sewage disposal by the activated sludge process is practical, and that an effluent of the standard adopted by the sewerage commission can be produced. While there are some details of design which remain to be worked out, the results of the demonstration conducted during the past year indicate that the general plan proposed by T. C. Hatton in August, 1917, is the plan for the treatment of sewage by the activated sludge method which is best adapted to local conditions. The activated sludge process of sewage treatment as developed by the experiments at Jones Island will purify sewage as well or better than any other method of sewage treatment at present known or in use. Sewage treated by this process will be in a satisfactory condition for discharge into the lake. The solids produced from the activated sludge process as suggested for the Milwaukee plant, can be reduced to a fertilizer base from the sale of which the city will receive substantial returns."

HOW TO REDUCE RISKS IN EARTHWORK

(Continued from page 224)

gang. This is often not so easy of accomplishment as it sounds. Usually, the only practical way of estimating the daily yardage is by counting the loads; but loads may vary considerably in size, and it may not be easy to keep tabs on the number of loads.

Carloads and wagonloads vary because of differences in the kind of earth, differences in the resistance to traction, difference in attention given to the loading, etc. Study every cause of variation in size of loads with a view to learning how to estimate the "place measure" size of a load under given conditions.

Estimate Yardage Accurately

Your own estimates of yardage, based on the count of loads, should be compared with monthly cross-section estimates made by engineers. Do not think the engineer is necessarily wrong because his monthly estimate is far below your estimate. Perhaps your "tally" is wrong. More probably you have estimated too liberally as to the size of the average load. Buy two mechanical counters or "tally machines" for use at the pit and dump.

My brother, W. A. Gillete, has devised a satisfactory method of estimating the daily yardage handled by drags, fresnos and wheelers. A timekeeper on horseback rides from gang to gang, spending about 20 min. at each gang, during which time he counts the number of scraper loads moved by the gang. Three or more such counts are made every day for each gang, and upon these counts is based an estimate of the yardage excavated each day by every gang. The accuracy of this intermittent timing method of estimating yardage is astonishing. The engineers' monthly estimate seldom differs more than 5% from the estimate thus made by the timekeeper. The great merit of such daily estimates of yardage consists in showing at once the relative efficiency of different methods, machines and men.

Compare Labor With Machines

I have mentioned the unreliability of most common laborers on grading work. This unreliability, coupled with the high wages now paid to common laborers, is leading to a greater use of machinery than ever before, even on small jobs. In China, with wages at 15 cents a day, machinery could seldom compete with hand work, for the interest, repairs and depreciation on the plant alone exceeded the cost of doing the work by hand in most cases. That is one extreme. At the other extreme we now have American unskilled labor getting 30 to 60 cents an hour, the average being about 40 cents. Skilled labor has risen about 60% in price as compared with a rise of about 100% for unskilled labor. Machinery has not risen in price as much as skilled labor, and excavating machinery grows better every year. Hence it is that nearly all of us must revise our pre-war ideas about the use of machinery.

High wages lead inevitably to a greater use of machinery. This has long been evident on the Pacific Coast, where contractors found it profitable, long before the war, to use more machinery than was customary in the Central, Southern and Eastern States. Wages on the Pacific Coast averaged about $2.50 a day for common labor prior to the war, whereas about $1.75 was the average in the East. That difference alone justified the greater use of machinery in the far West. Is it not clear, then, that with common labor wages double what they were five years ago, there must be a greatly increased use of machinery in construction work?

Hereafter the slogan of the far-sighted contractor will be: More power and less muscle; fewer men and greater hustle.

J. A. Ellis, Director of Municipal Affairs of Ontario, estimates that 1,500 houses will be built this year under the provisions of the Ontario Housing Act. A far greater number will be built next year, he states.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

ADDITIONAL TENDERS PENDING

Further information may be had from the issues of *The Canadian Engineer*, to which reference is made.

BRIDGES, ROADS AND STREETS

Amherst, N.S.—Tenders will be received until 12 o'clock noon, August 15th, by the department of public works, Ottawa, for grading, construction of pavement, sidewalks, etc., for waterproofing basement walls and for mastic floor, drill hall, Amherst, N.S. Plans, etc., at office of chief architect, Ottawa; caretaker, public building, Amherst, N.S.; superintendent public buildings, St. John, N.B.; inspector Dominion buildings, Halifax, N.S. R. C. Desrochers, secretary.

Belleville, Ont.—Tenders will be received until 5 p.m., August 15th, by the city council, for construction of approximately 25,000 sq. yds. asphaltic concrete pavement, curb, gutter and storm sewers. J. G. Mill, city engineer.

Halifax, N.S.—Contract has been awarded by the Relief Commission for construction of over a mile of streets, 80 ft. in width, to the Bedford Construction Co. Contract price, approximately $30,000.

Quebec, Que.—Plans are being prepared by the department of public works for a new batiscan bridge for the Quebec-Montreal highway. Tenders will probably be called on completion of plans.

Regina, Sask.—Contract has been awarded by the city council, for construction of street pavement and spur track pavement, to the Crown Paving and Construction Co., Calgary, Edmonton and Regina. D. A. R. McCannel, city engineer.

Regina, Sask.—Tenders will be received until noon, August 18th, by the department of public works, Ottawa, for construction of pavement in lane adjoining post office building. Plans, etc., at offices of chief architect, Ottawa; clerk of works, Regina; resident architect, 802 Lindsay Building, Winnipeg, Man. R. C. Desrochers, secretary.

Saskatoon, Sask.—Contract recently awarded by city council for paving Saskatchewan Crescent to Bitulithic Co., Winnipeg. Contract price, $27,000.

Ste. Martine Municipality, Chateauguay, Que.—Tenders will be received until 7 p.m., August 30th, by the municipal council for construction of about 5 mls. of bituminous macadam road, including bridges. Nap. Mallette, secretary-treasurer.

Three Rivers, Que.—Contract has been awarded by the department of public works, for sidewalks and grading for public building, to A. Héon & Co., Three Rivers. Contract price, $13,808. R. C. Desrochers, secretary.

Toronto, Ont.—The city council has decided to widen Bloor St. west of Quebec Ave., to 86 feet. R. C Harris, commissioner of works.

Vancouver, B.C.—A deputation from the Vancouver Automobile Club will request the provincial government to extend the road construction program, which was announced to be about three miles in length between New Westminster and the international boundary, to include the entire distance. R. H. Gale, mayor.

Webbwood, Ont.—Tenders will be received until August 23rd by the town council for construction of 1,000 lin. ft. of 6-ft. concrete walks. J. C. McMillan, clerk.

Windsor, Ont.—The ratepayers have voted against the proposed by-law for construction of sidewalks aggregating 28.27 mls. in length and to cost $100,000.

York Township, Ont.—Contracts have been awarded, by the township council, for construction of sidewalks as follows: on Hillbrow Ave., to Walton & Rowell, $1,720.00. Rejected tenders from A. Johnson, $3,250.00; Frank Angotti, $3,225.00; W. Hughes, $2,902.00; National Construction Co., $3,498.00. Westwood Ave., to Walton & Rowell, $1,297.00. Rejected tenders from A. Johnson, $2,520.00; Frank Angotti, $2,700.00; W. Hughes, $2,150.00; National Construction Co., $2,388.00. Frank Barber, engineer.

York Township, Ont.—The township council proposes to construct the following pavements: 24 ft. Tarvia X on Glenholme Ave., Medway Ave. to Rogers Rd.; cost, $2,000. Westmount Ave., from north end of pavement to Miller Ave.; cost, $3,300. Concrete sidewalks on Bernice Cres., N. side, 4 ft. 6 in., with curb; cost, $4,600. Dennis Ave., N. side, 5 ft. 6 in., with curb, from Weston Rd. to Syndicate Ave.; cost, $1,800. Gamble Ave., S. side, 4 ft. 6 in., from Don Mills Rd., to Leslie St.; cost, $4,700. McRoberts Ave., both sides, 4 ft. 6 in., with curb, from north city limits to Summit Ave.; cost, $8,500. Poulton Ave., N. side, 4 ft. 6 in., with curb, Woodbine Ave., westerly 1,940 ft.; cost, $4,500. Torrens Ave., N. side, 4 ft., with curb, from Don Mills Rd. to Pape Ave., and a 4 ft. without curb, N. side, from Pape Ave. to Leslie St.; cost, $5,500.

WATER, SEWAGE AND REFUSE

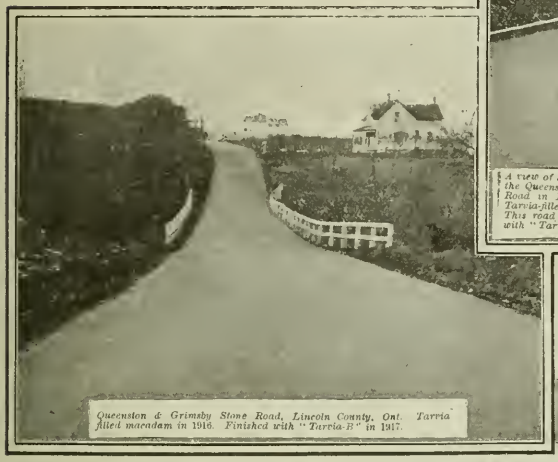
Birchcliffe, Ont.—A public meeting will be held on September 15th to discuss plans drawn for a new waterworks system for part of Scarboro' township. E. A. James, engineer. Estimated cost, $100,000.

Dalhousie, N.B.—Tenders will be received by the town council until 8 p.m., August 15th, for excavation and grad-

Tarvia

Preserves Roads
Prevents Dust~

A view of Jordan Hill section of the Queenston & Grimsby Stone Road in Lincoln County, Ont. Tarvia-filled macadam in 1916. This road was treated in 1917 with "Tarvia-B."



Queenston & Grimsby Stone Road, Lincoln County, Ont. Tarvia filled macadam in 1916. Finished with "Tarvia-B" in 1917.

Auto-Tank Sprayer distributing Tarvia

County of Lincoln (Ont.) adopts Tarvia for all main highways—

The following letter from Mr. Lewis H. Collard tells the story of the experience of the County of Lincoln, Ont., with Tarvia roads. It proves again that Tarvia solves the good road problem satisfactorily and economically, and that Tarvia highways will stand up under the heaviest kind of traffic.

Mr. Collard writes :

"I feel that if I did not give you an unsolicited testimonial of my experience with your Tarvia products, I would not be doing my duty to my fellow municipal officers in the Dominion of Canada, who may have under their consideration the building of some more permanent highways than the old water-bound macadam type.

The County of Lincoln two years ago built about two miles of Tarvia road on its main highway from the village of Jordan, running west, better known as the Queenston & Grimsby stone road, a road which carries the traffic from Canada to the Niagra Frontier and from the United States to Hamilton, Toronto, and farther east, and therefore is one of the heaviest travelled roads in the Province of Ontario, both in tourist and local traffic, having as high as one thousand automobiles and trucks passing over it in a day, and I can only say, after two years of this kind of traffic, the road is in first class condition to-day, and has pleased the County of Lincoln so much that they intend to build their main highways in the County Road system of the same type."

(Signed) LEWIS H. COLLARD,
Chairman, Lincoln County Roads

Nothing more need be said, except to remind you again that no matter what your road problem may be—whether you require a road binder, a dust preventive, a road preserver, or a patching material—there is a grade of Tarvia for the purpose.

The Barrett Company
LIMITED

MONTREAL TORONTO WINNIPEG ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S. VANCOUVER

ing of all earth and rock, supply of material and construction of water-works reservoir. F. W. Holt, engineer, 55 Canterbury St., St. John, N.B. J .E. Stewart, town clerk, Dalhousie.

North Bay, Ont.—Contract has been awarded by the town council for construction of sewers on Cassels, McIntyre, Bloem and Worthington Sts. to Angelo Chinco, North Bay, Ont. H. J. McAuslan, town engineer.

Winnipeg, Man.—Contract has been awarded by the city council, for construction of water mains on Centennial, Lindsay, Sandhurst and Sylvia St., to Dominion Construction Co., 676 Main St., Winnipeg. C. J. Brown, city clerk.

Woodstock, Ont.—The provincial board of health, Ontario, has notified the city council that they will not approve of the plans submitted to them of the new sewerage system until the complete details, showing method of disposal of the sewage is included. It is probable that the activated sludge process will be installed. Additional cost, $10,000.

York Township, Ont.—Contracts have been awarded by the township council for construction of water mains as follows; to Murphy Construction Co., Bernice St., $3,830.70, Florence St., $2,301.50, Thornhill St., $3,882.45; to McNamara Bros. & Co., Sault Ste. Marie, Hanson St., $2,220.35, Atlas St. N., $958.95, Robina St., $3,713.60, Tay St., $2,665.35; to Angelo Cavoti, Miller St., $1,587.75. Rejected tenders from Murphy Construction Co., Hanson St., $4,878.50, Miller St., $2,009.50, Atlas St. N., $2,074.50, Robina St., $6,370.00, Tay St., $5,275.00; McNamara Bros. & Co., Bernice St., $5,823.80, Miller St., $1,603.60, Florence St., $3,436.70, Thornhill St., $5,710.20; J. H. McNight Construction Co., Bernice St., $4,806.50, Atlas St., N., $1,264.55, Tay St., $3,837.00, Florence St., $2,764.50, Thornhill St., $5,532.50; Angelo Cavoti, Bernice St., $4,455.10, Hanson St., $2,473.00, Florence St., $2,536.50, Thornhill St., $4,444.40. Frank Barber, engineer.

York Township, Ont.—The township council proposes construction of 6-in. cast-iron water mains and appurtenances on the following streets: Waterworks Section A—Amherst Ave., from Oakwood Ave. westerly to Lauder Ave., 1,172 ft.; Jesmond Ave., from Oakwood Ave. westerly to Glenholme, 810 ft.; Ashbury Ave., from Oakwood Ave. to west end, 680 ft.; Roach Ave., from High St. northerly to Vaughan Rd., 1,236 ft.; Humewood Ave., from High St. northerly to Vaughan Rd., 1,316 ft. Estimated cost, $20,000. Craydon Ave., from Weston Rd. to railway tracks, 900 ft.; Ray Ave., from Weston Rd. to railway tracks, 450 ft:; Rutherford Ave., from Weston Rd. to railway tracks, 875 ft.; Victoria Blvd., from Weston Rd. to railway tracks, 760 ft.; Eglinton Ave., from Weston Rd. to railway tracks, 533 ft.; Brownhill Ave., from Eglinton Ave. to south end, 926 ft.; Barr Ave., from Brownhill Ave. to Weston Rd., 216 ft.; Elora Ave., from Bartonville Ave. to Jane St., 406 ft. Estimated cost, $20,000. Cliff St., Bushey Ave. and Jasper Ave., from Lambton Ave. to Langdon Ave., 1,485 ft.; Jasper Ave., from Cliff St. to west end, 124 ft.; Langdon Ave., from east end to west end, 316 ft.; Orla Ave., from Lambton Ave. southerly 550 ft.; Chryessa Ave., from Lambton Ave. southerly 1,134 ft.; Gray Ave., from Lambton Ave. southerly 758 ft.; Outlook Ave., from Beechwood Ave. to Chryessa, 192 ft.; Humber Crest Blvd., from Weston Rd. to west end, 1,580 ft. Estimated cost, $14,000. Lauder Ave., from Rogers Rd. to Vaughan Rd., 3,200 ft. Estimated cost, $12,800. Mitchell Ave., from Eglinton Ave. to Jackes Ave., 1,136 ft. Estimated cost, $4,500. Northland Ave., from Weston Rd. to Spears St., 1,974 ft.; Lapp St., from Northland Ave. to McCormack St., 814 ft.; Spears St., from Northland Ave. to north end, 344 ft.; McCormack St., from city limits to 671 ft. west, 671 ft. Estimated cost, $15,000. Northcliffe Blvd., from Vaughan Rd. north to Eglinton Ave., 493 ft. Estimated cost, $1,970. Waterworks Section B—Morningside Ave., from Kennedy St. to Windermere Ave., 1,500 ft.; Lavinia Ave., from Morningside Ave. to Park Rd., 1,093 ft.; Runnymede Rd., south from Park Rd. to Morningside Ave., 1,046 ft.; Lavinia Ave., south from Morningside Ave. to the south limit of lot 18, plan M82, 259 ft.; Ostend Ave., west from Windermere Ave. to Willard Ave., 315 ft. Estimated cost, $16,650. W. A. Clarke, clerk.

LIGHT, HEAT AND POWER

Calgary, Alta.—The Hudson's Bay Co. have signed contract to purchase electrical power from the city. In agreement, is a provision by which the company agrees to operate its own plant during peak load shortage in the months of December and January, if requested so to do by the city.

Kapuskasing, Ont.—The Spruce Falls Pulp & Paper Co. will shortly commence construction of their new plant. It is said that the power will be obtained from rapids, ten miles up the river. S. A. Munday, Bradford, Pa., president.

Minnedosa, Man.—The town council has requested permission from the Public Utilities Commission, to acquire the plant of the Minnedosa Power Co., should the company fail to fulfil its obligation to supply the town with the necessary amount of light and power.

Niagara Falls, Ont.—The city council has made an agreement with the Hydro-Electric Power Commission for supply of power to Chippewa, Ont.

RAILWAYS

Brantford, Ont.—The Lake Erie and Northern Ry. have made surveys and will construct a switch line into the Holmdale district.

Fredericton, N.B.—The International Railway has been purchased by the Dominion government, and will probably be run as part of the C.N. Ry. system. H. A. Carr, K.C., Campbellton, N.B.

Galt, Ont.—The Grand River Ry. will remove their tracks from Water St. and enter the city over a private right-of-way, upon the expiration of their franchise in February, 1921. J. McCartney, city clerk.

Guelph, Ont.—The ratepayers have voted against the proposed Grand River Valley Railway agreement by which the municipal street railway was to be operated by the Valley railroad and connections established with Hespeler, Galt, Hamilton and other cities. The Hydro-Electric Power Commission opposed the by-law, Sir Adam Beck stating that the "hydro radials" would cover this field, and that the proposed agreement would interfere with the Commission's plans.

Kitchener, Ont.—The city council are contemplating purchase of the Waterloo and Wellington Railway. Estimated sale price to the city, $75,000 V. S. McIntyre, superintendent of the street railway commission, is investigating the financial side of the company.

Long Branch, Ont.—A deputation of ratepayers contemplate requesting Sir Adam Beck to take over the York radial lake shore division and operate it as a public utility.

Port Alberni, B.C.—Tenders may soon be called by the E. & N. Railway for construction of 12 miles of railway on Vancouver Island, extending the line from Port Alberni into the Great Central Lake district. R. Marpole, general executive, C.P. Ry., and president of the E. & N. Ry.

Sherbrook, Que.—The Sherbrooke Railway and Power Co. contemplates extensions to the street railway system.

Toronto, Ont.—The city council has decided to double-track west Bloor St., from Quebec Ave. to Runnymede Rd. Estimated cost, $160,000. R. C. Harris, commissioner of works.

FACTORIES AND LARGE BUILDINGS

Alderson, Alta.—Tenders will be received until noon, August 21st, by the board of trustees, Daisy Dell school district, No. 2685, for construction of a frame school building. F. Goehring, secretary-treasurer.

Bassano, Alta.—Tenders will be received until noon, August 16th, by the department of railways and telephones, Edmonton, Alta., for construction of a telephone exchange building. N. L. Harvey, deputy minister.

Brantford, Ont.—The Brantford Piano Case Co. contemplate further extensions to their plant.

Calgary, Alta.—The Bruner block on First St. West will be reconstructed as a high-class hotel. Estimated cost, $50,000. R. S. Noble, Calgary.

Castor, Alta.—Tenders will be received until noon, August 16th, by the department of railways and telephones, Edmonton, Alta., for construction of a telephone exchange building. N. L. Harvey, deputy minister.

Charlottetown, P.E.I.—Contract has been awarded, to H. and S. Lowe, for construction of an addition to St. Paul's Church. J. E. Harris, architect.

Chatham, Ont.—A new three-story brick factory building will be erected immediately by the Gray-Dort Motor Sales Co. Daniels & Vickery, Chatham.

Claresholm, Alta.—Tenders will be received until noon, August 16th, by the department of railways and telephones, Edmonton, Alta., for construction of telephone exchange building. N. L. Harvey, deputy minister.

Didsbury, Alta.—Tenders will be received until noon, August 16th, by the department of railways and telephones, Edmonton, Alta., for construction of a telephone exchange building. N. L. Harvey, deputy minister.

Edmonton, Alta.—Tenders will soon be called, by the city council and the board of the Royal Alexandra Hospital, for construction of a new wing to the main building. Estimated cost, $225,000.

Edmundston, N.B.—Tenders will be received until 12 o'clock noon, August 16th, by the chief engineer, C.N. Ry., Moncton, N.B., for construction of a car shop. C. B. Brown, chief engineer. F. P. Brady, general manager, Moncton, N.B.

Fort William, Ont.—The Kakabeka Falls Brewing Co. are extending their present buildings to accommodate an additional bottling plant.

Halifax, N.S.—Tenders will be received until noon, August 23rd, by the C.N. Ry., for construction of Transit sheds Nos. 21 and 22. Plans, etc., at the offices of resident engineer, C.N. Ry., Tunnel Sta., Montreal; chief engineer, Moncton, N.B., and the superintending engineer, 137 Barrington St., Halifax, N.S. C. B. Brown, chief engineer, Moncton, N.B.

Ingersoll, Ont.—The board of education has requested the city council to prepare a by-law for construction of a new central school. Estimated cost, $120,000. Mayor Buchanan.

Kitchener, Ont.—Contract has been awarded, by A. & C. Boehmer Box Co., for erection of addition to factory to Steve Becker. Contract price, approximately $10,000. W. C. Cowan, architect.

Kitchener, Ont.—Plans have been submitted for extension to the House of Refuge. Charles Knechtel, architect. D. Cross, mayor. Estimated cost, $88,000.

Lougheed, Alta.—Tenders will be received until noon, August 16th, by the department of railways and telephones, Edmonton, Alta., for construction of telephone exchange building. N. L. Harvey, deputy minister.

Montreal, Que.—The Montreal Amusement Co. will shortly begin construction of a new arena and skating rink building in Montreal to be completed before December 25th.

Oshawa, Ont.—Tenders will be received until noon, August 22nd, by the department of public works, Ottawa, for construction of an examining warehouse. Plans, etc., at offices of chief architect, Ottawa; superintendent of Dominion buildings, postal station "F," Toronto, and caretaker, public building, Oshawa. R. C. Desrochers, secretary.

Parkside, Sask.—Tenders will be received until 5 p.m., August 22nd, by the board of school district, No. 1445, for erection of a brick school building. W. E. Kimber, secretary-treasurer.

Port Arthur, Ont.—Tenders will be received until August 16th by the department of public works, Ontario, for construction of a dwelling-house at Port Arthur Fish Hatchery. Plans at the office of H. A. McKibbon, Whalen building, Port Arthur, Ont. H. F. McNaughten, secretary, Toronto.

Regina, Sask—Contracts have been awarded by the provincial government, for construction of the government office building on Cornwall St., to the Poole Construction Co., contract price, $149,962. Rejected tenders, Parsons Construction Co., $179,600; Minkley & Jones, $175,000; Smith Bros. & Wilson, $167,000; McKay Construction Co., $164,800; Wilson & Wilson, $158,800; Carter, Halls, Aldinger Co., $150,229. Plumbing and heating contract awarded to Regina Plumbing & Heating Co., $14,532. Rejected tenders, Yost Bros., $15,725; Whiteford Bros., $14,790.

Saskatoon, Alta.—The Interprovincial Flour Mills will erect an addition to warehouse. Estimated cost, $10,000.

Sydney, N.S.—Tenders will be received until August 25th for construction of a church at Dominion No. 4, Cape Breton. Plans, etc., may be seen at Glebe House. J. J. Macneil, P.P.

Sydney, N.S.—Tenders will be received until 12 o'clock noon, August 16th, by the chief engineer, C.N. Ry., Moncton, N.B., for construction of stores building. C. B. Brown, chief engineer. F. P. Brady, general manager, Moncton, N.B.

Toronto, Ont.—Tenders will be received until 4 p.m., August 27th, by the board of education, 155 College St., for addition to Keele St. school. Architects, Chapman & Oxley, Harbor Commission Building, Toronto. W. C. Wilkinson, secretary-treasurer.

Toronto, Ont.—Tenders will be received until 4 p.m., August 27th, by the board of education, 155 College St., for addition to Earl Grey school on Jones Ave. W. C. Wilkinson, secretary-treasurer.

Toronto, Ont.—Tenders will be received until 4 p.m., August 27th, by the board of education, 155 College St., for addition to the Duke of Connaught School, Morley Ave. W. C. Wilkinson, secretary-treasurer.

Toronto, Ont.—Tenders will be received until 4 p.m., August 18th, by the board of education, 155 College St., for local telphones and electric wiring at various schools, plumbing at Park, Dufferin and Winchester schools, concrete work at Queen Alexandra, masonry work at Brock Ave., electric motors at Roden and Ryerson, and local ventilation at York St school. W. C. Wilkinson, secretary-treasurer.

Toronto, Ont.—The King Edward Hotel Co. contemplate construction of a 15-story addition to the present hotel on King St. East. The new annex will contain 500 rooms, banquet hall to seat 1,000, convention hall to seat 2,000, and a roof garden. Construction will probably start in November and be completed within 12 months. Approximate cost, $2,000,000. G. H. O'Neil, manager.

Toronto, Ont.—The William Davies Co. will soon commence construction of their new building, 31 Queen St. West.

Viking, Alta.—Tenders will be received until noon, August 16th, by the department of railways and telephones, Edmonton, Alta., for construction of telephone exchange building. N. L. Harvey, deputy minister.

Wainwright, Alta.—Tenders will be received until noon, August 16th, by the department of railways and telephones, Edmonton, Alta., for construction of telephone exchange building. N. L. Harvey, deputy minister.

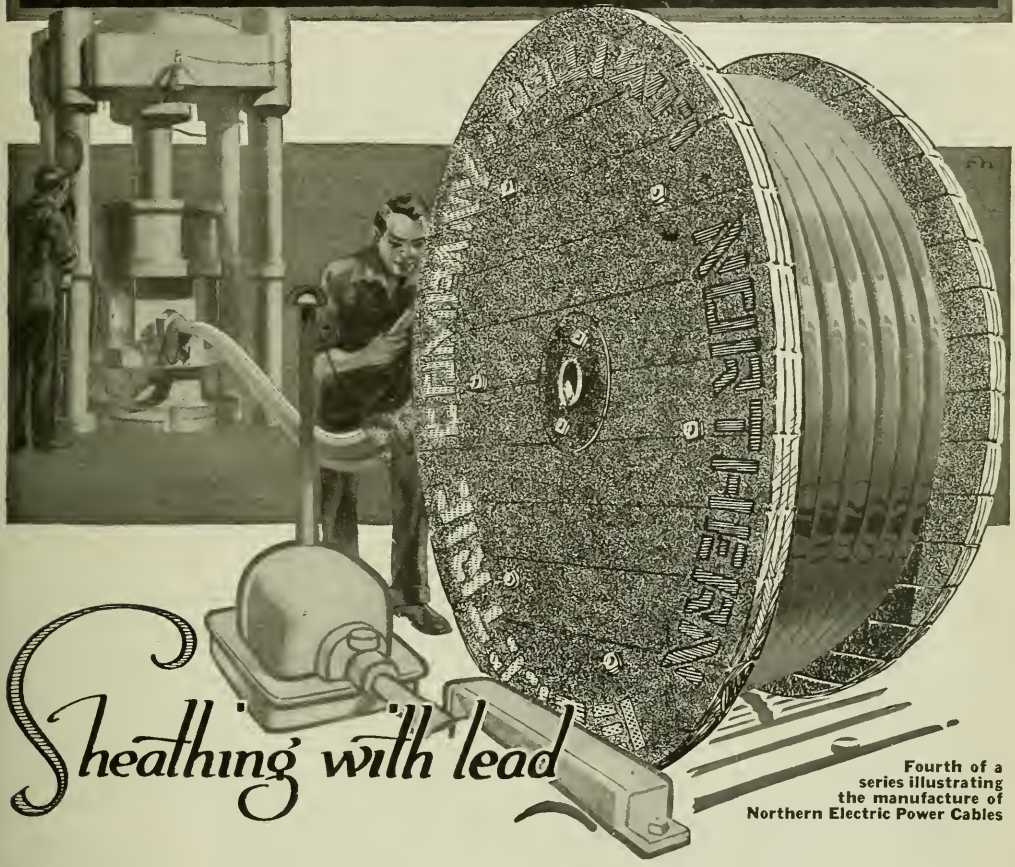
Westfield, N.B.—The town council will probably request the C.P. Ry. and the C.N. Ry. to establish a modern station building on completion of the new valley road.

Westmount, Que.—The Montreal Arena Co. have given a contract for construction of a two-story garage, to be erected on the site of the Arena, destroyed by fire two years ago.

Winnipeg, Man.—Contract has been awarded by the city council, for reconstruction of market building into civic offices, to Fraser & McDonald Construction Co. Contract price, $57,592. Rejected tenders, No. 2, $61,546; No. 3, $62,800; No. 4, $64,132; No. 5, $65,500, No. 6, $65,706; No. 7, $70,500, No. 8, $76,593. M. Peterson, secretary.

Winnipeg, Man.—Contract has been awarded by the city council for erection of a show-room building for the city light and power department to Thos. Kelly & Sons, Ltd., Winnipeg. Contract price, $41,285. C. J. Brown, city clerk.

Northern Electric



Sheathing with lead

Fourth of a series illustrating the manufacture of Northern Electric Power Cables

The Impregnated paper-insulated cable passes from a warm room through a cartridge shaped core and circular die enclosed in the lead press to the cable reel. Great pressure from a hydraulic ram forms the sheath about the cable by forcing pure lead in a semi-molten condition between the core and the die, which are arranged with the proper clearance to give the thickness of lead required. This operation requires very skilful attention. Our long experience in the manufacture of all classes of lead-covered cables ensures for our product, cable sheaths of the highest quality.

MISCELLANEOUS

Belleville, Ont.—Contract has been awarded by the Canadian Industrial Alcohol Co., Ltd., for construction of a 30,000 bushel reinforced concrete grain elevator and work house. Contractor, J. B. Nicholson, Ltd., Hamilton, Ont.

Cardston, Alta.—Contract has been awarded, for construction of a soldiers' memorial, to the Lethbridge Monumental Works.

Comox, B.C.—Contract has been awarded by the department of public works, for repairs to wharf, to the Fraser River Pile Driving Co., Ltd., New Westminster, B.C. Contract-unit prices, approximately $17,358.04. R. C. Desrochers, secretary.

Creston, B.C.—The board of trade is requesting the provincial government to immediately complete the survey of the Arrow Creek irrigation ditch and proceed with construction.

Donacona, Que.—The Donacona Paper Co. contemplate extensions to their present plant.

Fort Churchill, Ont.—The government contemplates construction of automatic lighthouses for Hudson Bay and Straits. By this device, horns, sirens and lights are controlled from shore by means of heavy submarine cables Approximate cost of lighthouse, $50,000.

Fredericton, N.B.—Contract has been awarded by the Nashwaak Pulp and Paper Co., for construction of a concrete dam on the Nashwaak River at Marysville, N.B., to the Amberson Hydraulic Construction Co., Ltd., Montreal. Contract price, approximately $50,000. N. M. Jones, general manager.

Halifax, N.S.—The Nova Scotia Steel and Coal Co. has purchased the coal-handling plant on C.N. Ry. terminals at Halifax. D. H. MacDougall, president.

Ingersoll, Ont.—The city council has decided to construct a swimming pool in the northwest corner of the new park on King St. Mayor Buchanan.

Lethbridge, Alta.—The city council contemplate installation of water meters. Approximate cost, $30,000. W. D. L. Hardie, mayor.

New Westminster, B.C.—A cordage company, operated by returned soldiers, will erect buildings valued at $80,000 and install equipment valued at $90,000 upon a site granted by the city council. Mayor Gray.

Odessa, Ont.—Contract has been awarded by the department of public highways, Ontario, for construction of concrete abutments, roadway and sidewalk floors for bridge, to Gibson & McGinnis, Portsmouth, Ont. George Hogarth, chief engineer.

Ottawa, Ont.—Tenders will be received until noon, August 18th, by the C.N. Ry., for construction of concrete culvert, abutments and piers between mileage 59, L'Orignal and Ottawa, on the Grenville subdivision. Plans, etc., at the offices of the division engineers, G.N.W. Telegraph Building, Ottawa, and Tunnel Terminal Station, Montreal. A. F. Stewart, chief engineer, 27 Wellington St. E., Toronto.

Peel Township, Ont.—Tenders will be received until 2 p.m., August 18th, by township council, for construction of municipal drains No. 1 and 2. Quantities to be excavated, 17,804.11 and 6,965 cu. yds. Edward Gainer, township clerk, Arthur, Ont.

Peterborough, Ont.—The city council will consider purchase of an asphalt paving plant. Alderman McIntyre.

Pointe Pizeau, Que.—Tenders will be received until noon, August 28th, by the department of public works, Ottawa, for repairs to wharf at Pointe Pizeau, Que. Plans, etc., at offices of district engineers, post-office building, Quebec; Shaughnessy building, Montreal, and post-office, Sillery, Que. R. C. Desrochers, secretary.

Port Arthur, Ont.—The Sucker Creek Timber Slide Co., Ltd., has been incorporated, $50,000, to construct and maintain slides, booms, piers and other works necessary to the transmission of timber down Sucker Creek in unsurveyed territory. E. J. H. Weldon, provisional director.

Port Hope, Ont.—The contract, previously reported in this column, awarded by the department of public works, Ottawa, to R. Brewder, Cobourg, for repairs to pier at Port Hope, Ont., amounted to $11,565.46, (unit prices). R. C. Desrochers, secretary.

Qu'Appelle, Sask.—Tenders will be received until August 19th, by the Starrs Point Rural Telephone Co., for extensions to system. T. Bray, Box 114, Qu'Appelle.

River Glade, N.B.—Tenders will be received until noon, August 18th, by the board of commissioners, Jordan Memorial Sanatorium, for construction of a fishway at the sanatorium dam. D. A. Carmichael, secretary.

Sarnia, Ont.—The city council contemplates construction of a concrete swimming pool for children. Alderman R. Kirby.

Saskatoon, Sask.—Tenders, separate or bulk, will be received until noon, August 19th, by the board of the Saskatoon school district No. 13, for construction of a school building, exclusive of plumbing, heating and ventilation. Wm. P. Bate, secretary, P.O. Box 1406, Saskatoon. R. Blackwood, architect, building commissioner.

Souris, P.E.I.—Contract has been awarded by the department of public works, for delivery and placing of stone on breakwater, to Phillips & Mutch, Charlottetown, P.E.I. Contract-unit prices, approximately $17,358.04. R. C. Desrochers, secretary.

Stratford, Ont.—The city council contemplate erection of a monument, in Battery Park, as a soldiers' memorial. Plans and a model of the proposed monument were presented by the committee of the Chamber of Commerce. Mayor Stevenson.

St. Thomas, Ont.—The board of water commissioners have decided to construct a large dam on Kettle Creek. The reservoir, so formed, will contain sufficient water to supply the total needs of the city.

Sydney, N.S.—The Sydney Foundry and Machine Co. has applied to the city council for a site near Anderson's Point, on the eastern side of Sydney harbor, Sydney, N.S., for construction of a drydock.

Thessalon, Ont.—Contract has been awarded by the department of public works, for reconstruction of wharf, to A. G. Tweedie, Sault Ste. Marie, Ont. Contract-unit prices, approximately $9,428.75. R. C. Desrochers, secretary.

Toronto, Ont.—No contract was awarded by the highway department, Ontario, for construction of concrete structures on provincial highway between Queenston and Jordon, in the townships of Niagara, Grantham and Louth. One tender was received but was considered excessive and was rejected. W. A. McLean, deputy minister.

Toronto, Ont.—Tenders will be received until noon, August 25th, by the C.N. Ry., for 200,000 railway ties, to be delivered on the Halifax and Southwestern branch. E. Langham, general purchasing agent, Toronto.

Toronto, Ont.—The ratepayers in the districts of Earlscourt, Oakwood, Fairbanks, Harvey and Silverthorne will request the city council to establish a modern firehall to protect those districts.

Toronto, Ont.—Contract has been awarded by the Conger Lehigh Coal Co., Ltd., for construction of a 2,000-ton circular reinforced concrete coal elevator to replace old wooden trestle at Gladstone Ave. and Queen St. Contractor, J. B. Nicholson, Ltd., Hamilton, Ont.

Toronto, Ont.—Contract has been awarded by the department of public works, Ottawa, for reconstruction of a portion of the superstructure of the east pier at the eastern entrance to Toronto harbor, to the C. S. Boone Dredging & Construction Co., Ltd., Toronto. Contract, unit prices approximately $31,095.70. R. C. Desrochers, secretary.

Victoria, B.C.—Tenders will soon be called for the first unit of the Sumas reclamation project. Estimated cost of entire project, $1,500,000.

Windsor, Ont.—The Detroit and Windsor Ferry Co. contemplate construction of a 450-ft. dock, equipped with customs and immigration offices.

The Canadian Engineer

A Weekly Paper for Civil Engineers and Contractors

Hydro-Electric Development on the Seguin River

Municipally-Owned Plant Now Being Constructed for the Town of Parry Sound, Ont., To Generate From 2,200 to 2,900 H.P.—Gravity Type Concrete Power Dam—Concrete Storage Dam at Mill Lake—Initial Expenditure, Approximately $150,000

TWO new concrete dams on the Seguin river, and a new power house with an ultimate capacity of from 2,200 to 2,900 electrical horse-power are being built for the town of Parry Sound, Ont., as a municipally owned public utility.

Parry Sound, located on the east shore of Georgian Bay, has the advantages of water transportation and service by three railways: Grand Trunk, Canadian Pacific and Canadian National. It is a county seat and the centre of an enterprising community. The population according to the last census (1911) was 3,429, but has since increased considerably, and during the war reached nearly 7,500, largely due to the great industrial activity in the neighboring town of Nobel, where plants of Canadian Explosives, Ltd., and British Cordite Co. were located. Since the armistice, business in Parry Sound has been reduced in volume and the town's officials decided that steps must be taken to ensure an adequate supply of power, so that new industries can be attracted to the town and its prosperity maintained.

The firm of C. H. and P. H. Mitchell, consulting engineers, Toronto, was asked to report upon the cost of an increased power supply, and a by-law was submitted to the citizens, who decided by a very large majority to adopt the scheme suggested by the engineers and to begin construction immediately.

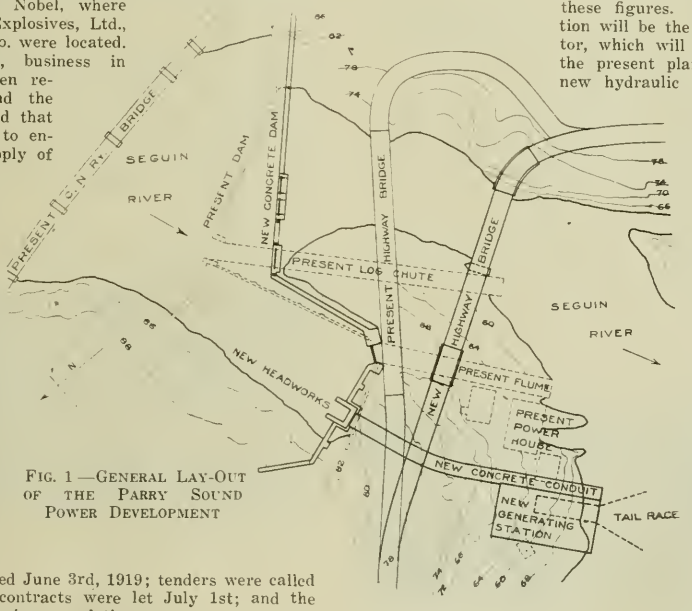

FIG. 1—GENERAL LAY-OUT OF THE PARRY SOUND POWER DEVELOPMENT

The vote was polled June 3rd, 1919; tenders were called to be in June 20th; contracts were let July 1st; and the power dam is now nearing completion.

For many years past the town has owned a small hydro-electric power plant, located very near the site of the plant now under construction. The old plant was rebuilt in 1905 and equipped with a Jenckes hydraulic turbine and an Allis-Chalmers-Bullock generator of 425 k.w. capacity. A concrete dam on the Seguin River was built at the same time, and also a timber storage dam at the outlet of Mill Lake. The town's power requirements are exceeding the capacity of this plant; moreover, the officials dislike being dependent upon a single unit; so, for these reasons, and also those outlined above, it was decided to build the new plant.

The Seguin river watershed, with an area of 425 square miles, includes at least twelve lakes well suited for storage purposes. Conservatively estimating the flow at one cubic foot of water per second for each square mile, with a gross head of 32 ft., 1,200 h.p. (24-hr. power) would be available. Assuming that the load factor of the system would not exceed 50%, the plant would produce 2,400 h.p. on peak, or about 2,250 h.p. of saleable electrical power, and upon these figures the design was based.

The engineers point out that a more complete study of the watershed, with its excellent storage possibilities, may show a capacity much in excess of these figures. The initial installation will be the old 600 h.p. generator, which will be transferred from the present plant and coupled to a new hydraulic turbine, and a new 800 h.p. unit, or a total of 1,400 h.p. By the time the third unit is required, more accurate run-off data will be available, and the third unit, instead of being 800 h.p., may be 1,000 or even 1,500 h.p.

The present plans, however, are for an ultimate installation of at least 2,200 h.p., of which 60 h.p. will be required for the operation of the motor-driven exciters, leaving a net saleable output of 2,140 h.p. This is not taking into account the generator overload capacity of 400 h.p. With the initial installation of 1,400 h.p., allowing 40 h.p. for exciters, the net saleable output will be 1,360 h.p., not including the generator overload capacity of 200 h.p. The generator station provides room for the installation of a third unit of any probable required capacity.

Between Mill Lake and the head water, there is 5 ft. difference in level. At the new development there will be a gross head of 32 ft. The difference in level between the new tailrace and Parry Sound, which is an arm of Georgian Bay, is 8 ft. It may be mentioned that there is a power development, owned by the Parry Sound Lumber Co., on the Seguin River between Georgian Bay and the town's plant.

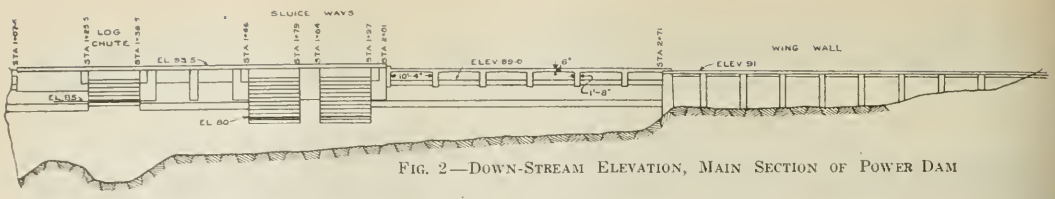

FIG. 2—DOWN-STREAM ELEVATION, MAIN SECTION OF POWER DAM

The engineers considered the possibility of building a higher power dam and thus obviating the necessity of a new dam at Mill Lake, and also increasing the working head. By raising the dam another 5 ft., a head of 37 ft. could have been obtained, but there would then have been a greater area under flood below Mill Lake. It was estimated that the land damages, including the necessary removal of the C.N.R. tracks, would cost more than the value of the additional power that would be obtained as a result of the higher head. It was thought that a much smaller sum would give as much

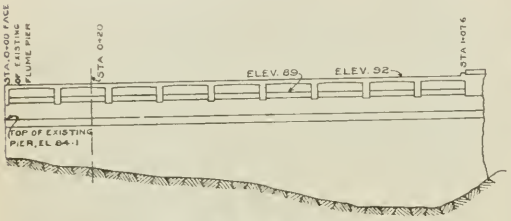

FIG. 3—SECTION OF POWER DAM BETWEEN PRESENT LOG CHUTE AND PRESENT FLUME

additional power if expended in other ways; that is, by stricter conservation of the waters of the upper lakes, thus increasing the possible average flow.

The town owns all the rights on the whole watershed, having looked forward for many years to its possibilities for greater power development, and having eventually acquired entire control. Employees of the town maintain all the dams on the lakes, and attend to their regulation.

The new power dam is being constructed immediately below the present dam, and has a good rock foundation. It will raise the water 6 ft. above the crest of the present dam. This will bring the water within 2.8 ft. of the C.N.R. bridge girders, or, in flood periods, to within 2 ft. of the

FIG. 4—OLD DAM AND HIGHWAY BRIDGE, LOOKING DOWN-STREAM

girders. It was hoped that the old dam might be utilized in the construction of the new works, but upon examination it was found that its condition did not warrant further use, and it has been entirely abandoned. The new dam is so placed that the present plant need not be shut down until the new plant is ready to be operated. The entire works will be constructed, ready for operation, before the final gap in the new power dam will be closed, shutting off the supply to the present flume. This is shown by Fig. 1. After the new unit is in operation, the old generator, exciter and

FIG. 5—NEW POWER DAM, LOOKING UP-STREAM

switchboard will be moved from the present plant to the new one and the present timber flume will be dismantled.

The dam is of solid gravity type. The crest has an overflow weir 160 ft. long, two sluiceway openings, and a log chute opening, these three openings being closed with stop-logs. In addition to these, there is a regulating sluiceway with a geared gate.

The present forebay, which has been very effective in taking care of ice, is being retained and the present flume opening will be used as an ice overflow and sluiceway.

With all the sluices and weirs, floods up to 5,000 c.f.s. can readily be passed, and this

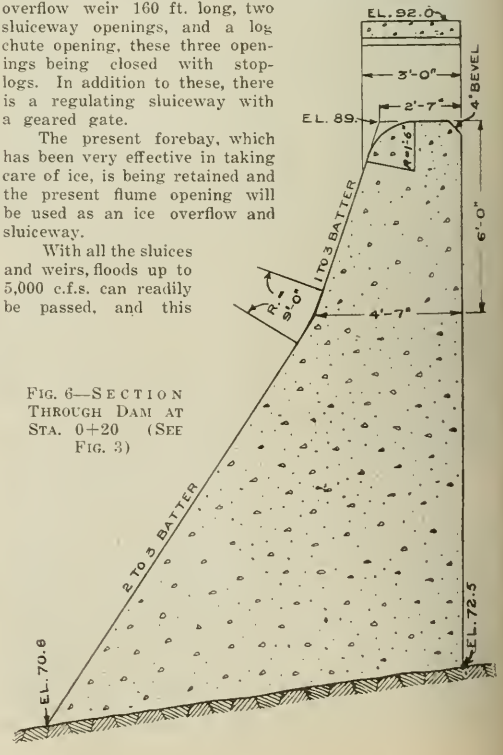

FIG. 6—SECTION THROUGH DAM AT STA. 0+20 (SEE FIG. 3)

flood capacity is said to be in excess of any flood likely to occur after the Mill Lake dam has been rebuilt and other storage dams have been put in place.

The headworks intake leads to a reinforced concrete conduit, box section, 9½ by 10 ft., through which the water flows to the power house. The intake is being equipped with gates, racks, ice and debris outlet, etc., and is housed.

The turbines will be set in open concrete flumes and will be of standard horizontal type, equipped with Lombard oil

FIG. 7—VIEW ACROSS OLD POWER DAM, SHOWING HEADWATER AT RIGHT AND LOG CHUTE

pressure governors. The generator aisle will be used only for the three generators. The switchboard gallery is raised 21 ins. above the floor and projects into the generator aisle, so that the operator will have a clear view of all equipment. The exciters are adjacent to the switchboard gallery. An overhead travelling crane will serve the generators and hoisting gear will be arranged for the flumes and for the erection and adjustment of the turbines. The switchboard will consist of generator and exciter panels, feeder panels, series street lighting panels, etc., and will be equipped with an automatic voltage regulator. The power house and gate house will be of reinforced concrete.

FIG. 8—NEW POWER DAM UNDER CONSTRUCTION

The Mill Lake dam will be replaced by a concrete dam of the same height, containing log chute, overflow weir, sluiceways and a submerged gate.

The road en route to Mill Lake will be flooded at one place as a result of the higher power dam, and this will require 6 ft. of fill for a length of 400 ft., and the construction of a culvert.

As can be seen from Fig. 1, there is at present an old highway bridge across the river just below the power dam. While the necessary new bridge could be carried on the power dam, that would entail considerable detour and steep grades. Bearing in mind proper town planning requirements, eliminating such detours and grades, it has been decided to build a new bridge, costing $15,500, below the present one.

Following are the costs as estimated by the consulting engineers, and it may be stated that all the contracts have been awarded within the estimates:—

Power dam, including sluice gates, etc., and cofferdams	$ 18,500
Head works, north wing wall, conduit, intake and water metering equipment	14,500
Generating station, flumes, gates and tailrace	32,800
Crane and hoist	2,500
Removal of flume, resetting log chute, etc.	750
Two turbines, one 1,050 h.p. for new generator, and one 650 h.p. for present generator, with governors, installed	19,200
Generator, 600 kw., installed	11,000
Resetting present generator and exciter	300
Motor generator exciter set	2,000
Switchboard, including rebuilding of present switchboard, wiring, etc.	6,750

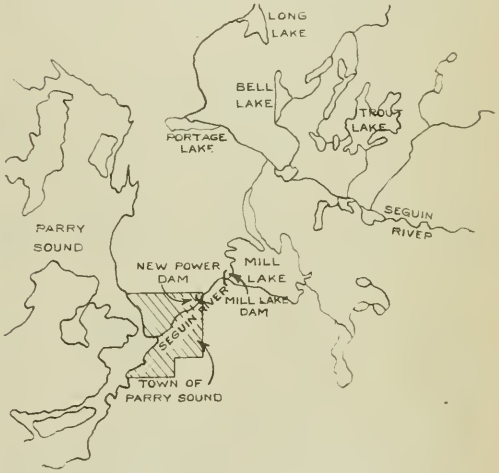

FIG. 9—MAP OF THE PARRY SOUND DISTRICT, SHOWING COURSE OF THE SEGUIN RIVER AND LOCATION OF NEW DEVELOPMENT

Voltage regulator	1,700
Mill Lake dam	6,500
Raising level of road and culvert	1,000
Allowance for contingencies	6,500
Engineering	7,000
Interest during construction	4,000
Land damages above power dam	15,000
Debenture issue	$150,000

(Six per cent. bonds sold at 101.75)

Annual Generating Charges

Following are the estimated annual charges:—

Annual charge on debenture issue	$ 11,250
Annual charge on balance outstanding ($30,000) on old debentures issued in connection with present power plant	2,225
Maintenance and repairs	3,000
Supplies, oils, etc.	500
Operation	3,600
Insurance	400
Annual generating plant charges	$ 20,975

With an output of 1,360 h.p. (neglecting the overload capacity) this would mean an annual power cost on the switchboard of $15.50 per h.p.

If the third unit be identical with the initial new unit, the cost on this installation will be, at present prices:—

Turbine with governor	$ 11,500
Generator	11,500
Switchboard and wiring	2,000
Total	$ 25,000

The additional storage capacity required throughout the watershed for supplying the three units, together with attendant land damages, is estimated at $25,000, or total cost of $50,000 for an additional saleable output of 780 h.p. (neglecting overload capacity). On this, annual cost would be $4,450; or for the 2,140 h.p., the total annual cost would be $25,425, or $12 per h.p. It is confidently expected by the engineers, however, that with extensive storage on the watershed, a greater power capacity would be available, and that the third unit could be larger without appreciable additional cost for machinery. For instance, if the third unit is 1,500 h.p. instead of 800 h.p., the additional cost over the above figures would be $20,000, on which the annual charges would be $1,600. This would yield 2,830 h.p. at a total annual cost of $27,025, or somewhat less than $10 per h.p. at the switchboard.

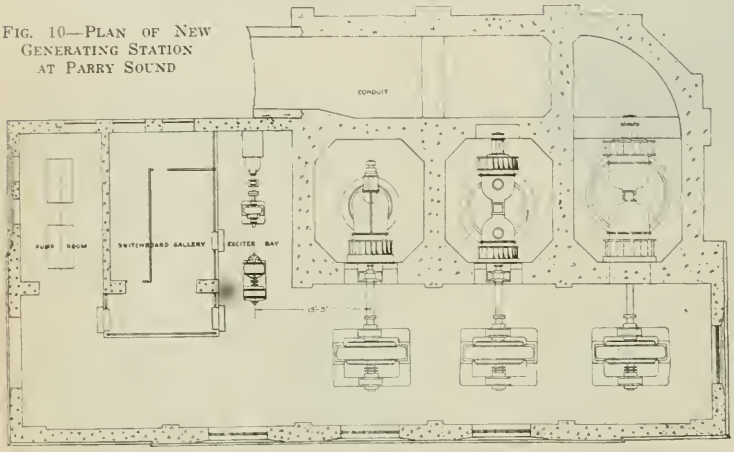

FIG. 10—PLAN OF NEW GENERATING STATION AT PARRY SOUND

FIG. 11—EXCAVATION FOR TAILRACE AT GENERATING STATION SITE

R. W. Harris is the resident engineer for C. H. and P. H. Mitchell, who are supervising the construction of the plant. Geo. Groves is superintendent of the Parry Sound Electric Light and Power System. The general contractors are W. M. Fletcher & Co., of Toronto; the contractors for the electrical equipment are the Canadian Westinghouse Co., Ltd., of Hamilton; for the hydraulic equipment, the Boving Hydraulic & Engineering Co., Ltd., of Lindsay.

TRACK LIFTED FOR MILITARY USE

OVER 23,000 tons of steel were lifted from the roadbeds in Canada during the war and shipped overseas, according to the report presented to the Dominion government by Alex. Ferguson, engineer in charge of lifting rails for war purposes. Mr. Ferguson's report follows:—

On the 21st of May, 1917, instructions were given to proceed with the work of lifting track from the roadbeds of the Grand Trunk Pacific and Canadian Northern railways, between Imrie and Resplendent, Alta., in order to provide steel rails for the use of His Majesty's armies in France. An organization was immediately created, and the work of lifting track and of transforming the two lines into one commenced.

The Grand Trunk Pacific track, between Imrie and Leaman Junction, 13.6 miles; between Obed and Pocahontas, 42.25 miles; and between Geikie and Resplendent, 34.8 miles, was lifted, and the rails and angle bars shipped to Three Rivers for shipment to France.

The Canadian Northern track between Leaman Junction and Obed, 79.9 miles, and between Snaring Junction and Geikie, 22.05 miles, was lifted and the rails relaid on the Grand Trunk Pacific roadbed, between Leaman Junction and Obed, and between Snaring Junction and Geikie, thus releasing the Grand Trunk Pacific rails and fastenings for war purposes as required by order-in-council.

The track of the Grand Trunk Pacific between Pocahontas and Snaring Junction was lifted and relaid partly with 60-pound steel and partly with 80-pound Canadian Northern steel in order to release the Grand Trunk Pacific steel for shipment to France, and at the same time preserve rail connection with the coal mines at Pocahontas. This portion of the Grand Trunk Pacific line is being operated as a spur and is, as yet, considered merely temporary. A rearrangement of the main lines may be found necessary in the interests of economy.

The first shipment of steel rails for Three Rivers left Edmonton on the 17th of June, 1917, and the last on the 26th of October, 1917. The total shipments amounted to 23,408 gross tons of rails and 1,110 gross tons of angle bars.

During the months of October, November and December, 1917, a considerable amount of work was done on the construction of highways between Otley and Carrot Creek, and between Peers and Fulstow, in order to give the settlers access to the Grand Trunk Pacific line. Before the close of the fiscal year arrangements were made for the completion of these roads and for the construction of a roadway from Rosevear, on the Grand Trunk Pacific, to Horner.

The tenders which were received last Monday by the Department of Public Highways, Province of Ontario, for the construction of about 65 miles of bituminous roads, have been opened and the contracts awarded, but the department states that it will be impossible to give out any information regarding the list of bidders, prices or names of successful contractors until the provincial cabinet has approved of the awards suggested by the department.

Water Power Policies of the Quebec Government

Goodwill of Ontario and Federal Officials Needed to Solve Some Difficult Problems—Emphyteutic Leases from 9 to 99 Years — Many Undeveloped Powers in the Province—Address at the Annual Meeting of the Union of Canadian Municipalities

By ARTHUR AMOS
Chief of the Hydraulic Service, Province of Quebec

CANADA'S water-powers! Quebec's water-powers! What alluring words, to a great many promoters; what promises, to a great many prospectors! One might almost think that a waterfall is as valuable as a gold mine. I might state immediately that such is not my opinion. Once a gentleman very much interested in water-powers and who had obtained a valuable grant from the government, came to my office and said: "I think that a power concession is merely an authorisation to spend a lot of money."

I do not agree with that statement either, although I do believe that a person wishing to obtain a water-power grant must be well organized financially and gifted with an energetic character and much perseverance in order to be able to realize a development. Anyone who has tried to acquire flooding rights will no doubt agree with that statement.

In my province there are still, of course, a great many undeveloped power-sites, both in the populated districts and northward in the great uninhabited New-Quebec.

Recently the Hydraulic Service was called upon to make a statement regarding the assets of Quebec in this regard, and it was thought proper to consider separately the power-sites that might be useful to the present generation and those that would only benefit our grandsons. This division line was fixed along the 50th parallel, so a glance at the map will show that we have practically admitted that more than two-thirds of the powers of the province are out of reach for the time being.

Incidentally, I was not quite right in doing so, for we have actually issued a lease for a water-fall near the 57th degree of latitude, about as far north as the middle of Hudson Bay!

Nevertheless, we have roughly estimated the energy of the water-falls below the 50th parallel to represent, in round figures, 5,000,000 h.p. If we assume that the remainder of the province is equally well provided with water-falls, it would then have some 10,000,000 h.p. scattered in the wilds of the Labrador and Ungava districts; but these figures are merely hypothetical, and personally I do not attach great importance to them; I believe rather that we had better concentrate our thoughts and abilities on the sites that are at our very doors and waiting on our initiative to supply us with all the commodities that their energy represents.

Two Classes of Rivers

To that end, the concurrent goodwill and best brains of our governments, at Ottawa and at the provincial capitals, must unite in order to find the means of solving the many difficult problems that are involved.

As you know, rivers are of two classes, the navigable ones and the non-navigable. Although this division is simple enough, yet innumerable disputes have from time to time arisen owing to the difficulty of getting a correct definition of what is a navigable stream. For instance, I may mention the case of the Ottawa river, which was declared navigable near Ottawa, at Table Rock, only by three judges against two, in the Appeal Court. If a river be navigable, then its bed is vested in the provincial government, notwithstanding the fact that the federal government controls the works that may be built thereon.

Consequently, any applicant for power on the St. Lawrence, the Ottawa or the Saguenay, for examples, must negotiate with at least two governments. In the case of the Ottawa river, the third government, that of Ontario intervenes, as this river is the interprovincial boundary.

It may therefore be seen that it would be desirable that as regards such rivers, a uniform policy should prevail, and that similar conditions by the three authorities would be of great advantage to prospective users. Possibly, however, it would be better not to discuss difficult cases but preferable to state what is done regarding other rivers where only one government has charge.

I have stated that the rivers are divided into two classes, navigable and non-navigable. The beds of non-navigable rivers are either private property or form part of the public domain. Before 1884, the Quebec government granted land lots bordering rivers without any special reserve in regard to the water rights adjoining these lots. It followed that when a settler had obtained his letters-patent, he became *ipso facto* proprietor of half the adjoining stream. In consequence a good many water-falls thus passed into private property and were developed at an early date. In 1884, owing to disputes for water rights, the government became aware of the value of water-powers, and a law was passed creating a reserve, in favor of the Crown, three chains in width (about 200 ft.) along all non-navigable rivers.

The result was that, remaining riparian owner since that date, the Crown retained all rights in the bed of streams, and its leases on such rivers do away with many former troubles. To give a short account of these government leases:—

History of Quebec Leases

Originally (about 1867) the sites were sold outright for practically a nominal sum as mill sites. Then, some thirty years later, or about 1897, somewhat more severe conditions were imposed and prices were raised a great deal. Such was the case of the great Shawinigan Falls, sold for $60,000 with the obligation of spending $3,000,000 within a few years. Then about 1909, the principle of the emphyteutic lease began to be applied, and since that time has been generally adopted almost to the exclusion of sales.

I do not know whether emphyteusis is well known outside of the province of Quebec, so I will explain what it means in a few words. It is a contract by which the proprietor of an immovable, conveys it to another for a time which cannot be shorter than 9 years nor longer than 99 years, the lessee binding himself to make improvements, to pay the lessor an annual rental, and to pay such other charges as many be agreed upon. This sort of lease differs from other leases by the fact that the lessee (provided he fulfills his obligations) becomes the real proprietor of the object conveyed, to all intents and purposes; he can sell or mortgage the property, and make any improvements he wishes. At the end of the lease the lessor takes back the property, as well as the buildings thereon, and may then enjoy all the improvements made unless he wishes to renew his contract. I shall not further discuss emphyteusis, as full details may be found in the civil code.

Such has been the policy adopted by the Quebec government for the last ten years and the public seems to like it. Rentals from those leases have been growing from year to year. In 1914, they amounted to $10,000; they reached $72,000 in the last fiscal year.

There is also another important source of revenue derived from rivers; it is the so-called stored water. There are several regulating reservoirs in the province. The first ones were built by the Public Works Department in the upper Ottawa, at the foot of Lake Temiskaming, at the foot of Lake des Quinze, and at the two outlets of Lake Kipawa. The others were built by the Quebec Streams Commission at the headwaters of the St. Maurice, at the outlet of Lake St. Francois, and a smaller one on the Ste. Anne de Beaupré River.

The St. Maurice River reservoir, which has lately been named the Gouin reservoir, is by far the largest of all. In fact it stores more water than is held by the Assuan dam built by the Imperial government on the Nile. So far it has permitted the commission to double the minimum flow of the St. Maurice, in accordance with its contract with the mill owners; and I have reason to believe that it will be possible to increase substantially this proportion.

The project cost about $2,500,000, including various accessory works such as a hydro-electric plant capable of developing 1,000 h.p., a railroad 20 miles in length, etc. This reservoir is at present yielding a revenue of $191,000 per annum just from the three companies now using it.

Storage Profitable for Province

After subtracting interest on the capital and an annuity for a sinking fund to redeem our bonds in 30 years, we had this year a net profit of about $25,000. Bearing in mind that there are still many rapids and falls available on the river, and that several of them will likely be developed in the course of the next 10 to 15 years, it may be seen that the proposition is a good one both for the government and for the users of the water.

The method adopted to collect the revenue was based, after mature consideration, on the horse-power-year. This expression needs a word of explanation. The minimum flow occurs in the fall and again in the winter months. The reservoir is consequently closed some months in the year and only opened in times of drought. The water given out in those dry months is calculated as though it was evenly distributed throughout the year; by a simple calculation it may then be converted into horse-power according to the head at each power-house. Such is at present the policy of the government as regard water-power and storage reservoirs.

I have not referred at any length to the undeveloped water-powers of Quebec for the reason that I have treated the subject already in a little booklet entitled, "Water-Powers of the Province of Quebec," which was printed in 1917, by the Department of Lands and Forests of the Province of Quebec, and which will be mailed free to anybody applying for it.

Permit me to sum up the situation by saying that the province of Quebec is well provided with water-powers, as is well known, but that most of its falls are not of great height.

It should be especially observed that the sites where considerable energy (over 50,000 h.p.) can be produced, and which are still in a natural state, are remarkably situated for supplying the wants of the principal cities. Thus, for the vicinity of the city of Ottawa, we find the Chats Falls and other rapids of the Ottawa River; for Montreal, besides the sources of energy now in use, the rapids of the St. Lawrence at Coteau, Les Cèdres, and also the Sault-Saint-Louis, commonly called Lachine Rapids; for Trois-Rivières and Quebec, the water-powers of the River St. Maurice, regulated by the largest reservoir in Canada; for the Saguenay and Chicoutimi region, the rapids of the Grand-Décharge, the outlet of Lake St. John; and lastly, for Lower St. Lawrence, the falls of the Manicouagan and of the River Aux Outardes.

Wonderful Opportunities at Lake St. John

The south shore of the St. Lawrence is not so well provided, but it may be said that for the more densely populated regions, that is to say the Eastern Townships, the St. Francois River, which is regulated, will suffice for the demand for a good many years.

The advantages of the Lake St. John region and, particularly, those of the Grande-Décharge, should be especially emphasized. The national conditions there are remarkable; the available undeveloped power is enormous; ocean navigation is possible almost as far as the site where the works would be erected; there is no lack of labor and a railway, as well as a steamer line, connects the district with Quebec and Montreal.

The Quebec Streams Commission, acting under the jurisdiction of the provincial government, has taken in hand the improving of the regimen of rivers on which industries are established. Great advantages are anticipated from this policy, and everything tends to show that within the next decade the work of this body will produce all the good results expected from it.

The question of public ownership is very much to the fore these days. I do not think, however, that it is within my jurisdiction to discuss this matter here, although I may say that the Quebec government has already made grants to a certain municipality on the general policies outlined above So far as I know, this has been found satisfactory to the people of the town concerned, and no other special favor has been asked. I would be pleased to furnish anyone privately with any further details that might be desired, concerning the water-power situation in the province of Quebec.

Letter to the Editor

PROF. BLANCHARD'S APPOINTMENT

Sir,—I wish to advise your readers of the action of the Board of Regents of the University of Michigan in the matter of reorganization of the work in highway engineering at Michigan University.

At the last meeting of the board, the professorship of highway engineering was created and filled by the appointment of Prof. Arthur H. Blanchard, late of Columbia University. Prof. Blanchard is so widely known as a teacher and engineer in matters of highways and highway transport, that I need say nothing as to his qualifications.

Funds were also provided for the appointment of an assistant professor of highway engineering who will have charge of the highway laboratory and courses in design, laboratory and field work. This position will be filled by the appointment of John H. Bateman, a graduate of the University of Michigan, and for the past four years assistant engineer and engineer of the Michigan State Highway Commission.

The regents have made liberal appropriations for equipment, current expense and for the salaries of clerical and laboratory assistants.

The University of Michigan four years ago commenced to develop work in highway engineering, and the work in the university and the laboratories has been built up to a good state of efficiency under Prof. John J. Cox, who recently resigned to devote his whole time to construction work.

A large program of work under Prof. Blanchard will include the continuation of all work formerly given undergraduate students in highway engineering, together with one or two new courses, the addition of courses in highway transport and highway economics, the development of graduate work during the regular collegiate year, and the continuation of the highway short course which has been given at Michigan University for the past five years.

In addition to this work, special courses for graduate practicising engineers, leading to the master of science degree in engineering, will be given during the winter months. These courses will be given intensively so that engineers who can only take a few months away from their practice may take the work and secure credit towards the degree.

It is the intention and desire of the authorities of the University of Michigan to give the most ample support to the work in highway engineering as being a subject which demands attention at the present time.

HENRY E. RIGGS,
Professor of Civil Engineering,
University of Michigan

Ann Arbor, Mich., August 13th, 1919.

The Rust Engineering Co., of Pittsburgh, Pa., have been awarded contract for a radial brick chimney for the Ames-Holden Tire Co.'s plant at Kitchener, Ont.; also contract for four chimneys for the Imperial Oil Co.'s refinery at Dartmouth, N.S.

HORSEPOWER REQUIREMENTS OF CENTRIFUGAL PUMPS

THE water horsepower requirements of a centrifugal pump may be easily determined when the quantity to be pumped and the total head are known. However, it is necessary to have some idea of the efficiency of different sizes and kinds of pumps before the actual horsepower for the driving motor can be specified. Useful information on this subject is given by T. M. Heermans, mechanical engineer, centrifugal pump department, Allis-Chalmers Manufacturing Co., in a recent issue of "Power," from which the matter following has been taken.

The efficiencies in the accompanying table are conservative and can be used in estimating the horsepower required for well-designed pumps operating at suitable speeds against moderate heads.

The usual practice in fitting motors to centrifugal pumps is to allow 10% leeway over the horsepower that it is figured will be required.

Starting Requirements

Besides knowing the size of motor to put on a pump, it is necessary also to know something about the starting requirements of centrifugal pumps and how they affect the selection of the type of motor and also the starting apparatus to be used. Centrifugal pumps are started up quite easily and are generally considered "light starting duty for a motor." Consequently, squirrel-cage motors, and even synchronous motors that do not have much starting torque, can be used to drive centrifugal pumps, but this statement needs a little explanation. The curves of Fig. 1 are typical of the performance characteristics of three different types of centrifugal-pump runners. Chart A is for a standard single-stage centrifugal pump fitted with a runner having a rising horsepower characteristic. By slightly changing the runner design, this pump can be made to have a horsepower curve that is practically flat after the point of maximum efficiency. Chart B is representative of the ordinary type of multistage pump with diffusion vanes, and chart C shows the characteristics of a single-stage pump with a so-called Francis type runner which is particularly designed so that relatively high pump rotative speeds can be employed for low heads. These curves have been reproduced to show in particular the "shutoff horsepower" of different kinds of pump runners. This is the power required to rotate the pump runner at rated speed in the pump casing when full of water but when no water is allowed to be discharged, as would be the case when the pump is started up with the valve in the discharge from the pump closed. The shutoff horsepower has been indicated as a certain percentage of the horsepower required at the highest point of the curve, which has been taken as 100%.

CONSERVATIVE EFFICIENCIES FOR PUMPS OF VARIOUS CAPACITIES

Size of pump In.	Normal capacity, G.P.M.	Efficiency single-stage heads up to 150 ft. Per cent	Efficiency multi-stage heads above 150 ft. Per cent
2	100- 150	50	45
3	200- 350	55	50
4	400- 600	60	56
5	650- 900	65	62
6	950-1,300	70	68
8	1,500-1,800	72	70
10	2,000-3,000	75	72
12	3,500-4,500	76	73
14	5,000-6,500	77	74
16 and over		78	75

Slip-ring or shunt-wound direct-current motors will start pumps having the characteristics shown by all three curves, and squirrel-cage motors also have been found capable of starting these pumps, although in the larger sizes and sometimes for pumps having the characteristics shown by chart C, squirrel-cage motors will take too much current in starting to be used. Standard synchronous motors will ordinarily start pumps having the characteristics of chart A, and develop the necessary torque to pull into synchronism when up to speed, but will have to have specially constructed motors to develop the 50% of rated horsepower required to pull pumps having the characteristics of chart B into synchronism, and cannot be used at all, except by making special arrangements, to start pumps having the characteristics shown in chart C.

The special arrangement just mentioned is to equip a pump so it can be started up empty and then primed after being brought up to synchronous speed. What is done is to provide some means of lubricating the close clearances in the pump until it can be primed, when the water will provide the lubrication. The necessary arrangements can be made easily on single-stage pumps, but it is rather difficult to fix up the multistage type. For this reason they are seldom started up empty, although clutches are sometimes employed.

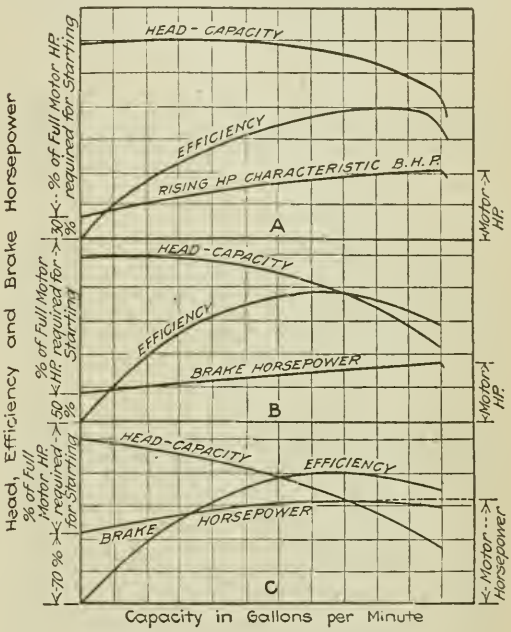

FIG. 1—PUMP CHARACTERISTIC CURVES

All the previous remarks apply to pumps that are started up with a closed valve in the discharge. As a general rule this should be figured on, as otherwise starting conditions will be much worse. It is necessary only to refer to the curves again to see that where no discharge valve is provided, the motor in coming up to speed has also to come up to full horsepower and be thrown on the line at full rating instead of at a fraction of full horsepower. This is not good practice and is bad for the motor even if undue disturbances will not be caused in the line. Instances have been known where the heavy surges of current to start squirrel-cage motors attached to centrifugal pumps without any valve in the discharge have in time loosened up the motor coils.

Kinds of Motors Used

Having considered the power required to start and operate centrifugal pumps, brief reference will be made to the kinds of motor used for pump drive. This is a large subject in itself and should be taken up in detail in separate articles. Probably the motor most commonly used to drive centrifugal pumps is of the squirrel-cage induction type. This motor,

on account of its simplicity and also because the starting duty of a centrifugal pump is not heavy, is used to drive the majority of small and moderate-sized pumps.

In sizes over 150 h.p. and in many cases less, the slip-ring induction motor is used instead of the squirrel-cage type, because it takes less current from the line in starting. Also power companies often fix the maximum size of squirrel-cage motor they will allow to be connected to their lines. In still other cases where a system does not have much capacity, throwing a large squirrel-cage motor on the line would cause serious disturbances and possibly a voltage drop that would be enough to prevent the motors coming up to synchronous speed. These cases call for the use of slip-ring motors. This type is used sometimes when a moderate amount of speed control of the pump is required, possibly to maintain a constant pressure with a variable discharge or to maintain a constant discharge with varying heads.

High-Speed D.C. Motors

Direct-current motors as well are used where speed variation is required, but for constant-speed service are not used so much as induction motors. Then, too, for moderate heads standard centrifugal pumps ordinarily run at higher than the best direct-current motor speeds. However, relatively high-speed direct-current motors are now being built that can be used as satisfactory pump drives where only direct current is available.

As a fourth kind of pump drive, synchronous motors are just beginning to receive deserved attention. Many centrifugal pumps, because they offer a constant steady load, present a fine opportunity for using a large synchronous motor to keep up or correct the power factor of a power system, and by using proper care suitable synchronous motor-driven centrifugal pumps can be often selected.

Troubles Traceable to Pump

Before leaving the subject of the horsepower requirements of centrifugal pumps as related to motor drive, possibly it will be well to point out a few troubles that are sometimes encountered with motors and that are traceable to the centrifugal pump. The most common difficulty, which has been mentioned previously, is operating an improperly selected pump at less than the rated head. This will overload the motor and cause it to run hot. Another trouble almost as common is pump and motor out of alignment due to improper erection. This causes vibration and hot bearings and wears out rapidly the coupling bushings. A third trouble sometimes experienced and resulting in hot motor bearings, is when the centrifugal pump develops an end thrust, causing collars on the shaft to rub on the ends of the bearings. End thrust may develop in a single-stage double-suction pump on account of one side of the runner becoming partly obstructed or an obstruction lodging in the suction passage on one side, which unbalances the runner. Unequal wear of the runner wearing rings on opposite sides of a double-suction runner or displacement of the runner slightly to one side of the centre line of the casing also will cause thrust. In multistage pumps thrust is generally caused by failure or partial failure of the arrangements provided to balance the end thrust. Two pumps taking their suction from the same suction pipe or discharging into the same discharge line, if they are not properly arranged and do not have the right kind of characteristics, can cause trouble by dividing the work unequally, but this and similar questions are outside the scope of this article.

Unit Considered in Entirety

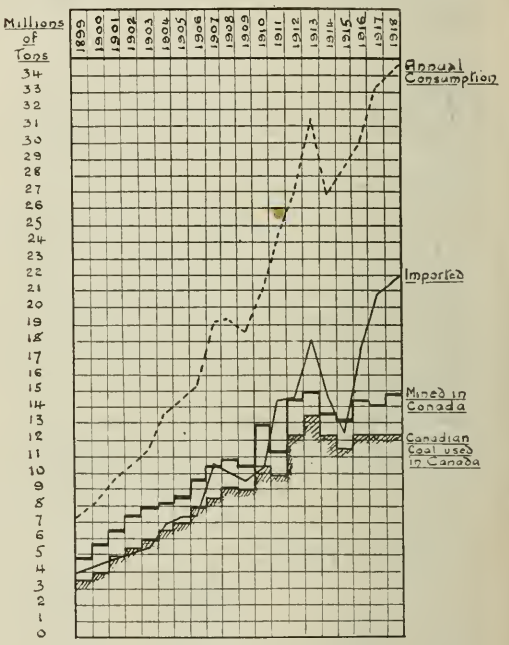
It can be safely stated that a pump should not be bought merely as a pump of a certain size without any reference to the work it will have to do. In conjunction with the driving motor it should be selected to do certain definite work to the best advantage. It is therefore preferable to buy pumps that have been tested carefully and their characteristics determined, with motors of suitable size to run the pumps under all the conditions that will be met with in service. That is, a pump and the drive should be considered as a unit and selected accordingly.

PRODUCTION OF COAL IN CANADA*

By F. D. Gray

THE accompanying graph was compiled from Department of Mines statistics. It shows that up to about 1912 the Dominion was able to furnish from its own coal-seams a little better than half the tonnage of coal consumed for all purposes in Canada. Actually, however, this was not the case, as a certain amount of coal was exported, chiefly from the Cape Breton mines to Boston, Mass.

During the period 1886 to 1899, the coal imported into Canada averaged a little over 54% of the total coal consumption of the country. During the period of 1899 and 1918, included in the graph, the same percentage was maintained, but during the war period the percentage of coal imports was greatly increased. At the present time the imports have risen to 63% of Canadian consumption of coal.



Production and Consumption of Coal in Canada

The coal consumed in Canada during 1918 is estimated at 34,840,000 tons, the highest figure recorded in Canadian statistics, and most closely approached by 1913, when 31,582,545 tons of coal were consumed.

The consumption per capita shows a steadily rising figure, and this is encouraging as showing Canada's progress in the industrial arts and in the conveniences of civilized life, but the discouraging feature disclosed by a study of the statistics is that the Dominion is rapidly increasing its importations of coal, at higher prices than have ever prevailed in the past, and at the same time the home production of coal shows a stationary and even a declining tendency. Any form of production in Canada that is stationary is unsatisfactory and is equivalent to a declining production when viewed in relation to the general growth of population.

There is a difference between the jump in coal consumption that marked 1913, and the peak figure of 1918, namely that in 1913 Canadian coal-mines were increasing their outputs coincidentally with the increase in coal im-

GENERATOR FIRES*

ONE of the side issues brought into existence by the sustained overloads carried during the war service, is the question of fires, their origin and the best means of handling them, and in view of this, a questionaire was circulated by the sub-committee of the N.E.L.A., early this year, giving the following results:—

Some 30 companies reported 81 fires in the past five years; 21 fires equally divided between 60 and 25 cycle units, were specifically described occurring in units ranging from 3,300 to 35,000 kw., and from 2,300 to 13,200 volts.

About an equal number of fires appeared to have started within the insulation and external to the insulation. The greater proportion of fires external to the insulation seems to have occurred on 3-phase systems operating without a grounded neutral. Other causes are many, principally short circuits and grounds, with the remainder from mechanical causes, eddy currents, moisture, etc.

The consensus of opinion is that more frequent inspection and cleaning of the generators is very desirable and has a direct bearing on the liability to fires from sources external to the windings. Too many companies appear to trust the air washing devices for this work, but even with the best possible apparatus, air and grease creep in, fluff and dirt accumulate and conditions for potential fires exist. Good practice, therefore, would indicate periodical cleaning.

Grounding of the Neutral

The grounding of the neutral of 3-phase systems solidly or through resistance, is rapidly becoming standard practice on both 25 and 60 cycle throughout the country.

Twenty-one of the 30 companies replying favor this method of operation; five operating with solid ground system prefer to operate through resistance; three companies oppose the grounding of the neutral. The consensus of opinion seems to be that grounding is very desirable and, in addition to other advantages, has a considerable effect in the reduction of generator fires occurring external to the insulation of the conductors.

It is also rapidly becoming standard practice, particularly on large units, for the manufacturer to bring out both ends of each phase winding to the generator terminal board so as to permit the installation of current transformers between the terminals of phase windings and the neutral of the coils. The current transformers can be connected differentially with respect to the instrument current transformers in the leads between main oil switch and generator, so that in the event of a fault in the generator or its leads, the balanced relay will immediately open the main oil switch, the neutral switch if closed, and, after slight delay, the field switch.

Twenty-four of the 30 companies reporting approve the installation of balanced relay protection and have adopted it as standard practice on all new generator installations and on older generators where the expense involved is not too great.

Fires in Turbo-Generators

The modern type of turbo-generator is usually completely enclosed and the blower action of the ventilation is such that fires are apt to become serious and very difficult to extinguish. As in the case of most fires the time element is the main factor in control. It is especially important to apply the extinguishing medium as promptly as possible, and as close to the seat of trouble as can be done without permanent injury.

This leads to the question of ways and means of fire fighting. Water, steam and carbon-tetrachloride are looked upon with favor, the standard ways of applying being to pipe these mediums up to the end bells.

*Excerpt from annual report of the Canadian Electrical Association's Committee on Electrical Apparatus. Members of the committee: J. F. Neild (chairman), W. H. McIntyre, C. J. Porter, M. D. Schwegler and J. S. H. Wurtle.

PRIVATE WELLS AND PRIVY VAULTS*

By Robert E. Tracy
Director, Bureau of Governmental Research, Chamber of Commerce, Indianapolis, Ind.

IT is a far cry from the privy council to the privy vault, and still they are both Anglo-Saxon institutions dating from time immemorial, and both, as institutions, are very much alive and kicking in the 20th century. It would appear, however, that in England, the home of the privy council, that the privy vault was, comparatively speaking, very much eliminated or reduced to a state of innocuous desuetude by good sanitary methods. By the time we reach England's death rate from typhoid fever we can very well say the same of ourselves, but not until then. Why we should speak of the private well and privy vault, strikes me as rather strange so far as the adjective is concerned. If there was really such a thing as a private well, or a private vault, or a privy well, or a privy vault, in the literal sense, I should not be reading this paper to-day. In fact, we find that the well and the vault are often so close together that there is a certain ineffable unity which produces a result to the community which is, so to speak, ineluctable.

Disease Not Private Matter

The fact is that disease is not a private matter. Health is not a private matter. It is something that concerns the whole life of the community, and the neglect of which becomes a community liability, if not a scourge. One of the most serious preventable diseases we have to deal with is typhoid fever. It is a purely preventable disease, as the experience of our army on the Mexican border and in the cantonments, has shown beyond a doubt. Nevertheless, in 1916, in the 29 cities of over 200,000 population, Indianapolis was the worst sinner, in the number of reported cases per 100,000 population. Our rate in 1916 was 26.6, the highest on the list. In 1915 the rate was not so high, 12.3, and three cities, Columbus, New Orleans and Baltimore, were slightly higher, but in the five-year period, 1911-15, Indianapolis had an average rate of 20.5. Only two cities were worse, New Orleans with 20.9 and Baltimore with 23.7.

City Government Survey Report

The survey report of the city government, prepared in 1917 for the Chamber of Commerce, by the Bureau of Municipal Research of New York, has this to say on the subject: "The main causes of this condition are undoubtedly the pollution of the stream by sewage and the large number of yard privies. It is understood that a sanitary commission has been appointed to deal with the former nuisance. Two other sources of danger, namely, water and milk infection, are being eliminated by chlorination and filtration of city water and pasteurization of milk. The health department has not the power to compel householders to make sewer connections, even if sewers exist, or to prescribe a sanitary privy.

"It can, however, keep its information as to cesspools and unsanitary privies in a readily comprehensible form by carding this information and filing the cards by streets. It can also constantly agitate the question and insist that an ordinance be enacted making house connections with existing sewers compulsory upon orders from the board of health and requiring that in any future extension of sewers through built-up sections the sewer connections be made by the city and the cost be assessed upon the property owner and paid for by instalments, as other assessments are paid."

Typhoid Statistics

In 1917 there were 161 typhoid cases reported and 28 deaths; in 1918 there were 86 cases reported and 19 deaths. These statistics are not as accurate as they might be, even as to deaths for occasionally the case might develop into terminal pneumonia and death might be ascribed to this cause. It is fairly safe to say that there are ten times as

*Excerpts from a paper read before the American Water Works Association.

many cases as there are deaths, which would make 280 cases in 1917, as against 161 reported, and 190 cases in 1918 as against 86 reported.

The Privy Vault Menace

It it unnecessary for me to go into the causes of typhoid; they are perfectly well known. The existence of the disease in any strength, indicates that there are a number of human hogs about. Human filth transported from its place of deposit into the food of healthy people means typhoid.

It is estimated that there are 10,000 to 15,000 privy vaults in existence in the city of Indianapolis; many of these are on unsewered streets and the best that can be done is to see that they are screened and constructed in such a way as not to be accessible to flies, and not to be accessible to surface drainage, which causes soil pollution.

We are not the only city with such sources of public infection. St. Louis, in 1915, still had 20,000 privies, or privy sinks, 80 per cent. of which were on sewered streets. Philadelphia had 20,000, of which 10,000 had sewers accessible; Minneapolis had 17,000, Cincinnati 27,000. Toronto abolished 12,291 privy vaults in two years up to December, 1914; Philadelphia abolished 16,661 in two years. Worcester, Richmond. Buffalo and Erie report no vaults, but they are the great exceptions.

One of the objections to the elimination of these obnoxious places is the expense involved either to connect them with sewers or to place proper facilities in the interior of houses. This could be unquestionably worked out and installed just as gas or electric ranges are installed, in this case at the expense of the city, which would be repaid by the landlord over a period of months or years, as the case might be. We, in Indiana, have the Barrett Law, which furnishes us with the analogy for the carrying out of this health preventive campaign.

Deaths From Preventable Causes

About a million and a half persons die annually in the United States; probably 25 per cent. to 33 per cent. die from preventable causes. From 35,000 to 50,000 die annually of typhoid fever; from 400,000 to 500,000 are prostrated by this dread disease. Let us compare this with the figures of other countries:—

	Deaths	Sick
France	10,000	100,000
England	8,000	80,000
Germany	5,000	50,000

This comparison shows very plainly where we stand in the matter of public cleanliness. Bridgeport, in 1910, was the only American city having a death rate from typhoid of less than 5 per 100,000. Can we afford, as a nation, to permit the economic loss from sickness which runs from $1,500,000,000 to $2,000,000,000 a year, to continue? In 1908 Dr. Ditman wrote, "The cost of typhoid fever each year in sickness and death throughout America amounts to many million dollars. The sickness and death from this cause in this city and in Philadelphia, Scranton and Pittsburgh, during a single year, represent an economic loss to those cities of $3,750,000; such epidemics with their resulting losses, are startling in an age which considers itself enlightened."

Typhoid Disease of Uncivilization

Typhoid is the disease of uncivilization. As Sedgwick says, "Defective sanitation is but another name for defective civilization." The average rate from typhoid throughout the United States per 100,000 is 22. In Indiana as a whole, it is 40. The average for a ten-year period is far greater.

With 30,000 deaths per year from typhoid, the yearly loss is easily $150,000,000. It is just as stupid for us to permit this loss to continue as it is to permit our tremendous fire losses to continue, but just so long as ignorance and indifference create this disease politic, we shall continue to have it. According to Dr. Morgan, of the city board of health, the number of private wells is 308 and of privy vaults 664 within the mile square in this city (Indianapolis). You will probably be startled to ascertain the number of each, but this is based on a sanitary survey recently made and shows conclusively that we are sitting on a volcano so far as typhoid is concerned. As Lawrence Veiller, secretary of the National Housing Association, says, "How profitless is it for a city to spend vast sums of money to insure a supply of pure water to its inhabitants, and at the same time to allow barbarous privy vaults, sinks of iniquity, to drain their contents into private wells, still used by 'conservative citizens', who cling to them with startling tenacity."

When you stop to consider that during the epidemic of 1916, at the rate of $300 as an average cost of medical care per case, it cost the citizens of Indianapolis in the vicinity of $250,000. Without attempting to estimate the economic loss to industry, one can readily grasp the financial significance of further temporarizing with middle-age sanitary facilities.

Proper Ordinance Needed

This condition can be eliminated by the right kind of an ordinance, which, once backed by an enlightened public opinion, will go through without any difficulty. "There never was a reform in administration in this world," says Elihu Root, "which did not have to make its way against the strong feeling of good, honest men concerned in existing methods of administration, and who saw nothing wrong. It is no impeachment of a man's honesty, his integrity, that he thinks the methods that he is familiar with and in which he is engaged are all right. But you cannot make any improvement in this world without over-riding the satisfaction that men have in things as they are, and of which they are a contented and successful part." Mr. Root here states admirably the position of those who want to stand pat in health matters, and want to stand pat in this matter of privy vaults, because it involves a few of their dollars.

Have we not learned among other things, in this war that human lives come before dollars, that we are spiritual beings first and human beings second? We must become as interested in the conservation of human life, at least as interested as we are in the conservation of animal life, and surely in a great agricultural state like this, we do not neglect our stock. Human life seems so cheap after a great war when 7,000,000 men fell that others may live in freedom. Surely after this tremendous drain on the world's stock of humanity we can leave no stones unturned to preserve what the war has left intact, and fortunately we, in the United States, suffered almost no loss as compared to our annual loss from preventable disease. Our total deaths in this war was only twice our annual loss from typhoid.

New Spirit in Industry

In closing, let me quote from a statement of the Minneapolis Civic and Commerce Association, substituting the word Indianapolis for Minneapolis:

"A new spirit is developing in industry, a spirit of a realization that all industry suffers through the misfortune of any factor. The employer fails to prosper as his men fail to prosper. Bad housing for the workmen means bad business for the one who hires. In the light of this spirit, the primary question is not 'What can the tenant afford?' It is, 'What can Indianapolis afford?' If we are to develop in Indianapolis the highest type of civilization, if industry is to thrive permanently, if art and music are to serve their highest purpose, we must first recognize as an essential prerequisite to the realization of these high ideals, the providing of a home life for every family, rich or poor, that shall insure to them their inalienable right to sanitation, safety, ventilation, privacy, sunlight, space and beauty."

Official announcement is likely to be made at an early date of the appointment by the Dominion government of an Honorary Advisory Highway Board which will assist the Department of Railways and Canals in formulating its good roads policy for the enactment of the legislation, recently passed by parliament, appropriating $20,000,000 for federal aid for highways. Daily newspapers report that there are rumors in Ottawa that C. A. McGrath, chairman of the Canadian section of the International Joint Commission, will be a member of the board, and that Home Smith, of Toronto, and J. P. Mullarky, of Montreal, may be appointed.

PROGRESS IN WATER-TURBINE DESIGN

Excerpt from Annual Report of Canadian Electrical Association's Committee on Prime Movers. Signed by S. Svenningson (Chairman), A. H. Wilson and A. J. McDougall

DURING the four or five years period prior to the war the manufacturers of hydraulic turbines made great strides in developing units of high efficiency and simple designs. This was primarily obtained through the introduction of the high specific speed single runner units. During this period a great number of low head plants were built using single runner units of larger size than anything previously attempted. During the last four years, however, the activities in hydro-electric developments were greatly lessened and few new features in design have come out, although a certain amount of research work has been carried out the benefit of which should be realized in the near future.

Efficiencies of 92 to 93% for runners have already been obtained in several plants and we may assume that this is very near the maximum efficiency that can be expected; but, in order to obtain a maximum overall efficiency of plants, hydraulic turbine engineers are now carefully looking into the design of all passageways from headrace to tailrace. Particular attention is being paid to the design and efficiency of draft tubes for high specific speed runners. The tendency is towards the use of deeper draft tubes with the idea of making the turn from the vertical to the horizontal direction at lower velocities than was previous practice.

It is also generally realized that improvements can be made in the design of intakes, especially for low head plants.

There seems to be a difference of opinion as to the number and size of units to be installed in a projected plant; the tendency has been to look upon the water turbine as an almost fool-proof piece of machinery; consequently, plants have been equipped with as few and as large units as possible, thereby making considerable saving in first cost as well as operating expense. Considering, however, that the reliability of a unit does not only depend upon the water turbine but also on the generator and auxiliaries, some designers of power plants incline towards comparatively small units with less chance of shortage of power in case of breakdowns. The question as to size and number of wheels to be installed in a plant must, of course, also be decided upon with regard to the transmission system and importance of continuous service.

Runners

The single runner vertical shaft units for low and medium head plants have proven to be of such a success that practically all new plants under this category are now being equipped with this type of units.

Turbine manufacturers are constantly experimenting with higher specific speed runners in order to meet the demand from customers for large units operating under low heads. While a few years ago a specific speed of 100 was considered high, manufacturers claim to-day to be able to build low head units with a specific speed of 170.

Thrust Bearings

With the increase in size of large vertical water wheels and the consequent increase in weight of the rotating parts, the importance of satisfactory thrust bearings cannot be exaggerated and a great deal of progress has been made in recent years.

The General Electric Company, Schenectady, N.Y., have developed a spring-supported thrust bearing in an effort to overcome certain difficulties experienced in the operation of thrust bearings on this character of service. The main features of the spring supported thrust bearing is that it automatically adjusts itself to unequal loading due to inaccurcies in workmanship or in alignment. A distinctive feature of this bearing is that it will automatically adjust itself while in operation if there is a loss of alignment due to settling of the foundation or to other causes.

The bearing is not affected by wobbling of the shaft. The rubbing surfaces are in a bath of oil and the quantity of oil circulated from an outside source depends on the losses and the cooling conditions. Water cooling coils may be installed in the bearing housing which will reduce the amount of oil and in certain sizes of bearings at low speed, no circulation of oil from a source outside the bearing housing is required.

The salient features of the G. E. spring-supported thrust bearing are:—

A thrust collar keyed to the shaft which transmits the weight of the revolving parts to the rotating ring of the bearings. This rotating ring has a smooth rubbing surface and is so designed that a rapid circulation of oil is maintained.

There is also a stationary ring, the upper surface of which is the stationary rubbing surface of the bearing. This ring rests on springs and to insure flexibility it is made thin and has a radical saw cut through one side.

Sufficient springs are provided so that the stress is only about one half that usually used and the deflection under load is about 0.1 in.

Cooling coils are used to carry off a part of all the heat generated between the rubbing surfaces of the bearing. Centre pins hold the springs in position. An oil tube is provided which forms the inside annular wall of the oil chamber and is welded to its supporting ring. Vowel pins keep the stationary ring from revolving.

G. E. Bearings at Cedars

Two of these bearings have recently been installed in the Cedars Rapids plant of the Montreal Light, Heat & Power Consld., in connection with the last two 10,800 h.p. units, and have now been in operation for some months and have given entire satisfaction.

These bearings are designed to sustain a load of 550,000 pounds during continuous operation of the generating units at a normal speed of 55.6 r.p.m. A good grade of lubricating oil well filtered and free from water or entrained air and at a temperature not greater than 43 deg. C. maintained at a level above the sliding surfaces is used and under these conditions bearings can carry 600,000 lbs. without injury.

The cooling coils are placed within the bearing housing beneath the surface of the oil and are of such length, number and size as will keep the temperature of the oil within the bearing housing under 45 deg. C. when supplied with water at 25 deg. C. under all conditions of normal operation. The bearings are capable of operating at a maximum runaway speed of the unit, not exceeding 111.2 revolutions per minute of the shaft, for the space of one hour, and the temperature of the oil not exceeding 55 deg. C. The bearings are also capable of starting from rest and stopping as often as may be required by service conditions.

Bearings are designed to suffer no injury due to interruptions of water circulation for space of one-half hour under otherwise normal conditions or for a space of 20 min. not exceeding 50% above normal speed.

The general construction of these bearings is such as will allow the bearing in all its parts to be removed from the bearing housing without disturbing the generator or waterwheel except by supporting the turbine shaft and generator by independent means provided, and removing the thrust block keyed to the top of the shaft.

These bearings are the first ones of this size to be equipped with water cooling coils for circulation of cooling water instead of using oil circulation.

Kingsbury Bearings at Queenston

The Kingsbury thrust bearing has already been described to a great extent in many engineering periodicals and shall not again be treated in this report. It may be of interest, however, that this type of bearing has been adopted by the Hydro-Electric Power Commission of Ontario for the Westinghouse generators on the Chippawa-Queenston development. They are designed to carry a load of 900,000 lbs. at 187½ r.p.m.

Governors

No radical departure from standard designs of governers, mechanical or hydraulic, have taken place recently. The tendency has been in the past to specify quick acting governors in order to maintain a constant voltage. This tendency may lead to serious troubles, particularly where the

turbines are connected to long penstocks which are not protected by relief valves or surge tanks.

Designers are aware of this danger and considerable attention is now paid to this problem.

Troubles encountered in governor systems, such as corrosion of pipe lines and governor parts, where water is used as operating fluid, are being met by the introduction of soluable oil barium hydrate and potasium bichromate into the operating fluid.

There still seems to be a difference of opinion among designers as to the advisability of using individual governor systems or having all governors receive the operating fluid from a central pumping system. The latter system is, as a rule, the cheapest and when the necessary care is taken laying out pumps, pipe lines, etc., very satisfactory from an operating point of view.

A noticeable improvement has taken place in recent designs of water turbines with regard to accessibility, thorough lubrication and easy cleaning of turbine parts. One of the important features of the single runner vertical unit is the easy removal of gate mechanism for inspection, as well as the easy adjustment of guide vanes.

SCREEN WHEEL FOR REMOVAL OF ALGAE IN IRRIGATION CANAL*

By E. Court Eaton
Superintendent Lindsay-Strathmore Irrigation District; Formerly Assistant Irrigation Engineer, C.P.R.

A GOOD deal of trouble was experienced by the Lindsay-Strathmore Irrigation District of Lindsay, Cal., during the season of 1918 with algae or "moss" in an open lined canal. To prevent the particles of this growth from entering the distributing pipes of the system, removable screens were first placed in the canal, and these were taken out and washed with a hose as required. It was found, however, that these screens required the continued presence of a man day and night, as they needed cleaning every 15 minutes. To do away with this expense, a revolving screen wheel was designed.

Driven by Paddle Wheel

The canal has a bottom width of 6.3 ft. and a total depth of 3.5 ft. A rotary drum, made of two circular sections of 3-in. lumber was made up and suitably braced. This was covered with a galvanized screen having a ¼-in. mesh; four vanes, or paddles, were placed inside this, it being the intention to have the wheel rotated by the velocity of the water in the canal.

It was soon found, however, that this had a tendency to roll the streamers of algae under the wheel, and thus allow a large percentage to pass the wheels. Accordingly, the paddles were removed and a separate paddle-wheel built in upstream, connected by a crossed belt of cable to the screen wheel, and by this means the wheel was rotated in a direction against the flow of the water. To assist in picking up the larger particles, six rows of nails were driven into the circumference, parallel with the axis.

Washed at Every Revolution

The screen wheel is supported by, and rotates on, a length of 4-in. wrought iron pipe as a shaft, and this pipe is perforated with a row of 3 16-in. holes. One end of this pipe is connected to one of the pressure mains from the pumps, thus washing off the collection of moss at each revolution, which is caught in a trough and run to waste.

The wheel has been successful, and would be improved if built up of steel, allowing smaller clearances between the bottom and sides of the canal and the rotating wheel. A good deal of water is necessary to clean the screens, this depending, of course, on the quantity of material to be removed.

*From "Engineering and Contracting," Chicago.

COST AND LIFE OF NEW YORK STATE HIGHWAY PAVEMENTS*

ON January 1st, 1918, we had in New York State 6,912 miles of pavement, of which 5,820 miles were non-permanent types and 1,092 miles permanent types, of the latter all but 129 miles being of brick or concrete.

Water-bound Macadam.—This pavement is best adapted to the needs of light traffic, but has no place on any through route. It costs to-day about $23,000 per mile for a 16-26-ft. pavement 9 in. thick (3-in. top on 6-in. sub-base). Low construction cost has been the greatest advantage. Its greatest disadvantage now is its high cost of maintenance, which in 1917 amounted to $970 per mile. The average life of this type of pavement is seven years for a traffic of under 1,000 tons a day. Many waterbound roads have worn out in from one to three years when called upon to carry a heavier tonnage.

Bituminous Macadam Penetration Method.—This type is also adapted to light traffic generally, and is advantageous in many localities where the only stone available is non-binding. Among its disadvantages is its tendency to creep under traffic. It is slippery when wet; has a fairly high cost of maintenance—$412 per mile during 1917; and a construction cost of $28,500 per mile for a 16-26-ft. pavement 9 in. thick (3-in. top course and 6-in. sub-base bottom course). The average life of this type is two years more than that for waterbound macadam under similar traffic conditions.

The determination given for average life of the above types was made in 1917. The much heavier traffic tonnage of to-day would shorten it considerably.

Concrete.—Has the disadvantage of a glare. It has the advantage of low first cost, $31,200 per mile to-day for a 16-26-ft. pavement 6 in. average thickness. The maintenance on it in 1917 was $112 per mile. Its average life so far can only be estimated, but, judging from the condition of 5 to 9-year-old pavements of this type with which I am familiar, we can say at least 15 years.

Brick Pavements, Semi-monolithic.—This type differs from the original brick pavement in that there is no sand cushion, but the bricks are laid in a cement sand bed and grouted with cement grout to form an integral part of the pavement. This type has the advantage of developing beam strength as in concrete pavement, and eliminates the shifting of and depressions in the brick. Its cost under present conditions would be about $50,600 per mile for a 3-in. brick on a 4-in. concrete foundation. I have no maintenance figures for this type, as we have been building it only a little over a year.

Brick Pavements, Monolithic Type.—It differs from the semi-monolithic type in that the brick are set in a green concrete and grouted with a cement grout, forming an integral part of the pavement. This type develops the full beam strength, and has even greater advantages, so far as strength is concerned, than the semi-monolithic type. It is more difficult, however, to get as smooth a surface as with the semi-monolithic type.

Asphaltic Concrete.—In order to insure a nearly smooth pavement, a smooth concrete foundation should be provided. These pavements have the disadvantage of pushing under traffic from future consolidation if the aggregate is not properly sized and proportioned, or carries too much bituminous material. However, if too little bituminous material is used, the pavement becomes dry and soon disintegrates. The ideal mix is one in which the motor oil dropped from cars renews the volatile oils lost. These pavements cost about $40,000 per mile, depending upon the type, with a 2-in. top and a 5-in. concrete foundation. Their maintenance cost in 1917 was $245 per mile.

There are many patent types of pavement which come under the classification of permanent types, and which are good.

*From a paper presented before the New York Chapter of the American Society of Civil Engineers by H. E. Breed, formerly Deputy Highway Commissioner of New York State.

CANADA'S CANAL SYSTEM*

By W. A. Bowden
Chief Engineer, Department of Railways and Canals

THE through water route between Montreal, at the head of ocean navigation, and Fort William and Port Arthur, on the west shore of Lake Superior, comprises 74 miles of canal, with 48 locks and 1,155 miles of river and lake waters, or a total of 1,229 miles.

The minimum depth of water on this route is 14 feet. From Montreal to Duluth, on the south-west end of Lake Superior, the total distance is 1,354 miles, and to Chicago 1,286 miles.

Connection is made with the Canadian Pacific Railway from points west and south at Fort William and Port Arthur, six miles apart. From Fort William connection with the main transcontinental line of the Canadian Government Railways is made by the branch line originally constructed by the Grand Trunk Pacific Railway, but now leased to and operated by the Canadian Government Railways.

On this through route the approaches to the canals and the channels of the intermediate river reaches are well defined, and are lighted with gas buoys under the control of the Department of Marine and Fisheries, admitting of safe navigation in the hands of competent pilots both by day and by night. The Lachine, Soulanges, Cornwall, Welland, and Sault Ste. Marie canals are lighted throughout by electricity and electrically operated. The Farran's Point canal is lighted by acetylene gas.

Of the minor systems, the Murray, Trent, Rideau, and Ottawa River canals may be considered geographically as branches of the through east and west route. In operation, however, these canals serve a distinct traffic of more local nature. Isolated from the systems just mentioned, the navigation of the Richelieu River, from its junction with the St. Lawrence at Sorel to Lake Champlain, is effected by means of the St. Ours Lock and the Chambly Canal; while in the extreme east the St. Peter's Canal provides communication between the Bras d'Or Lakes of Cape Breton Island and the Atlantic Ocean.

*From the annual report of the Department of Railways and Canals.

SUPER-POWER PLANTS**

By L. G. Denis
Hydro-Electric Engineer, Commission of Conservation

THE recent decision to proceed with the super-power station scheme for electric supply in Great Britain, calls to our notice what should be done along these lines on a more modest scale in certain portions of Canada.

The British plan to improve the supply of electricity throughout Britain contemplates the replacement of the numerous small stations now in operation by fewer but much larger stations supplying extensive districts through high-tension transmission works. There will be a gain both in economy and fuel conservation, and, in many cases, the quality of service will be much improved. This national electric supply operates under the supervision of five commissioners appointed by the Board of Trade; these, in turn, appoint district boards, which include representatives of electric undertakings, of large consumers and of labor.

Lancashire is to be one of the first areas dealt with, the county being divided into three districts. Some of the smaller stations will probably be shut down immediately, the energy transmitted from larger existing stations being substituted. Following the building of the new super-power plants, the commissioners will eliminate the remaining small stations and also the moderate-sized plants.

A similar situation, however, does not occur in Canada, as by far the larger portion of the capacity of our hydro-electric stations is to be found in what may be called "super-power" stations; many of them are also interconnected to allow more efficient operation.

There is, however, a portion of Canada where the absence of water power makes it necessary to supply power from steam or other fuel agencies. This area, which comprises southern Saskatchewan and adjacent portions of Manitoba and Alberta, is becoming of much importance through its rapid agricultural expansion, and its future needs should be anticipated so far as possible.

As pointed out in a report on "Electric Generation and Distribution in Canada," recently pubilshed by the Commission of Conservation, adequate supply of electric energy in this section is confined to a few large centres. The smaller municipalities have installed small electric plants, which are usually very expensive to operate and only give a night service. The rates which have consequently to be charged and the limited service prevent the full benefit which should otherwise be enjoyed from the various uses of electric energy. All these small plants through concerted action could be replaced by a few large and more efficient ones, each supplying a fairly extensive district by means of electric transmission lines. The cost of production would be reduced to about one-third and a better service supplied.

The example given in the above-mentioned report illustrates the possibilities in the Estevan district. A central power plant at Estevan would supply transmission lines radiating in various directions, covering a total length of 150 miles. The estimated demand, based on the requirements of the near future, shows a total of some 600 h.p. outside of Estevan. As the lines would only carry a light load, they could be built cheaply with light conductors and at a cost possibly not exceeding $2,500 per mile. If we allow a load factor of 40 per cent., the cost of transmission would average 2½ cents per k.w.h. The cost of production in the central plant would be from 2½ cents to 3 cents per k.w.h., so that the electricity could be delivered for an average of from 5 cents to 5½ cents per k.w.h. at the various small centres supplied. With a small plant, the present cost runs as high as from 15 cents to 19 cents per k.w.h. Numerous other districts, if treated in the same way, would probably show advantageous results.

**From "Conservation," the official bulletin of the Commission of Conservation, Ottawa.

BALDWIN'S CANADIAN STEEL CORPORATION

ANNOUNCEMENT is made that the British Forgings plant at Toronto, which was recently bought by Baldwin's, Ltd., of Swansea, Wales, will be operated as Baldwin's Canadian Steel Corporation, Ltd. The new firm will be capitalized at $10,000,000, it is said, and will employ 2,300 men within a year.

E. L. Cousins, chief engineer of the Toronto Harbor Commission, who negotiated with the company on behalf of the city and the harbor commission, states that A. M. Russel, of Hugh Russel & Sons, Ltd., Montreal, was largely instrumental in persuading Baldwin's to establish a plant in Canada. Mr. Russel went to Wales for the purpose of interesting his principals, with the result that J. C. Davies, managing director of Baldwin's, Ltd., came to Canada, accompanied by D. E. Roberts, consulting engineer of the company, and the deal was consummated soon afterwards. Mr. Russel will be president of the new Canadian corporation.

Within a few months the new firm will begin the manufacture of tin plates, black sheet and galvanized sheet. The British Forgings plant, located in the Toronto Harbor Commission's eastern harbour terminal, is 127 acres in extent, with 1,600 lineal feet of 24-ft. dockage. The new company also holds an option on 79 acres of additional land. A detailed description of the British Forgings plant was published in the March 27th, 1919, issue of *The Canadian Engineer*.

DRAFTSMEN'S ASSOCIATION ORGANIZED

FOLLOWING a series of meetings attended by a number of Toronto draftsmen, an association was recently organized under the name of the Draftsmen's Association. The address of the association is given as P.O. Box 453, Toronto, but the letterhead does not state the names of the officers of the society. A circular letter, also anonymous, has been mailed to draftsmen throughout Canada. This circular, which states that it was drafted by the association and approved by the executive committee, is as follows:—

"Following a series of meetings attended by a great number of draftsmen of all branches, the above association was duly formed, and the officials elected by secret ballot on the date set above. What were the salient reasons that prompted the draftsmen of the different professions or branches connected with the arts and science of building, construction, engineering and marine to become the pioneers of such a movement?

"1.—To promote more professional etiqutte of the various branches of arts and science similar to that of the physician, lawyer, etc.

"2.—To ensure that all work be carried out by men of specific qualifications.

"3.—That the branches of arts and science shall know each other closer in relation to their work and eliminate professional jealousy.

"4.—That by means of lectures and classes to be given by advanced members of the association, a broader knowledge be imparted to the younger element of all branches.

"5.—To act habitually through the associations of architects, engineers and draftsmen and their chapters; in other words, to act as a compact, professional body, and not as individuals.

"6.—To convince the employers of the different branches that the maintenance of ethical standards is the only right road to business success.

"7.—To make the employers believe in us because we believe in ourselves.

"8.—To promote such interest and participation in public and quasi-public affairs that will show the draftsmen to be men of general ability and civic pride, and not merely self-interested individuals.

"9.—To create a more equable relation between employers and employees.

"10.—That the employers who purchase the brains of the different services financially realize the value thereof.

"11.—Last, and not least, that by inspiration and thoroughness in the training of the junior draftsmen, this association aspires to do what the societies of architects and engineers have failed to do, namely, a more sound training in every branch of the arts and science, and ensure better recognition of the draftsman as a co-ordinate to the architect or engineer."

The explosion in the grain elevator at Port Colborne, Ont., was caused through the ignition of wheat dust, states the tentative report of the commission of engineers appointed by the Dominion government to investigate the accident. It is thought that the "leg" used for loading the boats jammed, causing excessive friction between pulley and belt. When the "leg" fell, raising a cloud of dust, the latter was ignited from the heat generated by the pulley.

Announcement was made in last week's issue that Jones & Attwood, Ltd., of Stourbridge, Eng., who are the owners of the patents on the activated sludge method of sewage disposal, were transferring that department of their business to a newly-formed firm, Activated Sludge, Ltd., of Stourbridge. Later reports from England state that while the new company has been registered, final arrangements have not yet been completed, and in the meantime all activated sludge business is being handled as in the past by Jones & Attwood, Ltd.

THE ORGANIZATION OF EFFICIENT CONCRETE ROAD CONSTRUCTION GANGS*

By Halbert P. Gillette

THIS question is often asked of the man who has made an enviable financial record: "What is the secret of your success?" If he is not a man given to analyzing his methods, he is apt to reply with some generalization that is too broad to be serviceable to others, such as "Hard work is the secret," or "Strict honesty," or "Attention to details," and the like.

The fact is that there is no single "secret" of success, whether it be winning battles or building roads. Success is usually a simple result, but it is never attained by a single "open sesame." It is the outcome of the judicious application of many separate factors. So, in discussing how to organize construction gangs with which to build roads economically, we must dismiss at once the idea that there is any one way that is invariably successful in accomplishing the desired minimum cost.

"Tricks of the Trade"

On the other hand, although different organizations are needed for different conditions, there are a few general principles of organization applicable under any condition; and there are many subsidiary principles of organization applicable under more specific conditions. In addition to such principles, there is an almost limitless number of "tricks of the trade" that can be profitably applied only under very specific conditions.

To illustrate, it is a good general rule of organization that each construction gang should be composed of men of the same nationality. This broad rule may be broadened to read: Other factors being equal, the best construction gang is one composed of individuals having similar temperament and habits. Experience has taught us that this is a sound rule of very broad application. It holds as true of sewer work as of road work, of military units as of a squad of religious revivalists.

There are, however, "secrets" of organization success that are of somewhat narrower application. Thus it is a good rule to make one of a gang of shovelers the leader or pace maker, that is, a sort of "working foreman." Such a man should be more ambitious than the rest, and close mouthed enough not to state his weekly bonus to his fellows. If paid a bonus of $5 to $10 a week above the average wage, a good "working foreman" will set a pace that will decidedly increase the output of a shoveling gang. This principal of employing "working foremen" is one that was formerly more commonly applied than at present. It has lost none of its efficacy.

"Spotting" and Regulating Loads

As an example of a minor "trick of the trade," or economic method of limited application, the following is offered. Let it be the duty of one man to "spot" every load of stone (or gravel) and sand, instructing the driver exactly where to dump it. This man may also have other functions to perform, such as setting the side-boards or "rules," trimming subgrade, or what not. But even if he were to do nothing else than place the aggregates properly, he would save more than his wages. It is not uncommon to see piles of stone or gravel shoveled off the roadbed onto the shoulders, because loads of aggregate were dumped too close together. It is equally common to see loads too far apart, resulting in long hauls for wheel-barrows and the subsequent bringing in of extra wagon loads of materials under adverse hauling conditions.

Closely allied to this "trick" of having a man "spot" each load, is having a man regulate the size of loads at the point of loading. The size of wagon or truck loads may vary 5 to 10% unless it is some one's duty to watch the loading. Standard loading is highly desirable, as a little consideration will show. But by standard loading, I do not mean an unvarying size of load throughout an entire job. I mean a standard size for given hauling conditions. If the earth over which the load is hauled is hard, and if the grades

*From the "Concrete Highway Magazine."

are easy, the standard load should be large. Under more difficult hauling conditions, it should be smaller. But in every case, the standard load for given conditions should be adhered to rigorously. This can be accomplished only by making it the special duty of some one to watch the loading of wagons or trucks.

Reviewing the three examples just given, we have (1) the broad principle of selecting similar individuals for each gang; (2) the narrower principle of having a "working foreman" for shoveling gangs; and (3) the still narrower construction methods of "spotting wagons" and of "standard sizing of loads."

In this connection it may be well to point out that men of college education are apt to be unduly impressed by what are called "general principles." Let a "law of nature" be announced and most college men are prepared to kowtow; but let a "trick of the trade" or a "construction method" be announced and they may not deign to lift an eyebrow. I am convinced that this false attitude toward the humble "tricks of the trade" accounts largely for the failure of many a college engineer to make a good superintendent of construction. However, engineering colleges are rapidly improving and fewer students are being graduated under the false impression that a knowledge of "tricks of the trade" is less important than a knowledge of broad principles.

The only difference between the worth of a broad principle and of a special economic method, or "trick," lies in the number of cases to which each is applicable. Hence it may happen that it is worth more to a road-builder to know that it pays to "spot" wagon loads than to know Newton's laws of gravitation.

A manager of concrete road gangs should be acquainted not only with the general principles of scientific management but with a great many specific methods of transporting, mixing, placing and surfacing concrete. The larger his store of knowledge of methods, the more likely it is that he will select an economic combination of methods for any given job. Hence the importance of storing the mind with published methods and hints relating to road work. This seems perfectly self-evident, yet it is a fact that the majority of construction managers add very little to their knowledge except through personal observation.

Contractors Must Study Work

It also seems self-evident that gangs should be so organized that all the workmen will be kept uniformly busy. Yet it is very common to see a large percentage of time wasted because of poor co-ordination. This is attributable to the fact that the manager does not know what constitutes a fair day's work for a man engaged in each of the separate processes or duties. Thus, if the manager does not know how many cubic yards of sand a workman should load per hour into barrows, and how many cubic yards he should be able to wheel a distance of 100 ft. per hour, he cannot accurately assign the right number of sand loaders and wheelers to a mixer having a given hourly capacity of concrete.

For the most accurate studies of gang organization, it may be desirable to time every single process and every minute delay, using a stop watch for the purpose. Such great refinement is not ordinarily needed on construction work. But it is desirable to know the average hourly output of good workmen on each class of work under any given conditions. To do this, any given class of work should be analyzed into two general parts, namely (1) the parts that do not vary materially on different jobs, and (2) the parts that vary on different jobs. Thus, in hauling sand with wagons, the team time lost in loading and dumping each load is quite uniform, but the time spent in hauling depends on the length of the haul. Hence the time can be expressed as a constant number of minutes (say 10 minutes) per load plus a minute per 100 ft. of distance between the loading and the dumping points. With such a rule in his head, a manager is able to assign the proper number of teams to the hauling of sand. Similarly for wheelbarrow work, or for any other kind of hauling.

Having thus scientifically selected the proper number of men and teams for each duty, the manager should watch them carefully to ascertain whether there is any "soldiering" or unnecessarily lost time, either because too many or too few men have been assigned to a given task. If too many men have been assigned, say, to loading sand, the manager can usually ascertain the fact by watching them for half an hour. If too few men have been assigned to sand handling, the other men will be delayed, and this can be readily ascertained by observing the other men. So an experienced manager need not necessarily know the average time required to perform each operation, but, by a "cut and try" method, he can distribute his men with considerable accuracy. Nevertheless, even an experienced manager will effect a better organization of his forces if he knows what to expect of a man on each kind of work under given conditions.

I have found, as have other road builders, that the timing of each separate operation and each cause of "lost time" is one of the most effective means of improving the organization of men. Lost time is the greatest source of lost profits on road work. On most concrete road jobs the average daily progress of a mixer gang for a month is about half what it is during a day when everything runs smoothly. Extra parts and duplicate machines would do away with most of this lost time. But managers usually do not keep a detail record of all lost time and the causes. Hence they usually fail to realize the true economy of having spare parts, spare pumps, duplicate pipe lines, etc. For the same reason, they usually fail to realize that it pays to have spare men—men able to fill a gap or ready to attend to a breakdown or to shift a plant with expedition. A small emergency gang of "Jacks of all trades" will usually earn their wages many times over by reducing delays from breakdowns, plant shifting, short-handed crews, etc.

Keep a Note-Book

The average workman likes to do only one class of work. If his job is to finish a concrete surface, he resents being required to load a wheelbarrow. This is easy to understand where a skilled man is required to do unskilled work. Why a common laborer should resent being shifted from one class of unskilled work to another class is not so clear, but it is a fact. A wheelbarrow man dislikes turning his hand to pick and shovel work, for example. But there are a few men who seem to enjoy frequent changes, and will gladly do anything from grubbing roots to shoeing a horse, provided they are not kept at one thing very long. This is the type of man for an emergency gang. Every large road job should have such a gang.

In a brief article on a big subject it is impracticable to do more than throw out a few suggestions. Of the few here offered, there is one, however, that will prove profitable to every manager of road gangs. It is this: Keep a note book in which you enter a memorandum of every "trick of the trade" that you see, hear, or read. Number each of these "hints" serially. Read them over at intervals. You will ultimately have nearly every one of several hundred "hints" committed to memory. And as your stock of memorized "hints" grows, you will find it progressively easier to remember new "hints." Most men make the mistake of regarding the brain as a store house of limited capacity for memorized facts. Its capacity is practically limitless; and, curiously enough, the greater the number of facts of a given class that a man memorizes, the stronger does his memory grow for facts of that class. College trained engineers are particularly prone to avoid memorizing details. They argue that they need remember only general principles and that they can look up published details when necessary. In practice, however, they seldom look up published details in a thorough-going manner, partly because they haven't the sources of reference at hand, and partly because published indexes are wholly unsatisfactory for the purpose of finding such details.

In reading biographies and sketches of famous men, it is worth noting that such men are so frequently credited with having an astonishing command of memorized data relating to their specialty. James J. Hill, "the empire builder," had a memory for details of railway operating and construction costs that was amazing. He was a genius as an organizer and promoter. Certainly, his feats of memory were not merely incidental to his success, but, in large measure, accounted for it. If we cannot all be prodigies like Jim Hill, at least we can profit by using his methods.

CONSULTING ENGINEERING ETHICS

IS it ethical for consulting engineers to quote less than 5% (of the cost of the work) for plans, specifications and supervision of erection of buildings, bridges, power plants or any other engineering undertakings? and what, if anything, should be supplied for that amount, other than the plans, specifications and personal supervision?

These questions are being actively debated among the consulting engineers of Toronto, due to recent keen competition for appointment in connection with an important bridge. One firm offered to do the work for 4%; all the other engineers asked 5%, but after their letters had been read in council meeting, and it was published that an offer of 4% had been received, one of the engineers who had bid 5%, reduced his figure to 4%, and subsequently one other 4% offer was received from a firm that had not previously tendered its services in formal manner. The work was awarded to the engineer who cut his price from 5% to 4% after he saw that another engineer had bid 4%.

Which of these two engineers, if either of them, was guilty of unethical conduct?

The man whose original bid was 4% states that 4% is his regular fee for certain classes of work, and that no engineer should have altered his price after it had been tendered. He says that he considered his services on such work worth 4%; and that if another engineer considered his own services worth 5%, he should not have entered into a price-cutting competition, but should have allowed the owners of the proposed bridge to determine whether the one man's services would be worth more than the other's services.

This man, therefore, thinks that the "cutting" from 5% to 4% was unethical, but that he was fully justified in quoting 4%. On the other hand, the engineer who "cut" is of the opinion that he was justified in so doing in order to meet unethical competition; in other words, that it was not ethical for any engineer or engineering firm to quote less than 5% at any time for plans, specifications and supervision.

Webster defines ethics, as applied to professions, as follows: "Any body of principles or rules concerning moral obligation, whether true or false, that is intended to regulate practise in any particular sphere of activity."

Are there any "principles or rules" that were violated by either of these engineers? The code of ethics of the Engineering Institute of Canada contains no reference to fees or price-cutting. The code of ethics of the American Society of Civil Engineers says: "It shall be considered unprofessional and inconsistent with honorable and dignified bearing for any member . . . to compete with another engineer for employment on the basis of professional charges, by reducing his usual charges and in this manner attempting to underbid after being informed of the charges named by another." The code of ethics of the American Institute of Consulting Engineers contains a clause almost identical to that in the A.S.C.E. code.

Obviously, however, there was no intention of *underbidding* on the part of the engineer who cut his price, but merely of *meeting* the other man's lower bid. The clause quoted above does not seem to prohibit such a reduction. It would, however, prohibit a bid of 4% if a firm's regular fee were 5% and if the reduction were made knowing that another engineer had quoted 5%. In this case, the engineer whose original bid was 4% states that 4% is his regular price on work of that amount and character. Moreover, his bid was the first one received by the owners and antedated all others by at least four days.

The only civil or consulting engineering society that has adopted a schedule of fees is the American Institute of Consulting Engineers, which stipulates 5% or more for preliminary examinations, surveys, plans and specifications, final working drawings, and consultation and general advice during construction. This is much less than the two Canadian engineers above referred to, offered to do for the same or smaller percentage. The firm that originally bid 4% offered "to place a resident engineer experienced in concrete bridge work on the job and do all necessary testing of materials entering into the construction of the bridge. In addition to the above, this fee would include the regular supervision of the work by members of this firm and preparation of monthly estimates, etc."

The engineer who reduced his bid from 5% to 4%, and who was appointed, agreed to "supervise, either by himself or by skillful, qualified persons that he may substitute, the erection and construction of the said bridge by the contractors and all work that may be incidental and necessary to properly carry out the work required for the completion, construction and erection of the said bridge . . . and that he will make proper and sufficient plans, specifications and estimates and inspections."

Toronto consulting engineers are therefore debating the advisability of adoption, by the Engineering Institute of Canada, of a schedule of minimum fees, but the majority are opposed to such action until after the American Society of Civil Engineers has adopted a similar schedule, fearing that American engineers may quote lower rates and take much work away from the Canadian engineers. Should the Engineering Institute be successful obtaining legislation closing the profession in Canada, the Canadian engineers could successfully establish a schedule regardless of what American engineers might charge; because then, in order to do work in Canada, the American engineers would have to belong to the Engineering Institute and consequently would be amenable to its regulations regarding fees in Canada.

There are times when an engineer might desire for personal reasons to become associated with some big job almost regardless of remuneration. To be forced to charge as much as men who were not actuated by the same motives, but who were bidding on the work as a purely commercial proposition, might then seem to him to be a hardship and a violation of his personal liberty. But we have all learned during the past few years that one's purely personal rights

matter but little when they are in conflict with the welfare of society as a whole, and there is no doubt but that a minimum fee, strictly observed, would certainly be beneficial to engineering as a profession and to the entire community of engineers.

Another point upon which there has been discussion, is the interpretation of the words "usual charges" in the American Society's code. What determines "his usual charges?" Must he publish or announce a personal schedule of fees? If so, could he ever lower those fees? Suppose that two engineers are being considered for certain work. Both have published schedules calling for 5%. If one of them were to submit a tender of 4%, would he not be cutting with real intention of underbidding the other man, even though the other engineer had not yet quoted on that particular work?

Moreover, just what services should a consulting engineer perform for any fixed percentage that might be adopted? The American Institute of Consulting Engineers requires its members to charge at least 10% when, in addition to preparing all the plans and specifications, they are called upon to test materials, to inspect the work and to be responsible for the organization, management and completion of the construction.

DEATH OF ANDREW CARNEGIE

ANDREW CARNEGIE'S death, August 11th, at Lenox, Mass., brought to a close a career which greatly advanced all the engineering arts and sciences. By the introduction into the United States of the Bessemer process for the production of steel, and by the establishment and development of steel plants which became the greatest in the world, he made available for engineers the most useful modern material for engineering construction.

In the successful conduct of many industrial enterprises, he amassed great wealth, the possession of which he came to regard with deep seriousness as a public trusteeship. While yet in full possession of his faculties, he devoted himself to the distribution of large portions of his fortune to projects for the benefit of mankind.

Mr. Carnegie distributed his wealth not only in many directions, but also with the exercise of great wisdom based on careful investigation. His munificence provided large funds for the building of homes for engineering societies, a number of which had elected him as an honorary member.

PRODUCTION OF COAL IN CANADA

(Continued from page 238)

ports, but in 1918 the imports of coal increased without precedent, while domestic coal outputs are declining with no immediate prospect of manifesting an opposite tendency.

It appears equally desirable and feasible that Canadian coal producers should strive to lessen the recently developed inequality in the ratio of imported coal to coal mined in Canada. Admitted that a certain tonnage of anthracite coal is probably required for domestic use because of its greater cleanliness, there is yet a large market for bituminous coal in Canada that is being filled to-day from United States sources.

Apart from the fact that raw materials obtained from outside sources provide employment in that outside source and not in the country where they are used—at least not in the same proportion—there is the further consideration that we are to-day paying for imports with a depreciated currency.

In a lecture recently delivered to the staff of Barclay's Bank, in London, Prof. Nicholson says with reference to conditions in Great Britain:—

"We are suffering in the first place from over-importation. During the war a great part of this over-importation was of the greatest national benefit. The imports from America were necessary for the conduct of the war. But an increasing part of the aggregate money value of these imports was due to the inflation of the currency and the associated rise in prices. This part was not a blessing—quite the contrary."

While a wholesale application of Prof. Nicholson's statement is not justified, yet in relation to the coal consumption of Canada, the statement is one of fitting exactitude. In brief, we are importing altogether too much coal and we are purchasing it at an increasing disadvantage.

PERSONALS

D. A. R. McCANNELL, who was recently appointed city engineer of Regina, Sask., was born in 1890, in Bruce County, Ont. His parents moved to Regina in 1893, his father being one of the first settlers who located there in 1882, before the municipality of Regina was formed. Mr. McCannell acquired his public and high school education in Regina, subsequently graduating in civil engineering at Queen's University. Commencing practice as a rodman with the engineering staff of the city of Regina in the summer of 1911, he was engaged on pavement construction until 1915, when he was appointed assistant to the city engineer. This position he held until 1917, when he became acting city engineer, and recently the city council decided to drop the word "acting" from his title.

M. L. CANTELL, of St. Boniface, Man., who is on the engineering staff of the Manitoba government, has been elected a member of the Royal Society of London, Eng.

J. LEBLANC has been appointed by the city commissioners of Montreal, as supervising engineer in charge of that city's contract work, in place of W. Matheson, resigned.

GORDON KRIBS, assistant engineer on the staff of the Hydro-Electric Power Commission of Ontario, has resigned in order to accept a position as manager of the Hespeler Manufacturing Co., Hespeler, Ont. Mr. Kribs is a graduate of the University of Toronto, Faculty of Applied Science and Engineering, class of 1905. For several years Mr. Kribs was in Texas as engineer for the Texas Power & Light Co.

ARTHUR H. BLANCHARD, consulting highway engineer, New York City, who is well known among Canadian engineers, has been appointed professor of highway engineering at the University of Michigan, Ann Harbor, Mich., the appointment to be effective commencing September 15th. This is a new chair at the University of Michigan, having been created at the last meeting of the board of regents. In addition to his consulting practice, Prof. Blanchard has been associated for some years past with the highway engineering department of Columbia University. He has given numerous lectures to Canadian audiences on various phases of highway work. Prof. Blanchard is best known as the chief editor of the "American Highway Engineer's Handbook." He is the author also of several other well-known books on highway engineering.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

ADDITIONAL TENDERS PENDING

Further information may be had from the issues of *The Canadian Engineer*, to which reference is made.

BRIDGES, ROADS AND STREETS

Amherstburg, Ont.—Tenders will be received by the town council, until 8 p.m., August 25th, for a concrete pavement on Murray and Dalhousie Sts. W. A. McCormick, town clerk, Box 161, Amherstburg.

Amherstburg, Ont.—Tenders will be received by W. A. McCormick, town clerk, Box 161, Amherstburg, up to 8 o'clock p.m., Monday, August 25th, 1919, for a concrete pavement on Murray and Dalhouise Sts., according to plans and specifications which may be seen in the office of the town clerk.

Brantford, Ont.—Construction has commenced on the Brantford-Hamilton highway. Curves are being eliminated as far as possible and the road widened. Pavement to be laid, bitumin. Estimated expenditure for 1919, $100,000.

Brantford, Ont.—Contract has been awarded by the city council, for construction of asphalt concrete pavements on Chatham and George St., $2.00 per sq. yd., and on Dufferin Ave., $1.85 per sq. yd. Contractor, Standard Paving Co., Ottawa.

Brantford, Ont.—Scarfe and Co., contemplates extensions to their varnish factory.

Brantford, Ont.—The highway between Hamilton and Brantford will be constructed on macadam specifications similar to such roads in England, etc. Hon. F. G. Macdairmid, minister of public works, Ontario.

Brockville, Ont.—The town council contemplate paving Pearl St., estimate of cost, $44,092, and Pine St., estimate of cost, $12,094. W. A. Lewis, mayor.

Cobourg, Ont.—Contract awarded to M. Jex and Co. for the construction of a new curling rink for the Waverly Curling Club. Work has commenced.

Creston, B.C.—Contract has been awarded by the department of public works to G. Hunt, Kitchener, B.C., for construction of 1.5 miles of new road between Goatfell and Creston. Wm. Ramsay, district engineer.

Edmonton, Alta.—Sidewalks planned include both sides of 107th St., from Jasper Ave. to 100th Ave. Cinder walks to be built on the south side, 2 mls., west end, 2 mls., east end, 2 mls. Cost, $7,000. City engineer Haddow.

Edmonton, Alta.—The city council will consider construction of a new concrete sidewalk on Grierson St. A. W. Haddow, city engineer.

Fort William, Ont.—City council will construct sidewalks on Vicker's and Harold Sts.

Fort William, Ont.—Tenders will be received until August 30th, by the municipality of Paipoonge, for construction of a timber bridge and a culvert. W. A. Dyke, clerk, 115 St. May St., Fort William.

Fort William, Ont.—Tenders will be received until noon, August 29th, by the city engineer, for construction of approximately 1,550 lin. ft. of curb and gutter, 4,300 sq. yds. asphalt, asphalt concrete, or bitulithic pavement on 6-in. concrete base. C. B. Symes, city engineer. (Official advertisement in this issue).

Galt, Ont.—The board of works will undertake temporary repairs to the Main St. bridge this fall. It is expected that a new single span bridge will be constructed in the spring.

Golden, B.C.—Tenders will be received until noon, August 25th, by the department of public works, Victoria, for construction of a bridge over the Blaeberry river. Plans, etc., at offices of assistant district engineer, Golden, B.C., and district engineer's office, Vancouver. A. E. Foreman, chief engineer, Victoria, B.C.

Guelph, Ont.—The International Malleable Iron Co., will erect a new reinforced concrete and brick factory extension. Estimated cost $33,000. W. A. Maloney, architect.

Halifax, N.S.—Tenders will be received until noon, August 27th, by the C.N. Ry., for construction of dock marginal and other paved and macadamized roads and streets at the Halifax Ocean Terminals. Plans, etc., at offices of chief engineer, Moncton, N.B.; superintending engineer, Halifax Ocean Terminals; division engineer, C.N. Ry. Tunnel Station, Montreal. F. P. Brady, general manager, Montreal, Que.

Hamilton, Ont.—An experimental pavement is being laid on MacNab St., between Main and Jackson Sts. If successful, similar pavements may be laid on steep grades near the mountain. E. R. Gray, city engineer.

Hamilton, Ont.—Bulk and separate tenders will be received by R. L. Foster, secretary of the board of education, up to 5 p.m., Monday, August 25th, for the erection of a 12-room school on Hunter St. W. Plans and specifications may be received at the office of F. W. Warren, architect, Bank of Hamilton Building.

Hamilton, Ont.—By-law has been passed authorizing completion of sidewalk on East 32nd St.

Hamilton, Ont.—Lord and Greenhood have purchased the Royal hotel and will construct an additional story.

Islington, Ont.—The Etobicoke township council will widen the roadway to 66 ft., from Weston to the border of Peel county, for which a strip of land has been purchased by the York county highways commission.

Kingston, Ont.—The board of works has sanctioned the street repairing. Additional expenditure, $3,000. Alderman Graham.

Kitchener, Ont.—Part of the plant of the Canadian Consolidated Felt Co. was completely destroyed recently by an explosion.

Kitchener, Ont.—Tenders addressed to J. I. Fletcher, Hannon R.R. 1, Ont., will be received up to August 28th, 1919, for work and materials required in the erection and completion of a soldiers' memorial hall for the board of trustees, Binbrook, Ont. Plans and specifications may be seen at the office of J. A. Armes, architect, 183 Bold St., Hamilton, Ont.

Kitchener, Ont.—The initial steps have been taken in the construction of a concrete roadbed on the main road leading from St. Jacobs to Elmira for a distance of three miles. It is expected that this stretch of roadway will form a portion of the provincial highway which has been designated from Elmira to Hamilton.

Londesboro, Ont.—Contract for material and construction of a memorial hall here has been let to Cockerline, Floody and Griffiths, Blyth, Ont.

Levis, Que.—The Levis county council passed a resolution requesting the government to open a vehicular roadway upon the Quebec bridge.

London, Ont.—The city council will receive a report from the works department on extensive repairs required to bridges at Ridout St., Chelsea Green, Dundas St. and Blackfriars. H. A. Brazier, city engineer.

Lundbreck, B.C.—Construction has commenced on the federal highway, between Lundbreck and the Crow's Nest Pass. Construction foreman, F. H. Robins.

Macgregor, Man.—Tenders will be received until noon, August 23rd, by the North Norfolk municipal council, for construction of three bridges,—E. Section 5-11-11 west, E. Section 18-12-12 west, E. Section 33-10-9 west. F. E. Lewin, secretary-treasurer, Macgregor, Man.

Moncton, N.B.—Tenders addressed to C. B. Brown, chief engineer, Canadian National Rys., Moncton, N.B., will be received up to 12 o'clock noon, Wednesday, August 27th, 1919, for the construction of docks, marginal and other paved and macadamized roads and streets at the above-mentioned location. Plans and specifications may be seen at the offices of the following: Chief engineer, eastern lines, Moncton, N.B.; superintendent engineer, Halifax ocean terminals, Halifax, N.S.; division engineer, C.N. tunnel station, Lagauchetiere St., Montreal, P.Q. Tenders for alternative propositions will be considerd if received from bona fide paving contractors, provided such alternative tenders are accompanied by complete specifications.

Montreal, Que.—It is said that the public works department, city hall, are preparing to repair the streets, on which over 20 gangs of men will be employed.

Montreal, Que.—Tenders will be received until 12 o'clock noon, August 28th, by the department of railways and canals, Ottawa, for repairs to roadway on the north embankment of the Soulanges canal. Plans, etc., at the offices of the chief engineer, Ottawa, and superintending engineer, New Birks building, Montreal. J. W. Pugsley, secretary.

Morrisburg, Ont.—Handley-Page, Ltd., has secured a Canadian charter and will probably construct factories, etc., with head offices at Morrisburg.

New Westminster, B.C.—Contract has been let to D. Philpot for the construction of the Whonnock Creek bridge at $1,590.

Oshawa, Ont.—Tenders will be received by the town council, until 5 p.m., August 28th, for construction of 17,000 sq. yds. concrete pavement and 10,000 lin. ft. concrete curb. W. G. Worden, town engineer. (Official advertisement in this issue).

Ottawa, Ont.—A commission, consisting of C. A. Magrath, Ottawa; J. P Mullarkey, Montreal, and R. Home Smith, Toronto, has been appointed to act with the minister of railways in an advisory capacity in carrying out the good roads policy.

Ottawa, Ont.—A conference will be held in Ottawa by the provincial highway commissioners to decide on the matter in which the federal grant of $20,000,000 for good roads will be decided.

Ottawa, Ont.—Tenders will be received until 3 p.m., August 26th, by the works department for construction of the following pavements: Booth St., from Somerset St. to the G.T. Ry.; St. Patrick St., from Sussex St. to MacKenzie Ave.; Murray St., from Cumberland St. to King Edward Ave.; Goulburn Ave., from Somerset St. to Osgoode. A. F. Macallum, commissioner.

Penticton, B.C.—The Kettle Valley Railway Co. has provisionally agreed to erect a warehouse for the United Seed Growers.

Regina, Sask.—A committee of the Regina Automobile Club will request the government to construct a concrete highway from Regina to Moose Jaw, 50 miles. Estimated cost, approximately $40,000 per mile.

Regina, Sask.—Contract awarded for paving Dewdney St. and spur track crossing with sheet asphalt, to the Crown Paving Co., Calgary, previously reported in this column page, amounted to $34,595.86, of which, $21,595.20 was for paving Dewdney St. Rejected tenders, Bitulithic Paving & Contracting Co., track crossings, $16,565.09, Dewdney St., $30,400.38. Crown Paving Co., asphaltic concrete, track crossings, $12,893.70, Dewdney St., $20,604.60. City engineer, track crossings, $10,480.58, Dewdney St., $22,268.00. D. A. R. McCannel, city engineer.

Ridgeway, Ont.—The construction of a concrete roadway through the village, for which contract was awarded, $22,000, has been vetoed by the deputy minister of the highway department on the grounds that inexpensive repairs

---

TOWNSHIP OF YORK

CONSTRUCTION OF WATER MAINS

Sealed tenders, plainly marked as to contents, will be received by the undersigned engineer for the Municipal Corporation of the Township of York, up to 12 o'clock **noon**, Saturday, September 6th, 1919, for the construction of 6-inch cast-iron water mains in the following streets in the Township of York:—

1. Amherst Ave., Jesmond Ave., Ashbury Ave., Roach Ave., Humewood Ave., about 5,214 ft.
2. Craydon Ave., Ray Ave., Rutherford Ave., Victoria Blvd., Eglinton Ave., Brownhill Ave., Barr Ave., Elora Ave., about 5,066 ft.
3. Cliff St., Bushey Ave., Jasper Ave., Langden Ave., Orla Ave., Chryessa Ave., Gray Ave., Outlook Ave., Humber Crest Blvd., about 6,139 ft.
4. Lauder Ave., about 3,200 ft.
5. Mitchell Ave., about 1,136 ft.
6. Northland Ave., Lapp St., Spears St., McCormack St., about 3,803 ft.
7. Northcliffe Blvd. North, Lavinia Ave., Runnymede Rd., Ostend Ave., about 3,043 ft.

Plans and specifications and all necessary information may be obtained at the office of the Engineer, Frank Barber, 40 Jarvis St., Toronto.

The lowest or any tender will not necessarily be accepted.

FRANK BARBER,
Engineer.

Toronto, August 18th, 1919. 331

to the present road would have been sufficient while so many other roads in the province were in worse condition.

Sandwich, Ont.—Tenders will be received by the town council until 8 p.m., August 25th, for construction of the following:—Silex walks, both sides of Indian Rd., from London to Victoria Sts.; on the s.w. side of the Huron line from London St. to the southerly end of lot 1, plan 54; both sides of Randolph Ave., Wyandotte St. to Craig St.; both sides Rankin Ave., north line of lots 488 and 489 to Craig St.; southside Wyandotte St., from the easterly town limits to California Ave.; both sides Brock St., Baby St. to Bloomfield Rd.; south side of St. Joseph St., Peter St., to Bloomfield Rd.; east side of Peter St., St. Joseph St., to St. Antoine St.; west side Baby St., Chippewa St., to St. Antoine St. Water mains on Randolph Ave., from Wyandotte St. to Craig; Rankin Ave., from north limits to lots 488 and 489 to Craig St.; Wyandotte St., from Randolph to Rankin; Indian Rd., from London to Victoria St.; Peter St., from Huron line to Pajot Lane, all with ¾-in. lead service pipes to lot lines. Engineers, McColl & Fletcher, Windsor. E. R. North, clerk, Sandwich.

Sandwich, Ont.—The council has decided to widen Sandwich St. at the corner of Detroit St., also to construct sidewalks on several streets, for which tenders are called.

Sarnia, Ont.—The proposed Roosevelt memorial road, which is being designed to connect Portland, Oregon, and Portland, Maine, will pass through Sarnia, London and Hamilton. John Bridge, Chamber of Commerce, London.

St John, N.B.—Contract awarded to Ring & Irons for a concrete sidewalk to be erected on Main St., Fairville, between North St. and Barnhill's Corner. Contract price, $2.38 per yard.

St. Adolphe, Man.—Tenders will be received by the municipal council until 11 a.m., September 2nd, for construction of three reinforced concrete culverts and two miles of roads. C. Gauthier, clerk.

St. Francois Xavier, Man.—Grading will soon be commenced on 12 miles of highway through the municipality. Estimated cost, $24,000.

St. Telesphore, Que.—Contracts have been awarded by the Levis Rd. Commission, to George Therrier, Levis, Que., for cement pavement at St. David de L'Auberiviere, and a steel bridge over the Scie River. Arthur Pigeon, secretary.

Stonewall, Man.—Tenders will be received until August 23rd, by the municipality of Rockwood, Man., for construction of a reinforced concrete bridge, 25 ft. span, N. 7-17-3 E., for double 3 ft. by 5 ft. culverts at N. 12-14-1 E., through 26-13-1 E. and N.E., 24-16-2 E. V. W. McFarlane, secretary-treasurer.

Stratford, Ont.—City Council intends to construct a number of concrete sidewalks. R. R. Long, city clerk.

Toronto, Ont.—A foot-bridge will probably be erected over the railway tracks and the Don River in Riverdale Park.

Toronto, Ont.—Contracts have been awarded by the city council for construction of roads as follows:—Elm St., Yonge to Chestnut St., $18,430, works department; Front St., York to Simcoe St., $15,073, works department; Grosvenor St., Yonge to Queen's Park, $19,533, works department; Silverthorne Ave., $28,062, Godson Contracting Co.; Silver Birch Ave., $15,734, Asphaltic Paving Co. R. C. Harris, commissioner of works.

Toronto, Ont.—It is expected that the construction of the new steel mills of Baldwin, Ltd., Swansea, Wales, will be under way in September or October. The location is the former British Forgings plant on Harbor Commission property.

Toronto, Ont.—Tenders will be received until noon, September 2nd, by the board of control for the following pavements: Asphalt—Davenport Rd., from E.S.L., Ford St. to Weston Rd.; Northcliffe Blvd., from St. Clair Ave. to north city limit. Bitulithic—Kennedy Ave., from Bloor St. to Colbeck St.; Skipper Ave., from Jones Ave. to Donlands Ave. Brick block—Pine Cres., from 128 ft. 4 in. west of W.S., McLean Ave., to 200 ft. west of Balsam Ave. Concrete—Cuthbert Cres., from Belsize Dr. to Manor Rd.; St. Clements Ave., from Yonge St. to Duplex Ave. Track allowance—Broadview Ave., from Queen St. to Danforth Ave. Grading—Morton Rd., from Oakcrest Ave. to Danforth Ave. T. L. Church, chairman.

Toronto, Ont.—The Bloor St.—Danforth Viaduct roadway will probably be completed by the end of August. R. C. Harris, works commissioner.

Toronto, Ont.—The Toronto Housing Co. has received a permit for the erection of 32 pairs of semi-detached brick veneer and stucco dwellings on Webb Ave., near Runnymede Rd. Estimated cost, $188,900.

Toronto, Ont.—Work will be commenced on the filling of the Gerrard St. hollow immediately after the closing of the Exhibition. R. C. Harris, works commissioner.

Trail, B.C.—The city council has decided to construct concrete sidewalks on Bay and Cedar Ave., and Spokane St. Estimated cost, $9,190. Wm. E. B. Monypenny, city clerk.

Vancouver, B.C.—The school board awarded the contract for building the new Kitsilano high school to Peter Tardiff and Co., for $17,911.25.

Vancouver, B.C.—An alternative route to the Hope-Princeton highway has been suggested by Gerald Kent, civil engineer, Vancouver. This proposed route would mean the construction of only 40 miles of new roadway situated between Whytecliffe and Squamish, along Howe Sound, and a few connecting links between Squamish and Lillooet.

Victoria, B.C.—The Princeton board of trade has requested the city council to endorse provincial highway construction through Princeton and Hope to Alberta, via the Crow's Nest Pass route.

Virden, Man.—Tenders will be received until 5 p.m., August 27th, by the municipal council, for construction of a reinforced concrete bridge over Gopher Creek, Seventh Ave., Virden. Wm. Whiteford, secretary-treasurer.

Waterloo, Ont.—The Waterloo county council is requesting co-operation from councils of other municipalities to connect with border counties by a concrete highway passing from Wentworth county line to Galt, Preston and Kitchener, and from Waterloo to St. Jacobs, Elmira and Flordale to the Wellington county line.

Welland, Ont.—The new concrete road being constructed by the department of railways and canals, between Port Colborne and Welland, is being widened from 9 ft. to 14 ft.

Windsor, Ont.—The high level bridge between Windsor and Detroit, Mich., proposed as an international war memorial (recently reported in this column page), would have a clearance of 120 ft., and a single span, length 2,500 ft. Dr. J. A. L. Waddell.

Winnipeg, Man.—The works committee has recommended establishment of a 32-ft. concrete safety island at Smith St. and Portage Ave. Estimated cost to equip the roads of the entire city with these islands, $8,400.

Winnipeg, Man.—The following contracts have been awarded by the good roads board totalling $59,625 in the following municipalities:—Oakland, roads and bridge, to S. Karper, Winnipeg, $5,019. Lansdowne, concrete bridge, to A. Scobie, Winnipeg, $3,864. Glenwood, 29 miles grading, to K. Murcheson, Souris, $31,140. Pipestone, bridge, to W. T. Mauser, Virden, $4,751. Woodworth, bridge, to J. Kelly, Winnipeg, $5,494. Birtle, Portage la Prairie and Morden, bridges, to La Cour & Schoeler, Winnipeg, $3,100, $2,918 and $3,339.

York Tp., Ont.—The township council instructed Engineer Frank Barber to prepare plans for a bridge on Buson Rd.

York Tp., Ont.—The township council will immediately lay a new sidewalk on the north side of St. John's Rd., from Runnymede to Jane St.

York Tp., Ont.—Township council decided to proceed with the extension of Woodville Ave.

York Tp., Ont.—Township council accepted plans for a 24-foot pavement on Pinewood Rd., from High St. to the city limits, and a 28-foot pavement, with a concrete gutter, on Glenholme Ave., from the present pavement to Rogers Rd. Council will probably also construct a number of sidewalks. Engineer, Frank Barber.

York Tp., Ont.—Township engineer Frank Barber was instructed by the council to prepare plans for a bridge on Buson Rd.

Barrett Specification Roof on the Geo. Pattinson Co. buildings, Preston, Ont. General Contractors—P. H. Secord & Sons, Brantford, Ont. Roofer—Brown Jarvis Roofing Co., Brantford, Ont. Architect—J. Micklen, Preston, Ont.

These Buildings all have Roofs that can be *forgotten* for 20 Years!

THE owner of each of these buildings has received from us a Surety Bond, issued by one of the largest surety companies in the world, *guaranteeing their roofs against leaks, wear, and maintenance cost for twenty years.*

Of course, Barrett Specification Roofs do not need this guaranty to make them wear and last. The fact that most of the important buildings in Canada have the Barrett Specification type of roof proves that.

Barrett Specification Roof on the plant of the Pollock Manufacturing Co., Limited, Kitchener, Ont. Architect—C. Cowan. Roofer—Brown Jarvis Roofing Co., Brantford Ont.

Barrett Specification Roof on Athelma Apartments, Toronto, Ont. Roofer—Reggin & Spence, Toronto.

We issue this Surety Bond Guaranty merely as a means of impressing upon you our confidence in Barrett Specification Roofs. The guaranty is your assurance that you have on your building a roof that will need no attention and will give you complete, unqualified satisfaction for twenty years at least, *and probably much longer.* All you need to do to have such a roof is to incorporate in your building specification this sentence: "The roof shall be laid according to The Barrett Specification dated May 1, 1916, and the contractors shall obtain for us the Barrett 20-Year Guaranty Bond."

There is no charge for this Bond. It is obtainable on any roof of fifty squares or larger in towns of 25,000 or more, and in smaller places where our Inspection Service is available.

It will be issued to reputable roofing contractors, approved by us, who use the materials specified and who will agree to examination and approval by our inspectors. Barrett Specification Roofs cost less per year of service than any other kind; they take the base rate of fire insurance; in fact, any way you look at it, a Barrett Specification Roof is the best roofing made for permanent buildings.

A copy of the Barrett 20-Year Specification, with roofing diagrams, sent free on request.

The Barrett Company LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER
ST. JOHN, N.B. HALIFAX N.S. SYDNEY, N.S.

York Township, Ont.—Tenders will be received until noon, September 6th, by the township engineer, for construction of concrete sidewalks on Bernice Crescent, Dennis, Gamble, McRoberts, Poulton and Torrens Ave., also for tarvia pavement on concrete base on Westmount Ave. Frank Barber, engineer, 40 Jarvis St., Toronto. (Official advertisemen in this issue).

WATER, SEWAGE AND REFUSE

Fort Qu'Appelle, Sask.—Contract for boilers for the Saskatchewan Sanatorium has been awarded by the directors to the Vulcan Iron Works, Ltd., Winnipeg.

Hespeler, Ont.—Tenders addressed to M. E. Jardine, town clerk, will be received by the Hespeler water commission up to 5 p.m., August 30th, 1919, for laying approximately 5,448 lineal feet of water mains. Plans and specifications may be seen at the office of the town clerk. Herbert Johnston, consulting engineer, 130 Lancaster St. E., Kitchener, Ont.

Mimico, Ont.—The town council passed a resolution instructing the town engineer to proceed immediately to lay down sewers and water pipes on all streets included in the estimates of council.

Moose Jaw, Sask.—Tenders will be received until 10 a.m., August 30th, by the city council, for laying of approximately 4,600 lin. ft. of 8-in. and 12-in. sewers, and 4,600 lin. ft. of 6-in. and 8-in. water mains. Laying about 650 lin. ft. wood flume, and 1,600 lin. ft. 8-in. cast-iron pipe, and other works. G. D. Mackie, city commissioner. (Official advertisement in this issue).

Peterborough, Ont.—The water commissioners have decided to construct the new filtration plant on the site of the old Carnegie property, Peterborough county. Estimated cost, $200,000.

Pictou, N.S.—Tenders will be received by A. MacDougall, secretary of building commission, Pictou, N.S., until 9 o'clock a.m., Thursday, August 28th, 1919, for excavating, furnishing materials and completing a sewer from the new county asylum to a point on the East river below the Stellarton pumping station. Plans and specifications may be obtained upon application to Geo. A. McHattie, engineer, Acadia Coal Co. office, Stellarton, N.S.

Sandwich, Ont.—The town council intends to construct 4-in. cast-iron water main on parts of Indian Rd., Peter St. and London St. Estimated cost, $7,708.53. E. R. North, clerk.

St. John, N.B.—The common council has decided to extend the water and sewer mains to Alexander Heights.

Stratford, Ont.—City council intends to construct a 9-inch storm sewer on Chestnut St. and a 9-inch sanitary sewer on Railway Ave. R. R. Lang, city clerk.

York Township, Ont.—Surveys are being made for a proposed system of drainage for Todmorden and the eastern end of the township, discharging into the Don River. Reeve Miller.

York Tp., Ont.—Township council decided to construct 6-inch water mains on Morningside, Kingsway and Garboyd Sts., Riverside Drive and Mossom Rd., 5,883 feet in all. Six of these pipes will also be laid between Vaughan Rd. and Hillbrow on Pinewood Ave. and on Atlas Ave., from Hastings Ave. to Vaughan Rd. Other proposals referred to the engineer were a main on Corbett Ave., from Jane St. to the east end, and on Belvidere Ave., from Oakwood Ave. to Alameda Ave., distances of 1,650 feet and 798 feet, respectively.

LIGHT, HEAT AND POWER

St. Thomas, Ont.—The erection of a large concrete dam above the present storage reservoir was discussed by the water commissioners at a special meeting, and immediate action was decided on.

RAILWAYS

Brockville, Ont.—The local board of trade contemplate requesting the board of railway commissioners to have the local Westport-Brockville subdivision of the C.N. Ry. converted into an electric radial. W. A. Lewis, mayor.

St. Thomas, Ont.—The ratepayers of Port Dover, Port Stanley and intervening territory, will request the Hydro-Electric Power Commission to construct a hydro radial through their district.

FACTORIES AND LARGE BUILDINGS

Alberni, B.C.—Tenders addressed to Duncan C. Scott, deputy superintendent general of Indian affairs, department of Indian affairs, Ottawa, will be received up to noon, September 8th, for the construction of an Indian boarding school. Plans and specifications may be seen at the offices of Inspector Cairns, post office building, Vancouver; Chief Inspector Ditchburn, Victoria; Chas. A. Cox, Alberni; W. R. Robertson, Indian agent, Duncan Station, and with the department at Ottawa.

Arnprior, Ont.—Contract let to Sullivan and Lynn, Arnprior, for the erection of a theatre.

Bedford, Que.—Contract has been awarded by the Missisquoi county council, for repairs to county building to J. Morin, Bedford. Contract, cost plus 15%. E. M. J. Lamoureux, secretary-treasurer.

Brockville, Ont.—An agitation is being made for the erection of a modern hotel at Butternut Bay.

Collingwood, Ont.—The Imperial Wire & Nail Co. expect to rebuild their plant which was recently destroyed by fire.

Creston, B.C.—Contract for the erection of a new one-story high school has been awarded to G. Hendrew. Contract price, $1,925.

Creston, B.C.—The directors of the agricultural association have decided to construct a new fair building and skating rink combined. Estimated cost, $1,500.

Brockville, Ont.—The Brockville Paper Manufacturing Co. will erect a 3-story factory on Park St. Estimated cost, approximately $100,000. J. G. Gardner, president of board of trade.

Brantford, Ont.—Contract has been awarded by C. H. Hyman & Co., London, for construction of a four-story reinforced concrete canning factory to P. H. Secord & Sons' Construction Co., Ltd. Contract price, $125,000.

Carbonear, Nfld.—The Bank of Nova Scotia contemplate construction of a new bank building. Estimated cost, $25,000. C. H. Stewart, Toronto, architect.

Chapleau, Ont.—Tenders will be received until September 15th, by the department of Indian Affairs, Ottawa, for construction of an Indian boarding school. Plans, etc., at offices of A. D. McNabb, Indian agent, Sault Ste. Marie; J. T. Godfrey, Indian agent, Chapleau; post offices, Sudbury and North Bay. Duncan C. Scott, deputy superintendent general.

Ford City, Ont.—Contract has been awarded by the Imperial Oil, Ltd., for construction of a storage building, to R. Wescott, Ltd., Windsor. Estimated cost, $25,000.

Galt, Ont.—No contracts have been awarded, as yet, by the housing commission. Tenders recently received were considered too high and were in excess of the limit set by the government.

Guelph, Ont.—The Fried Grills Hat Co. will erect a large addition to their present building, Suffolk St., to be completed by early spring.

Kitchener, Ont.—The Komavar Chemical Co., Cleveland, Ohio, contemplate establishing a Canadian factory. It is stated that a site may be chosen in Kitchener or in London.

Kitchener, Ont.—The Dominion Rubber System has requested the city council to build 200 new houses under the

Burlington Steel Co., Ltd.
Hamilton, Canada

STEEL BARS
For
Concrete Reinforcing

THE MOST IMPORTANT FACTOR IN CONCRETE REINFORCEMENT IS THE TENSILE STRENGTH AND ELASTIC LIMIT OF THE REINFORCING BAR.

OTHER THINGS BEING EQUAL, STEEL HAVING THE HIGHEST ELASTIC LIMIT, OR YIELD POINT, WILL BE THE MOST SATISFACTORY FOR REINFORCEMENT. WHEN UNDER STRAIN, AS SOON AS THE ELASTIC LIMIT OF ANY REINFORCING BAR IS REACHED, THE METAL STRETCHES RAPIDLY DECREASING IN SECTION, DRAWING LOOSE FROM THE CONCRETE AND DESTROYING THE MONOLITHIC BOND EXISTING BEFORE THIS POINT IS REACHED THEREFORE, THE SAFETY OF THE ENTIRE CONSTRUCTION IS IN DIRECT PROPORTION TO THE ELASTIC LIMIT OF THE STEEL USED.

THE ELASTIC LIMIT OF RAIL CARBON STEEL IS 50,000 TO 60,000 POUNDS PER SQUARE INCH, EITHER TWISTED OR PLAIN, AS COMPARED WITH AN ELASTIC LIMIT OF 25,000 TO 30,000 POUNDS IN SOFT STEEL.

THAT'S WHY RAIL CARBON STEEL, WITH ITS 80,000 POUNDS MINIMUM TENSILE STRENGTH, IS RECOMMENDED AS BEING FAR SUPERIOR FOR ALL KINDS OF REINFORCED CONCRETE WORK.

AT OUR HAMILTON, ONT., WORKS WE BUY SELECT RAILS, AND ROLL THEM INTO RAIL CARBON STEEL REINFORCING BARS IN A PLANT WHICH IS THE EMBODIMENT OF THE LATEST THOUGHT AND PRACTICE.

THESE BARS CAN BE SUPPLIED FROM STOCK IN VARIOUS SIZES, LENGTHS AND SHAPES. WE CAN ALSO ROLL SPECIAL SHAPES AND SIZES TO FIT YOUR PARTICULAR REQUIREMENTS.

Bars bent to shape for Beams, Stirrups, Etc.

PROMPT SHIPMENT

Housing Act. The company, it is understood, would be willing to give a guarantee by which the city might ask for repayment of loan.

Kitsilano, B.C.—Contract has been awarded by the school board for construction of a new high school to E. Crystal & Co. Contract price, $15,483.

Listowel, Ont.—The construction of a $10,000 rink is under consideration. Clerk, Wm. Bright.

London, Ont.—A proposed memorial hall for London, Ont., will be voted upon by the ratepayers next January. Mayor Somerville.

Loretteville, Que.—Tenders will be received until noon, August 23rd, for construction of an Anglican church. Staveley & Staveley, architects, 92 St. Peter St., Quebec, Que.

Moncton, N.B.—Tenders addressed to C. R. Brown, chief engineer, C.N.R., Moncton, N.B., will be received up to 12 o'clock noon, Monday, August 25th, 1919, for the construction of a frame express building, 110 ft. long. Plans and specifications may be seen at the following offices: Chief engineer, Moncton, N.B., terminal agent, C.N.R., St. John, N.B.

Montreal, Que.—La Presse Publishing Co., Ltd., contemplate construction of a new building at the corner of Craig St. and St. Lawrence Blvd.

Montreal, Que.—Plans are being prepared for construction of a nurses' home at the Western Hospital. R. G. Rea, 285 Beaver Hall Hill, architect.

Moose Jaw, Sask.—City council decided to erect an aerodrome in Lynbrook Heights at a cost of $1,750.

Outremont, Que.—The council has awarded contracts for construction of 12 houses to be build on Peronne Ave., on city property. Contract price, $119,400.

Perdue, Sask.—Contract has been awarded by the school board for construction of a new brick school to F. C. Taylor. Contract price, $20,000. J. M. Morrison, architect, Saskatoon.

Port Colborne, Ont.—It is expected that work will commence on reconstruction of part of the government elevator recently partially destroyed by explosion.

Port Hope, Ont.—Tenders will be received by Ellis & Ellis, architects, Manning Chambers, Toronto, up to and including August 30th for proposed extensions and new buildings at the Port Hope Hospital. Plans and specifications may be seen at the office of the town clerk, Port Hope, Ont., and at the office of the architects.

Prince Albert, Sask.—The directors of the Fair Board contemplate the construction of a new grand stand and improvements to the stables. W. O. McDougall, manager.

Quebec, Que.—It is understood that plans are being prepared for a new wing to the parliament buildings, to be built on St. Julia St.

Quebec, P.Q.—It is reported that an option has been taken upon property situated around Sillery Cove for its eventual purchase for the erection of a nine million dollar pulp mill. The promoters are well-known American financiers and practical pulp mill men.

Redcliff, Alta.—Plans are completed for the erection of two large additions to the Dominion Glass Co.'s plant here.

Regina, Sask.—The board of directors of the Regina exhibition will construct an additional 90 ft. to the grandstand. Estimated cost, $25,000. The present bleachers will also be reconstructed.

Regina, Sask.—The city commissioners have decided to forward claim to the receiver of the G.T.P. Ry., asking that company to fulfill its agreement with the city, to erect a million-dollar hotel and a quarter-million-dollar station, for which valuable concessions were granted the railway company in 1911 and 1912.

Regina, Sask.—Contract has been awarded by the commissioners of the R.N.W.M.P. for construction of a new barracks on the southwest corner of the barracks square to the Poole Construction Co. Contract price, $72,000.

Sandwich, Ont.—A Detroit company manufacturing clutches for automobiles, trucks and tractors has secured a site here and proposes to erect a branch plant. Building operations will not be commenced until next year.

Sarnia, Ont.—Herbert Weil and W. J. Reid, of Port Huron, Mich., are planning the erection of a large theatre here.

Saskatoon, Sask.—Tenders will be received until noon, August 25th, for construction of a freight office and extension to freight shed. Plans, etc., at offices of district engineers at Saskatoon and Edmonton. J. Schofield, architect for the C.N. Ry., room 459, Union Station, Winnipeg, Man.

St. Catharines, Ont.—Tenders will be received until 5 p.m., August 22nd, by the suburban road commission for construction of approximately one and seven-tenths mls. of pavement, 18 ft wide, on Ontario St., from St. Catharines to Port Dalhousie. Tenders will be considered for any standard pavement, such as cement concrete, tar macadam or any bituminous surface. W. B. Burgoyne, chairman.

Sydney, N.S.—The Rhodes Curry Co., have been awarded the contract for the construction of the new Holy Redeemer church at Whitney Pier. Architects, Chappell and Hunter, of Charlottetown, P.E.I. Estimated cost, $160,000.

Toronto, Ont.—City Architect Pearse has issued a permit to R. Thornton for an addition and alteration to motion picture theatre on Mavety St., at a cost of $21,000.

Toronto, Ont.—The York Township Housing Commission will receive tenders until August 20th, for construction of seven houses. J. A. Martin, secretary, 40 Jarvis St.

Toronto, Ont.—The King Suspender Co. have purchased site at 129 to 139 Spadina Ave., and will erect a new factory building. Estimated cost, $135,000. H. Greisman, president.

Trenton, Ont.—Tenders will be received until 6 p.m., September 1st, by the Trenton housing commission, for construction of 27 houses. Wm. Lyon Somerville, architect, Imperial Bank Building, Yonge and Bloor Sts., Toronto.

Vancouver, B.C.—The school board will shortly submit a by-law to the ratepayers for $465,000. Included in this amount, Dawson school completion, $72,000; Kitsilano high school, $30,000; temporary additions to schools, $78,000, and proposed technical school, $200,000.

Windsor, Ont.—The ratepayers have voted against the proposed by-law granting certain concessions to the Lamb Railway Service Co., including two-thirds of an acre in the factory district, in return for construction of a $10,000 factory.

Windsor, Ont.—The chamber of commerce has announced the decision of the Fisher Body Co., of Detroit and Walkerville, to establish a branch plant in Canada for the manufacture of closed automobile bodies. A five-story building will be erected in the near future here.

Winnipeg, Man.—Winnipeg's $1,000,000 housing scheme will be proceeded with immediately.

York Township, Ont.—Township Council has been asked to provide for a $60,000 addition to the school in S.S. 26 at the corner of Barrington and Secord Avenues. Clerk W. A. Clarke.

York Township, Ont.—Tenders will be received until 12 o'clock noon, August 25th, by the township council for construction of a reinforced concrete bridge, 18-ft. span, on the 3rd concession east of Yonge St, near Duncan Station; two reinforced concrete culverts on Horseham and Hounslow Ave.; concrete truss bridge on Buson Rd. Frank Barber, engineer, 40 Jarvis St.

MISCELLANEOUS

Boisdale, N.S.—Tenders will be received until 12 o'clock noon, September 3rd, by the Department of Public Works, Ottawa, for construction of a wharf at Boisdale, N.S. Plans, etc., at offices of district engineer, North Sydney, N.S., and at post office, Boisdale, N.S. R. C. Desrochers, secretary.

Connaught Station, Ont.—The timber pilework wharf, for which tenders were called for noon, July 15th, by the

Branches: Toronto, Winnipeg, Regina, Calgary, Vancouver

Department of Public Works, Ottawa, will be constructed by day labor. R. C. Desrochers, secretary.

Cornwall, Ont.—Tenders will be received until 12 o'clock noon, August 26th, by the Department of Railways and Canals, Ottawa, for improving upper entrance to lock 18. Plans, etc., at offices of chief engineer, Ottawa, and superintending engineer, Cornwall, Ont. J. W. Pugsley, secretary.

Ingersoll, Ont.—The park committee have decided to construct a reinforced concrete retaining wall along the north end of the new park.

Laprairie, Que.—Tenders will be received by the department of public works until 12 o'clock noon, August 28th, for protection works at Laprairie, county of Laprairie, Que. Plans, etc., at offices of district engineers, Shaughnessy Building, Montreal, and post office, Quebec, and at the post office, Laprairie, Que. R. C. Desrochers, secretary.

Morden, Man.—Tenders will be received until August 23rd, by Stanley municipal council, for construction of reinforced concrete culvert, north of section 1-1-6 W. C. McCorquodale, secretary-treasurer.

New Glasgow, N.S.—Tenders for plumbing for the nurses' home in connection with the Aberdeen Hospital, will be received by J. C. McGregor, up to Tuesday, August 26th. Plans and specifications may be seen at the office of J. W. Carmichael and Co., New Glasgow.

Peterborough, Ont.—City council contemplates purchase of one or two power street flushers. City engineer, R. H. Parsons.

Pincher Creek, Alta.—At a joint meeting of the United Farmers' Association, and the ratepayers, the following resolution was adopted: That the Dominion government be requested to make this summer, a survey to determine the feasibility of constructing irrigation works to irrigate the Summerview district, the Cowley district, the Pincher Creek flats and the district south of Pincher Creek. H. E. Hyde, mayor, Pincher Creek.

Prince Rupert, B.C.—Contract has been awarded by the marine department for construction of a steel and concrete lighthouse on Triple Island to J. H. Hilditch.

Saskatoon, Sask.—Contract has been awarded for installation of one 4,000,000 gallon pump, head 102 ft.: one 1,000,000 gallon and one 4,000,000 gallon pump, head 40 ft., by the city council, to Goldie & McCullough Co. Contract price, $11,176. Rejected tenders, Turbine Equipment Co., $11,010; Canadian Allis-Chalmers, $11,815. G. D. Archibald, engineer.

St. Jean d'Orleans, P.Q.—Tenders addressed to R. C. Desrochers, secretary, department of public works, Ottawa, will be received until 12 o'clock noon, Wednesday, September 3, 1919, for the construction of repairs to wharf at St. Jean d'Orleans, county of Montmorency, Que. Plans and forms of contract can be seen and specification and form of tender obtained at the department of public works, Ottawa, and at the offices of the district engineers, Post Office Building, Quebec, Que., Shaughnessy Building, Montreal, Que., and at the post office, St. Jean d'Orleans, Que.

St. John, N.B.—Contract has been awarded by the common council for terra cotta pipe as follows: 800 ft., 12 in., $52.10 per 100 ft., to Jas. Robertson Co., Ltd.; 1,200 ft., 9 in., to T. McAvity and Sons, Ltd.

Sydney, N.S.—The Sydney Foundry and Machine Co. is applying for a site on which to construct a drydock for this port.

Toronto, Ont.—Local improvement by-laws will be considered at a special meeting of the city council to-night for work amounting to over $700,000. According to Assistant City Engineer Powell, in the event of all the by-laws being passed by council, a great amount of the work will be started immediately, and will be completed this year.

Toronto, Ont.—Tenders addressed to T. L. Church, mayor, chairman, board of control, City Hall, Toronto, will be received up to noon on Tuesday, August 26th, 1919, for the complete supply and erection of metal fire escapes on the Isolation Hospital Buildings. Specifications, etc., may be seen at the office of the property department, City Hall.

Toronto, Ont.—Tenders will be received until 12 o'clock noon, September 5th, by the Department of Public Works, Ottawa, for provision and installation of interior fittings in terminal postal station "A," Toronto. Plans, etc., at offices of chief architect, Ottawa; resident architect, 61 Front St. West; superintendent of Dominion public buildings, postal station "F," Toronto, and overseer Dominion buildings, central post office, Montreal, Que. R. C. Desrochers, secretary.

Trail, B.C.—The city council has awarded contract for 1,500 lin. ft. of four-inch steel water pipe and six four-inch gate valves, to Gordon & Belyea, Vancouver, B.C.

Vancouver, B.C.—The board of works contemplate construction of a pivot pier and protection fenders for the Granville St. bridge. City Engineer Fellowes.

Vancouver, B.C.—The city council has authorized the purchase of an American La France gasoline pumping engine for the fire department at a cost of $15,650.

Wallaceburg, Ont.—It is understood that the Great Lakes Refining Co., Wallaceburg, have purchased a property and will erect a number of storage tanks.

Weston, Ont.—The Weston council has decided to call for tenders for a fully equipped motor truck, with chemical appliances, for the fire department. Fire Chief Pollard.

Windsor, Ont.—The ratepayers have voted against the proposed by-law to provide $15,000 for a fire engine and $20,000 for two motor flushers.

Winnipeg, Man.—Tenders will be received by the C.N. Ry. until August 25th, for construction of turntable foundations at Kamsack, Sask., and Dauphin, Man., for track-scale foundations at North Battleford, Sask., Big Valley, Sask., and Swan River, Man. Plans, etc., at offices of the district engineers at Saskatoon and Edmonton. J. Schofield, architect, room 459, Union Station, Winnipeg.

Tenders Called For

TOWN OF HESPELER

WATERWORKS EXTENSION

Sealed tenders addressed to M. E. Jardine, Town Clerk, Hespeler, will be received by the Hespeler Water Commission up to 5 p.m., August 30, 1919, for laying approximately 5,448 lineal feet of water mains.

Plans and specifications may be seen at the Office of the Town Clerk, Hespeler, Ontario.

The lowest or any tender will not necessarily be accepted.

HERBERT JOHNSTON,
Consulting Engineer.
130 Lancaster St. E., Kitchener, Ontario. 328

TENDERS FOR PAVEMENT

Sealed tenders, marked "Tenders for Pavement," will be received by the undersigned up till 12 o'clock noon, Friday, August 29th, for the construction of approximately 1,550 lineal feet of curb and gutter; 4,300 square yards of Asphalt, Asphaltic Concrete or Bitulithic pavement on 6-in. Concrete Base.

Tenderer to submit prices for standard Asphalt, Asphaltic Concrete or Bitulithic pavements.

Plans and all necessary information may be obtained at the office of the City Engineer, City Hall.

A marked cheque made payable to the City Treasurer of five per cent. (5%) must accompany each tender.

The lowest or any tender not necessarily accepted.

C. B. SYMES,
City Engineer. 325

Fort William, August 14th, 1919.

The Canadian Engineer

A Weekly Paper for Civil Engineers and Contractors

Progress of Queenston-Chippawa Power Canal

Nearly Five Million Cubic Yards of Earth and Rock Removed—Huge Shovel Establishes Record in Loading 8,500 Cubic Yards on Cars in 20 Hours—Extensive Construction Railway Handling 200 Trains Daily—Payroll Only 1,000 Men Per Shift—Construction Equipment Worth Several Million Dollars

WITH several million dollars' worth of equipment on the job, and a pay roll of 2,000 men, the Hydro-Electric Power Commission of Ontario is making rapid progress on the Queenston-Chippawa power development. The construction organization has been perfected, any probable difficulties in excavation have been adequately met, the overburden has been stripped from nearly half the length of the canal, considerable rock has been taken out, the forebay is nearing completion, the power house site has been cleared, the construction railway into the power house site is being graded, the hydraulic turbines and the generators are under construction; in brief, it is now almost solely a matter of digging, channeling, drilling and blasting to complete what will probably be the largest and one of the most efficient hydro-electric plants in the world, developing at least 300,000 h.p. under 305 ft. average net head.

In the June 20th, 1918, issue of *The Canadian Engineer*, pages 545 to 550 inclusive, appeared an article which dealt with the economics and design of this development. In the September 26th and November 21st, 1918, issues respectively appeared brief descriptions of the proposed turbines and generators. The present article is intended primarily to deal with the methods of construction and the progress that has been made to date.

POWER-HOUSE SITE CLEARED—VIEW FROM THE UNITED STATES BANK OF THE NIAGARA RIVER—LEWISTON BRIDGE, ABOUT A MILE DOWNSTREAM, CAN BE SEEN AT EXTREME RIGHT OF PHOTO

Referring to the accompanying profile, it will be noted that the canal is entirely in rock excepting from about Sta. 335 to Sta. 350, near the Whirlpool, and from Sta. 0 to Sta. 40, adjacent to the Welland river.

From Sta. 273 (Niagara, St. Catharines & Thorold Railway) to Sta. 460 (the forebay) the canal section has been entirely stripped to rock with the exception of a small amount of work remaining to be done near the Whirlpool gully. Three electrically-driven shovels are at work removing the overburden between Sta. 100 and Sta. 273. With the exception of pilot cuts, practically no earth has been moved between the Welland river and Sta. 200. Rapid progress is being made with the Welland river section of the work, which is being handled by a dredge and a cableway excavator.

A large quantity of rock has been removed at the forebay and between the forebay and Sta. 273.

There are ten power shovels at work on the canal, all manufactured by the Bucyrus Co. The three largest are electrically-driven, each being equipped with an 8 cu. yd. bucket for excavation in earth, and each weighing 400 tons. There are also three electrically-driven shovels each equipped with buckets of 4½ cu. yds. capacity, and one electrically-driven shovel (with caterpillar traction) equipped with a ⅞-yd. bucket. There are three steam shovels, one having a bucket of 2 yds. capacity, one 1-yd. and one ⅞-yd., the latter two having caterpillar traction.

An 8-yd. shovel is at work at the forebay removing the rock to a depth of about 45 ft. The first lift of rock has been entirely removed to a width of 300 ft. at the gate house and the remainder of the rock to the necessary depth has been drilled and blasted to a total width of 500 ft. at the gate-house and is now being loaded by the shovel. Tracks have been laid on top of the blasted rock, at an elevation about 30 ft. above the shovel's tracks, and the electrically-hauled trains of dump cars are run over the rock directly to the shovel.

Between the forebay and Sta. 273, two other shovels are working in rock, one 8-yd. and one 4½-yd. capacity. It should be stated that these capacities, as well as those mentioned above, are the capacities of these shovels in earth. The capacities in rock are, of course, proportionately smaller. For example, each 8-yd. shovel has a capacity of 5½ cu. yds. in rock.

The two shovels that are working in rock between the forebay and Sta. 273, started at Station 295 and are going in opposite directions, the big one working toward the Welland river and the 4½-yd. shovel going toward the forebay, both working on the first lift of rock.

Channeling, drilling and blasting proceeds almost incessantly, day and night, ahead of the shovels. The shovels are being operated by two shifts of ten hours each, an adequate equipment of flood lamps providing plenty of illumination for carrying on the work at night.

A 4½-yd. shovel is at work at the Whirlpool cleaning up the bottom preparatory to the riprap construction.

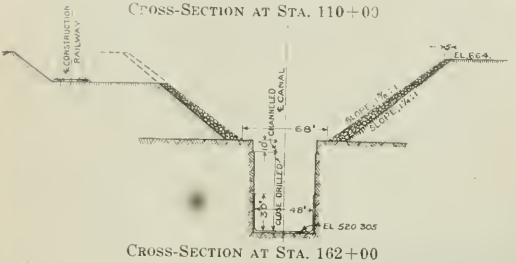
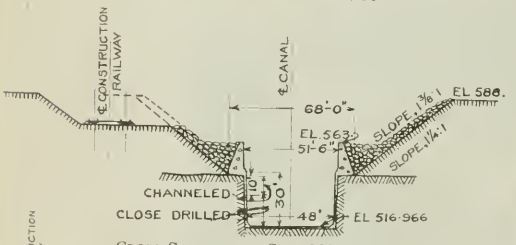
Cross-Section at Sta. 110+00

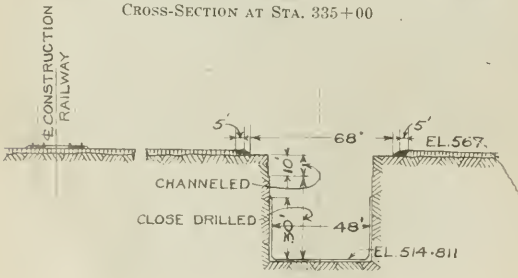


Cross-Section at Sta. 162+00



Cross-Section at Sta. 320+00

Cross-Section at Sta. 335+00



Cross-Section at Sta. 422+00

The 1-yd. shovel is working toward the Welland river, south of Sta. 323 (the Grand Trunk bridge), cleaning the rock preparatory to channeling.

Between the Niagara, St. Catharines & Thorold Railway (Sta. 273) and Muddy Run creek (Sta. 200), there are

Battery of Rand and Sullivan Rock Drills at the Forebay

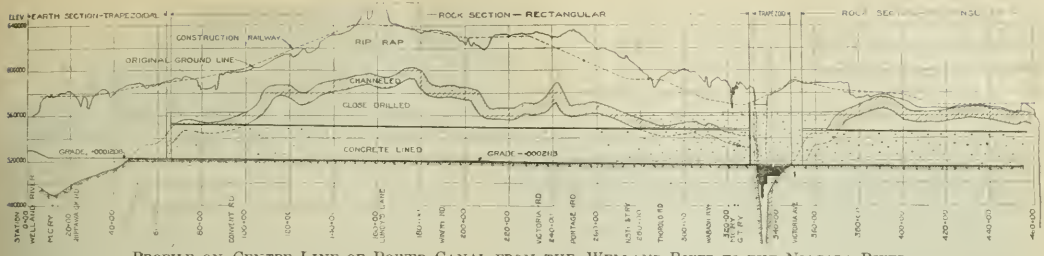
three shovels working in earth: One 8-yd. shovel, one 4½-yd. and one 2-yd.

The steam-driven ⅞-yd. shovel is working south of Muddy Run, digging pilot cuts, ditching, loading, ballasting and doing other miscellaneous preparatory work. The electrically-driven ⅞-yd. shovel is grading the construction railway from Queenston to the power-house site.

Among the other plant on the job are 21 electric locomotives, 7 steam locomotives, 150 twenty-yard Western steel dump cars, 50 sixteen-yard Western wooden dump cars, 12 box and flat cars, one 5-yd. dredge, one Ligerwood cableway excavator (800-ft. span), 2 draglines each equipped with a

Crane Moving Rock in Skips from Canal Section at Entrance to Forebay

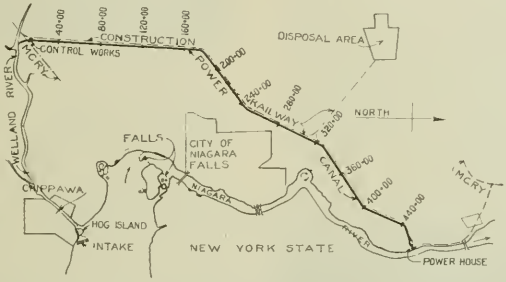
one-yd. bucket, 2 White motor dump trucks, 1 Sawyer-Massey traction engine, 10 Troy 3-yd. dump wagons, 1 Sawyer-Massey road scraper, 3 Bay City cranes of 40-tons capacity at 16½ ft. radius, 2 Bay City cranes of 15 tons capacity at 16½ ft. radius, 2 London concrete mixers, 4 Ransome concrete mixers, 1 Wettlauffer concrete mixer (each of these 7 mixers having a capacity of approximately 1 cu. yd. of mixed concrete), 2 cement-guns of the N-2 type, 1 Ransome grout mixer, 1 McKenna bar bender, several Sterling concrete carts, 1 Stephens-Adamson crushed stone conveyer, 75 Sullivan rock drills, 8 Ingersoll-Rand rock drills, 2 Leyner oil furnaces, 3 Sullivan drill sharpeners, 1 McKiernan-Terry pile hammer, 1 Vulcan pile hammer, 1 Beatty clam-shell bucket, 1 Hayward orange-peel bucket, 1 Orton & Steinbrenner ¾-yd.



PROFILE ON CENTRE LINE OF POWER CANAL FROM THE WELLAND RIVER TO THE NIAGARA RIVER

bucket, 1 Hayward 1½-yd. clam-shell bucket (motor driven), 1 Andresen-Evans 3-yd. bucket (on cableway excavator), 12 Sullivan channellers, 1 McCully No. 5 gyratory crusher, 2 McCully No. 6 gyratory crushers, 1 McCully No. 7½ gyratory crusher, 2 Barber-Green 60-ft. portable conveyors, 1 Traylor 60-in. by 84-in. steel jaw crusher, 36 thousand-watt Davis flood lamps, 13 four-hundred-watt Lyman flood lamps, 2 Napance hoists, 1 Ligerwood hoist, 1 Beatty hoist, 2 Jordan spreaders, 2 Imperial tie tampers, 1 double-track snow plow built by Canadian Steel Foundries, numerous Herbert Morris hoists, 2 Lincoln track bonders, numerous Norton Jacks and a large quantity of valves, hydrants, pipe, tanks, standpipes, searchlights, transformers, motors, etc. There are about 36 pumps of various types and capacities, a few of which are operated continuously, the others being held for emergencies and intermittent use.

The job is equipped with its own telephone system, which also is connected by private wire direct to the head office of the Hydro-Electric Power Commission in Toronto, and with its own water distribution system and electric light system.



PLAN OF QUEENSTON-CHIPPAWA POWER CANAL

Fifty-five miles of construction railway have been built, including yards, sidings, etc. The 2½ miles of railway from the canal to the disposal area is one of the busiest double track lines in America, carrying from 180 to 200 trains (of ten cars each) daily during the 20 working hours. A despatching system, controlled by telephone, has been found necessary, especially at night.

In the Whirlpool yards are located a large machine shop, store houses, cement stores, forges, etc. The list of equipment above mentioned does not include the many machine tools, trip-hammers, wood-working machines, welding outfits, etc., with which these buildings are equipped nor the thousand and one items with which the store-houses are filled to the roofs in orderly bins and racks, including everything that might possibly be needed, from safety pins and iodine to dynamite and structural steel.

The main transformer house is at station 320. Here are installed 12 Sullivan air compressors, each having a capacity of 1,000 cu. ft. per minute against 125 lbs. pressure. The installed transformer capacity at the station is about 7,500 k.v.a., of which 3,000 k.w. is direct current.

Another transformer house is being erected at Sta. 90. A small transformer house was erected near Chippawa at the beginning of the work for the purpose of supplying the Welland river section. All power is obtained from the Ontario Power Co., which is now controlled by the Hydro-Electric Power Commission. The compressed air is used for operating the drills and channellers and for numerous small tools. It is piped in double 8-in. and single 10-in. lines, with valves every 500 ft.

The first shovel on the job was the 2-yd. Atlantic type shovel, which began work in the spring of 1917 at Sta. 324. Since then there has been removed to date a total of a little more than 4,000,000 cu. yds. of earth and 500,000 cu. yds. of rock. The excavating plant has been increased continuously, two of the largest shovels having been received only a few months ago, and the work is now progressing 50% faster than previously. Since January 1st, 1919, approximately 2,200,000 cu. yds. of earth and 350,000 cu. yds. of rock have been removed, partly by the dredge, partly by the cableway excavator and partly by miscellaneous equipment, but mostly by the shovels.

The best day's record for any one shovel was the loading of 420 cars in two 10 hr. shifts, this being equivalent to 8,500 cu. yds. bank measurement.

The total amount of material to be excavated from the canal section is 9,000,000 cu. yds. of earth and 4,000,000 cu.

CHANNELERS AT WORK—AT LEFT, STA. 316+25—AT RIGHT, STA. 419+00, SHOWING TRAVELLING SMITHY MOUNTED ON TRUCKS

Two Views Showing Channel Cut—At Left, Sta. 443+00, Looking West—At Right, Sta. 448+00

yds. of rock; and from the river section, 2,000,000 cu. yds., mostly earth. These figures include the work already done.

The heavy rock fill section across the Whirlpool gully, illustrated on page 250 by the section at Sta. 335+00, is in an advanced stage of construction, approximately 50% of the rock being already in place. Behind the rock fill the whole of the gully is being backfilled with earth to the extent of 1,500,000 cu. yds., 80% of which is now in place. Each rock fill flanking the canal at this point has the following dimensions: Length at top, 650 ft.; length at base, 350 ft.; width at top, 20 ft.; width at base, 160 ft. Between these

Jordan Spreader Pushing Back Dumped Earth at St. David's Disposal Area

rock fills the base of the canal section is backfilled with rock to a depth of 8 ft.

Incidentally it may be mentioned that the filling of the Whirlpool gully and its offshoots will reclaim a considerable tract of land that will ultimately be of great value for factory sites.

The power-house site, which is at the foot of the steep cliff just above the Lewiston bridge, was difficult of access. An electric shovel is now cutting its way from Queenston to the power-house site, along the bank of the river, about 30 ft. above normal water level. Besides cutting its own path, the shovel is doing the necessary grading for the construction railway, which will run right into the power-house site.

As can be seen from the sketch on page 255, this construction railway connects with the Michigan Central, making use of a portion of the International Railway's present tracks and also of the new tracks that will be built by the International Railway. This new route will give the International Railway a better approach, having a much less dangerous grade, to the Queenston dock, and will also permit the use of the large gully south of the dock as a dump for the material excavated from the power-house site.

The construction railway has been completed from the forebay to Sta. 170, and to the disposal area at St. David's. It has also been constructed from the Welland river to Sta. 40, and will soon be connected between Sta. 40 and Sta. 170. Switching arrangements have been completed at the Welland river for interchanging traffic with the Michigan Central's Welland-to-Niagara Falls line.

The channel south of Hog Island, where the intake will be constructed, is being widened and deepened, and this work is practically completed. The dredge is now working in the Welland river digging out the piers of the old highway bridge. The dredged material is floated down the Niagara river on scows and dumped. An "unloader" is moored to a stone-filled crib in the river, and the scows are controlled by the steel wire cable running from the drum of this "unloader," with the result that only two tugs are required to guide each loaded scow and "spot" it over the dumping site; moreover, the chance of a scow breaking loose from the tugs and going over the Falls is largely obviated.

Train Unloading at St. David's Disposal Area—Note Low-Lying Grounds at Left, Providing Dump 200 Acres in Extent

The towers for the cableway, which is being used to a great extent in the widening of the Welland river, run on standard gauge tracks. Each tower has two tracks at 40-ft. centres and hauls itself along by its own motor by means of a line to a deadman. No work has been done as yet on the control works at the junction of the canal with the Welland river, nor in connection with the intake itself.

Prof. R. W. Angus, of the University of Toronto, has been engaged this summer and last summer in experiments with hydraulic similarity models at Dufferin Islands, near the Ontario Power Co.'s intake in the Niagara river; and the Chippawa intake, which will extend into the river from Hog Island, as roughly indicated on the plan on page 251, will be built in accordance with the results of these experiments.

It is likely that this structure will be of concrete, so designed as to be able to take the water from the bottom of the river whenever desirable in order to avoid ice.

The control works near the junction of the canal and the Welland river will consist mainly of Stoney sluices, so arranged that the canal can be unwatered at any time in case of emergency.

Experiments are now being conducted regarding the relative efficiencies of concrete and gunite (the sand-cement

⅞-Yd. Shovel at the G.T.R. and M.C.R. Diversion

product shot by cement-guns) linings for the portions of the canal that are in rock. It has not yet been fully decided by what method, or to what extent, the canal will be lined. Wherever the canal is in rock, however, it will be lined to a height of at least 30 ft. from the bottom, and in the earth sections it will be lined everywhere to El. 563. At the Welland river for example, the bottom of the canal is approximately at El. 523, so the sides there will be lined for a height of 40 ft.

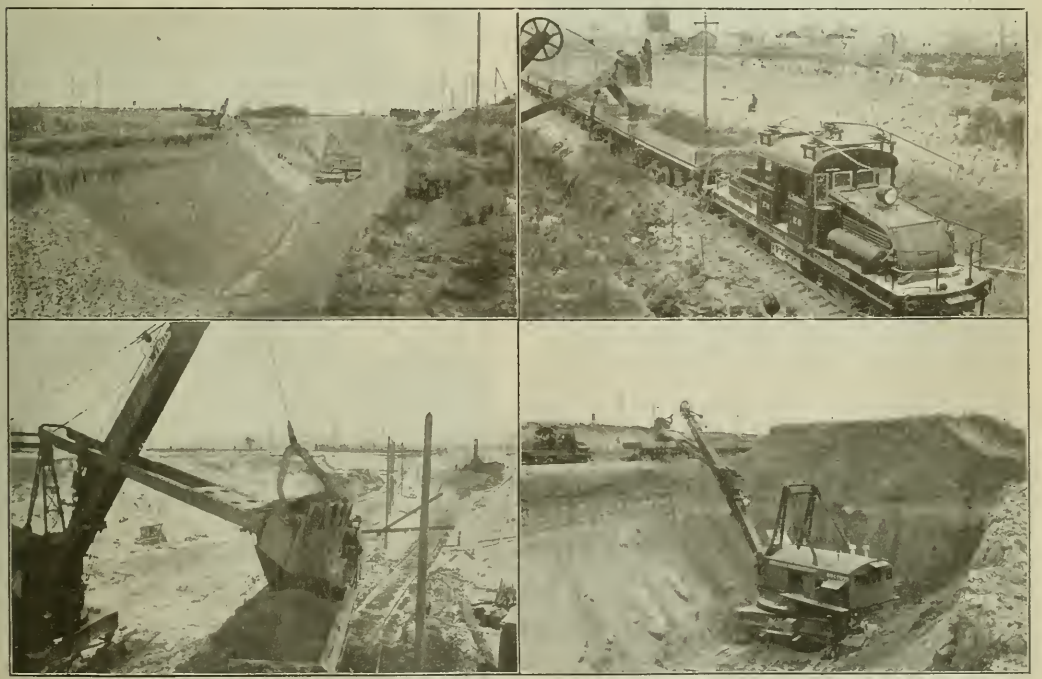
Over 130 buildings have been built, moved or repaired

4½-Yd. Shovel in Rock at the Forebay

during the course of construction to date. Most of the new buildings are of a temporary nature.

Among other work which is being carried out by the commission to remedy the changes in the landscape that are being caused by the power canal, is the construction of several bridges.

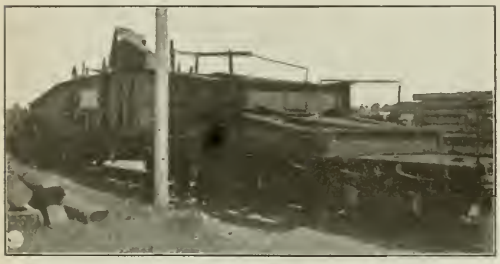
A reinforced concrete arch, 86-ft. span, to carry the Niagara, St. Catharines & Thorold Railway across the canal,



Four Views of One of the 8-Yd. Shovels Working in Earth—Top Left Photo Shows Some Rip Rap in Place—Top Right, Train Being Loaded at Sta. 346+81—Bottom Left, Working South of the Wabash R'y—Bottom Right, Working Against a High Face at Sta. 346+81

Crusher Plant—Primary Traylor Crusher at Left, Gyratories in Centre, Screens About to be Erected at Right—Capacity, 3,500 Cu. Yds. Daily

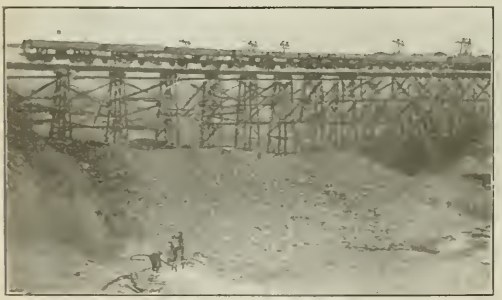
is practically completed. An arch of 100 ft. span has been built to carry the Wabash Railway. Where the Grand Trunk Railway and the Michigan Central Railway cross the line of the canal, the tracks are only about 90 ft. apart; therefore, with a view to future requirements, the skew arches that will carry these railways across the canal will be carried though, making one continuous structure and providing ample room for additional tracks. These two railways have been temporarily diverted during the con-



The Bethlehem Steel Co.'s Special Artillery Truck Was Required to Carry the Massive Parts of the Traylor Jaw Crusher

struction of this bridge, and work has begun on the foundations.

The N. St. C. & T. R'y bridge involved the diversion of the existing single track to one side of the bridge site and the construction of a double track reinforced concrete arch with 86 ft. span, having a rise of 25 ft. This arch was designed for Coopers' E-60 loading, and contains approximately 3,500 cu. yds. of concrete and over 90 tons of steel. The depth from base of rail to foundations is 52 ft. Lackawanna sheet piling was driven around the abutments, cofferdams were unwatered and material excavated to required depth after a great deal of trouble was caused by the satura-



Dumping Rock from Trestle for Fill at the Whirlpool Gully

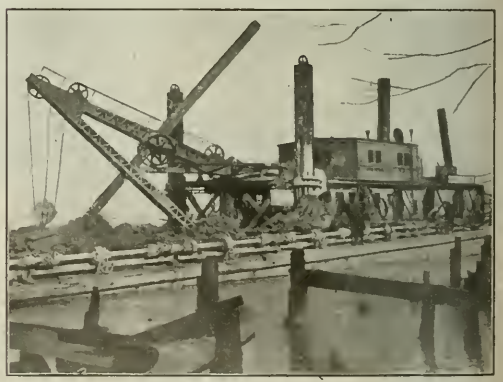
tion of the surrounding subsoil. The arch was completed and traffic restored to the original alignment last December. A temporary timber trestle was designed to carry the N. St. C. & T. R'y line over the construction railway tracks, which are in the canal prism and parallel to the centre line of the canal.

The Wabash line was diverted on a timber trestle over 40 ft. high, extending across the previously excavated canal section. The excavation of the canal prism thus provided natural drainage for the foundations for the 100-ft. reinforced concrete arch. This arch differs in design from the N. St. C. & T. R'y arch, as the Wabash arch has straight wing gravity walls instead of the reinforced cantilever type

Scow-Lowering and Rehauling Outfit at Work on the Niagara River

used in the other arch. There are approximately 3,000 yds. of concrete and 65 tons of reinforcing steel in the construction. The structure provides for two tracks, spaced 13 ft. centres, which will take care of the requirements of that railway for many years. The main line tracks of the Wabash are also carried over the construction railway by means of a temporary trestle.

A 3-track trestle about 400 ft. long has been built for the diversion of the main line of the Grand Trunk and the branch line of the Michigan Central. Upon completion of the



Dredge at Work on the Welland River

outside portions of the new arch, it is intended to re-divert traffic to the present alignment. The new structure will be a reinforced concrete arch, having a span of 72 ft. and rise of 20 ft. and involving the placing of 10,000 cubic yards of concrete and 325 tons of steel. It will provide room for 10 tracks. In the restoration of the G.T.R. and M.C.R. to the original alignment, a temporary timber trestle will carry the tracks over the construction railway. The trestles for diversion and relocation of these railways involve the use of over 300,000 ft. of timber.

View from East End of Lewiston Bridge, Showing Nature of the Cliff Along Which ⅞-Yd. Electric Shovel is Cutting Path for Construction Railway, 30 Ft. Above Water Level

The completion of these three arches will greatly assist the progress of excavation, as the equipment will then be free to move to any point, and the innumerable delays occasioned by the railways will be entirely eliminated, and the output of the excavating equipment will not be hampered in its course to the disposal area.

At Lundy's Lane, the highway is now being diverted to the north to a point where the construction railway is at the same elevation as the original ground line. This is preparatory to making the cut at Lundy's Lane, after which a highway bridge will probably be constructed across the canal at a point most favorable in respect to grades and detours.

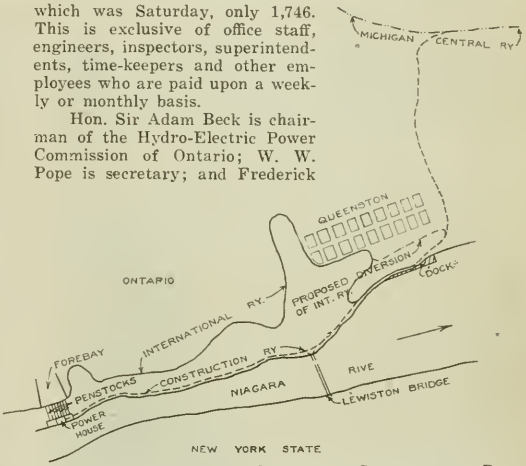
Two new bridges must be built across the Welland river on account of the enlargement of that stream. These bridges will be of steel, and excavation is now in progress for their foundations. The Michigan Central Railway bridge will be a

Looking Across Niagara River from Hog Island—The Intake Will Extend Into the River from this Island

swing span, and the highway bridge will be a bascule, with a 90-ft. leaf.

The number of men on the daily pay-roll varies considerably; for instance, on August 14th, 1919, exactly 1,884 men reported for work; the following day, 1,905; on August 16th, which was Saturday, only 1,746. This is exclusive of office staff, engineers, inspectors, superintendents, time-keepers and other employees who are paid upon a weekly or monthly basis.

Hon. Sir Adam Beck is chairman of the Hydro-Electric Power Commission of Ontario; W. W. Pope is secretary; and Frederick



Plan Showing Route of Queenston Construction Railway now Being Graded, and Proposed Diverson of International Railway's Line to the Dock

A. Gaby is chief engineer. The design and construction of the Queenston-Chippawa project, with the exception of the electrical work, are under the direction of the Commission's hydraulic department, of which Henry G. Acres is the hydraulic engineer; Thos. H. Hogg, assistant hydraulic engineer; and Max V. Sauer, designing engineer.

E. T. Brandon is the electrical engineer of the Commission; and Arthur H. Hull, assistant electrical engineer.

At Niagara Falls there is a large staff under the direction of J. B. Goodwin, works engineer, and of George Angell, general superintendent of construction. A. C. D. Blanchard

Looking Up the Welland River, Hog Island at the Right—Before and After Widening the Intake Channel of the Canalized River Section

DREDGING THE WELLAND RIVER—A BUCKETFUL

is chief field engineer; Francis W. Clark, division engineer in charge of the intake, river section and canal; and Walter Jackson, division engineer in charge of the forebay and power-house. The resident engineers are W. S. Orr, Division No. 1 (river section); C. H. McDougall, Division No. 2 (Welland river to Sta. 235); and George H. Lowry, Division No.

THE CABLEWAY EXCAVATOR HAS AN 800 FT. SPAN

3 (Sta. 235 to Sta. 438). Channel Anderson is superintendent of Division No. 1; F. W. Scriven, of Division No. 3; and W. L. LeRoy, of Division No. 4 (forebay, power-house and Queenston construction railway). Harold L. Bucke is superintendent of railway construction; R. T. Gent, plant engineer; P. Reid, mechanical superintendent; and F. F. Cooper, chief clerk.

Arrangements have now been practically completed whereby the American Water Works Manufacturers' Association will assume responsibility for the exhibit features as well as the entertainment program of the New England and also the Southwestern Water Works Association conventions, along the same lines as are now prevailing at the American Water Works Association conventions. In order to accomplish this and to meet the conditions prevailing in these two associations (namely, that they have associate members who are distinctly local in their character and not interested in the activities of any other association such as the American Water Works), the executive committee of the Manufacturers' Association have unanimously approved amendments to the constitution establishing a sectional membership, the purpose being to limit the activities of the sectional members to the one organization with which they are associated.

ALBERTA INDUSTRIAL CONGRESS

(Staff Correspondence)

THE opening session of the Alberta Industrial Congress, the first meeting of its kind in western Canada, was held August 13th, in Calgary. On the two preceding days the delegates had visited Medicine Hat and Lethbridge with a view to seeing the southern portion of the province. After spending two days in Calgary for the business meetings, they went to Edmonton on the 15th. The general impression gained by the delegates was that this is the beginning of a movement which will develop from year to year and awaken the people of Canada to the wonderful possibilities of the west, not only as regards agriculture, which is already recognized, but for industrial purposes. M. A. Brown, mayor of Medicine Hat, acted as chairman of the Congress.

The congress received several addresses of outstanding interest. Dr. A. B. Macallum, chairman of the Council for Scientific and Industrial Research, said that Alberta's coal supply would last only five thousand years with the present population or two thousand years with a population of twenty millions. Canada needed an organized institution that would direct the development of her natural resources. Eugene Coste said Alberta had the biggest oil fields in the world, 1,600 miles by 300 miles wide. A defense of government ownership of railways in its practical working was made by E. A. Warren, general manager of the Canadian National Railways.

Development of the West

A remarkable story of the industrial development of the west in general, and Alberta in particular, was told by J. E. Walsh, general manager of the Canadian Manufacturers' Association.

"Some idea of the development of manufacturing in western Canada," said Mr. Walsh, "is given in the table which has been compiled on this subject. This table goes as far as 1917, and does not show the increases of the last two years, which have been considerable. The figures for the three prairie provinces—Manitoba Saskatchewan and Alberta, are:—

Year.	No. of Establishments.	Capital.
1900	429	$ 9,229,561
1905	554	37,036,193
1910	902	84,479,837
1915	1,881	154,874,530
1917	4,082	197,475,107

"These figures show what a remarkable increase took place in the last two years accounted for. For the period between 1900 and 1917, the figures for the whole of Canada are: In 1900, number of establishments, 14,650, and capital $446,916,437. In 1917 there were, established 34,380 and capital $2,772,517,680."

"The Coal Areas in Alberta" was the subject of an address by D. B. Dowling. He traced the geological formation of the Alberta coal fields and mentioned the surface seam of anthracite in the Crow's Nest district, which is 135 feet thick. Because of its vast resources of soft coal Alberta is, he said, similar to Wales.

Alberta's Power Resources

James White, assistant to the chairman of the Commission of Conservation, dealt with "Power of Alberta—Water, Coal and Natural Gas." Referring to the development of power throughout the world, he stated that 75,000,000 horsepower had been developed, of which 29,000,000 is used in the United States, 13,000,000 in the United Kingdom and 6,000,000 in the British Dominion and dependencies. So far as water power is concerned, Calgary is more valuably situated than any other city in Alberta, the six powers on the Bow River having an aggregate minimum of 60,000 horse-power with regulated river and less than one-half of that amount with unregulated river. The Rocky Rapid power on the Northern Saskatchewan, which is sixty miles from Edmonton, would require the erection of a dam 85,000 feet

(Concluded on page 266)

NATIONAL INDUSTRIAL CONGRESS

FOLLOWING the meeting recently held in Ottawa by the labor sub-committee of the Reconstruction and Development Committee of the Cabinet, the Dominion government has announced that a national industrial conference will be held in Ottawa, beginning September 11th. Following is the agenda:—

(1) Consideration of the question of the desirability of unifying and co-ordinating the existing labor laws of the Dominion parliament and of the provincial legislatures, and the consideration of any new labor laws which are deemed necessary.

(2) Consideration of: (a) Employees' right to organize; (b) recognition of labor unions; (c) the right of employees to collective bargaining.

(3) Consideration of: (a) The recommendations of the Royal Commission on Industrial Relations in favor of the establishment of a bureau to promote the establishment and development of Joint Industrial Councils; (b) the further recommendations of the Royal Commission on Industrial Relations regarding the establishment of joint plant and industrial councils.

(4) Consideration of the recommendation of the Royal Commission on Industrial Relations respecting hours of labor.

(5) Consideration of minimum wage laws.

(6) Consideration of the recommendation of the Royal Commission on Industrial Relations that the findings of the commission be put into effect in all work controlled by the government where the principles of democratic management can be applied.

(7) Consideration of resolutions relating to any other features of the Royal Commission report.

(8) Consideration of the labor features of the Treaty of Peace.

(9) Consideration of any other proposals which may be introduced bearing on the relations of employers and employees.

In connection with the present industrial situation, Sir Robert Borden has issued the following statement:—

"As announced in the Governor-General's speech at prorogation, it is the intention of the government to summon, within a few weeks, a representative conference for the purpose of an intimate and friendly discussion of relations between employers and employed, and for consideration of the report of the industrial relations commission. The provincial governments will be invited to attend, and the various organizations of employers and employed will be requested to appoint representatives. It is hoped that such a conference will be productive of better understanding and a more thorough co-operation. Meantime, it is most important that actual working conditions should be fully realized by the Canadian people. For five years the world has been wasting the productive capacity of about 50,000,000 men actually engaged in warlike activities. The remainder of the producing population has been to a considerable extent occupied in producing munitions and instruments of destruction. Millions of men must now resume the normal activities of peace. The business of the world has been completely disorganized, and a long period will probably elapse before it can be completely re-established. After the present period of inflation has passed, Canada, in common with other countries, probably will face a period of depression.

"To meet the possible imminence of such conditions, the government has pledged the credit of the country to a very large extent in order to provide employment for the gallant men returning to our shores from war service, and for those engaged in war industries which now have ceased. Many employers of labor have undertaken work at little or no profit in order that their lines of industry might afford every possible opportunity for employment. Up to the present such employment has been fairly abundant, but this condition may not continue indefinitely. Efforts to provide employment will obviously be of little avail if the energy of the country is exhausted in lockouts or strikes occasioned by differences which ought to be settled by peaceful methods."

ENGINEERING INSTITUTE ELECTIONS

AT a meeting of the Engineering Institute of Canada, held August 19th in Montreal, the following elections and transfers were announced:—

Members.—T. J. Locke, Shelburne, N.S.; F. D. Reid, Cobalt, Ont.; Sven Svenningson, Montreal.

Associate members.—J. N. Anderson, Vancouver; C. L. Archibald, St. John, N.B.; G. W. Beresford, Ottawa; H. M. Bigwood, Victoria; R. E. Buckley, Niagara Falls, Ont.; M. A. Burbank, Winnipeg; W. R. Campbell, Campbellton, N.B.; W. B. Crombie, Niagara Falls, Ont.; F. M. Dawson, Westmount, P.Q.; C. H. Ellison, Firdale, Man.; C. C. Elliott. Brooks, Alta.; J. L. Franzen, Medicine Hat, Alta.; R. P. Freeman, Halifax; S. R. Frost, Niagara Falls, Ont.; L. L. Gisborne, Niagara Falls, Ont.; William Harland, Toronto; T. L. Hughson, Niagara Falls, Ont.; W. A. Janssen, Montreal; G. H. Lowry, Niagara Falls, Ont.; W. J. MacKenzie, Vancouver; J. G. MacLaurin, Sault Ste. Marie, Ont.; E. S Malloch, Ottawa; Norman Malloch, Niagara Falls, Ont.; J. B. McAndrew, St. Catharines, Ont.; Lyle McCoy, Montreal West, P.Q.; T. S. Mills, Ottawa; W. G. Montgomery, Peterboro, Ont.; R. C. Morgan, St. Catharines, Ont.; J. B. Petrie. Wabana, Nfld.; G. M. Ponton, Ottawa; O. W. Ross, St. Catharines, Ont.; H. R. Silcox, Toronto; Stewart Troop, Moncton, N.B.; R. S. Trowsdale, Calgary, Alta.; E. O. Way, Ottawa.

Juniors.—Claude Bradley, Calgary, Alta.; A. W. Crawford, Hamilton; D. B. Gardner, Toronto; N. G. McDonald, Niagara Falls, Ont.; C. S. MacLean, Halifax; W. B. Pennock, Ottawa; J. H. Ryan, Halifax; F. B. Young, St. John, N.B.

Associates.—J. F. Block, Calgary, Alta.

Transferred, associate members to members.—J. R. Cockburn, Toronto; G. H. Ferguson, Ottawa; J. F. Greene, Winnipeg; A. R. Holmes, Toronto; I. H. Nevitt, Toronto; H. R. Miles, Lethbridge, Alta.; G. K. McDougall, Montreal; D B. McLay, Vancouver; A. R. Sprenger, Montreal.

Transferred, juniors to associate members.—W. E. Blue, Ottawa; J. W. Ford, Niagara Falls, Ont.; M. H. French, Calgary, Alta.; F. I. C. Goodman, Halifax; A. W. Gregory, St. Stephen, N.B.; R. B. Harkness, Toronto; W. W. Hay, Rogers, Mich.; B. B. Hogarth, Ottawa; R. G. Lye, Toronto; J. A. MacGillivray, Winnipeg; R. C. MacLachlan, St. Catharines, Ont.; H. M. Morrow, Montreal; F. O'B. Nehin, Montreal; J. H. Norris, Montreal; J. B. Shaw, Victoria; J. C. Stewart, Ottawa; Norman Wilson, Ottawa.

Transferred, students to associate members.—J. E. Barcelo, Montreal; E. R. Marien, Quebec.

Transferred, students to juniors.—Theodore Dery, Rimouski, P.Q.; R. C. Ward, Toronto.

At Big Eddy, on the Spanish river, Algoma District, Ont., the International Nickel Co.'s conservation dam, now being constructed, will raise the level of the river 100 ft., and will create a lake with an area of 15 sq. mi. Combined with the storage in the upper third of the Spanish river watershed, it will increase the minimum flow to over 1,800 c.f.s., or almost three times the natural low-water flow.

The New South Wales government intends to proceed immediately with a scheme for a large hydro-electric development, says the weekly bulletin of the Department of Trade and Commerce of Canada. Complete plans have been prepared for two independent schemes, the estimated cost of which is about a million dollars. Of this amount it is expected that half will be spent during the next twelve months. Although there is an ample supply of water power at various points throughout the state, it has not previously been developed and all power at present is derived from coal. When the plans and specifications for the proposed schemes are ready, they will be forwarded to the Department of Trade and Commerce at Ottawa for the convenience of Canadian manufacturers who may wish to tender on some of the equipment.

ECONOMIES OF REINFORCED CONCRETE WALLS FOR UNCOVERED RESERVOIRS*

By H. E. Babbitt
Associate in Municipal and Sanitary Engineering, University of Illinois

IN the design of a reinforced concrete wall for an uncovered reservoir the choice of the type of wall is dependent mainly upon economy. The determination of the most economical wall for any particular conditions can be made by designing walls of various types to fulfill the conditions and making a detailed estimate of cost from these designs. Such designs have been made for walls varying in height from 5 to 30 ft., either with or without earth backing. The types of walls studied are shown in Figs. 1 to 6 inclusive. The least volume of concrete per foot of length of these walls for different heights is shown in Figs. 7 and 8. The relative economy of the different types of walls is indicated by the relative amount of concrete in the different types. The difference in the volume of concrete and therefore the economy of the "special" type of wall, compared with the cantilever wall, is striking.

Although the cost of reinforced concrete walls is not directly proportional to the volume of concrete, for any two walls of the same height and with the same loading, the relative cost is approximately as the volume of concrete. The amount of steel is approximately proportional to the volume of the wall. The cost of the form work is dependent more on the type of wall than upon the volume of concrete. Since the amount of form work on the "special" wall is somewhat greater than for the cantilever wall, the apparent saving by the use of the "special" type is somewhat reduced, but the relative economies of the different types is unaffected.

These designs were based on a factor of safety against overturning of 2. The working strength of steel was taken as 16,000 lbs. per sq. in., and of concrete as 650 lbs. per sq. in. No section less than 8 in. thick was used. The greatest intensity of foundation pressure was 6,000 lbs. per sq. ft. The "active" earth backing was assumed to act as a liquid weighing 20 lbs. per cu. ft. Although these assumptions may not be in accord with all conditions of design, a difference in the unit stresses, thicknesses, etc., will affect all types of wall alike and will not affect the relative economy.

In making the designs of these walls the relative economy of various details was developed. In the cantilever wall the economical length of the footing is shown in Fig. 9. For the buttress walls, the economical buttress spacing, the best details of the buttresses, and the effect on the volume of the wall by a change in the buttress spacing are shown in Figs. 10 and 11. Similar details are shown for the other

types of walls in Figs. 12 to 15.

In determining the volume of concrete in the walls the resisting moment against overturning of all portions of the wall was expressed in terms of as few unknown dimensions as possible. The resisting moment was equated to twice the overturning moment. When it was not possible to express the resisting moment in terms of only one dimension, all but one dimension were assumed and the unknown dimension solved from the equation. With all dimensions known the determination of the volume of the wall was a matter of solid geometry. New values of the assumed dimensions were tried until the least volume of concrete for the given height of the wall was found. It was in the process of such computations that the economical dimensions of the various details were found.

The expressions for the dimensions of various portions of the walls were determined either analytically or by trial in such a manner as to make possible the expression of the resisting moment in but few unknown terms. For certain details the economical dimension is that dimension which will give the least amount of material commensurate with the load which is to be supported. In other details the economical dimension is not a function of the load. Those dimensions which depend almost directly on the load were determined analytically, whereas those dimensions which are not direct functions of the load were determined by a method of trial. The following is a summary of the formulas for the details of all of the walls. In addition to the notation on the figures the ordinary notation used in reinforced concrete has been used except that S'_1 represents the effective depth of a beam and S_1 represents the actual depth.

$t_2 = h_2/15$ .....(27)
$t_1 = 0.67$ .....(28)
t_2, t_4 and t_3 determined graphically from Fig. 16.

The analytical expressions taken together with the graphical representations show the economical dimensions of every portion of the types of wall studied. The results show that for a wall with earth backing a buttress type is the cheapest unless the gain of the floor by the use of the "special" type is taken into account. For walls without earth backing the "special" type is the most economical, regardless of consideration of the saving in the floor area.

*The curves of Fig. 16 represent correct thickness of slab in accordance with the expression $t = bh^{1/2}/40$. Straight lines represent approximate solutions as used.

G. T. Milne, of Montreal, H.M. Senior Trade Commissioner for Canada and Newfoundland, is being transferred to Cuba as commercial secretary to the British legation in Havana.

RECOMMENDED PRACTICE OF MISSISSIPPI VALLEY STATE HIGHWAY DEPARTMENTS FOR CONCRETE ROAD CONSTRUCTION

AT a conference of the Mississippi Valley Association of State Highway Departments, held to consider questions relating to rural concrete road construction, the following "recommended practice" was adopted:—

Proportions.—One-course road: The concrete for a one-course pavement that is to be machine finished should be mixed in the following proportions: 1 sack of cement, 2 cu. ft. of sand and 4 cu. ft. of coarse aggregate. For work that is to be hand finished the proportions should be 1 sack of cement, 2 cu. ft. of fine aggregate and 3½ cu. ft. of coarse aggregate.

Two-course road: The proportions of the concrete for a two-course pavement should be as follows: For the lower course, 1 sack of cement, 2 cu. ft. of fine aggregate and 4 cu. ft. of coarse aggregate.

The proportions for the wearing course should be 1 sack of cement, 2 cu. ft. of fine aggregate and 3½ cu. ft. of the coarse aggregate prescribed for the wearing course of the two-course pavements.

Quantity of Water: It is recommended that extreme care be employed in proportioning the mixture as regards water content, and that this fact be checked by the slump test as follows: For the test, 6 by 12 in. cylinders should be tamped full of the concrete as mixed and the cylinder immediately removed. For work that is to be finished by hand, the slump of the concrete upon removing the cylinder should not exceed 6 in. and for work that is to be machine finished the slump should not exceed 2 in.

Thickness.—The thickness should be not less than 7 in. at the sides nor 8 in. at the centre for two-track roads up to 20 ft. in width. The thickness for single-track roads should be not less than 7 in. at any point.

Widths.—It is inadvisable to build concrete roads less than 18 ft. in width. Where a single-track road must be built it should be made 9 ft. in width and the 9 ft. should be centred on the centre line. Pavements with widths between 10 ft. and 16 ft. should not be built.

The width of grade to be traveled should be not less than 24 ft. for any width of pavement and the minimum over-all width of shoulders should be at least 8 ft. more than the pavement width.

Crown.—The crown should be a total of 1 in. for two-track roads not exceeding 20 ft. in width. If on centre line the crown for single-track roads should be ½ in. If placed with one edge on the centre line the surface should be sloped all one way with a total slope of 1 in.

Alignment.—No radius should be less than 200 ft. on centre line of turns.

Whitening Turns.—On all turns the centre line of the road should be marked by a white strip 8 in. wide.

Superelevation of Curves.—Except when drainage condition may prevent, the grade of the original centre line before widening is to be maintained where pavement is superelevated. The crown of the surface is to be flat where pavement is superelevated.

Grades.—Concrete pavements can be successfully constructed on any maximum grade likely to prove best from general economic consideration. In the middle west maximum grades exceeding 6 to 8% should not be adopted under ordinary circumstances.

Considering the permanency of concrete surfacing a greater expenditure of money is justified in eliminating frequent and minor breaks or changes in grade than is the case with a less permanent type of road.

Vertical curves on steep grades should be sufficiently long to give an unobstructed view of at least 250 ft.

Subgrade.—It is recommended that if possible the subgrade for a concrete pavement be not trenched out and that it be kept higher than the berms, so as to provide drainage directly to the side ditches.

Very careful attention should be given to the rolling of the subgrade. It is recommended that a macadam type of roller be used, weighing not less than 10 tons. If the rolling at any time causes the subgrade to become wavy, the rolling should be stopped immediately over the wavy parts, and the soft material investigated. In clays this is almost always due to moisture and unless it is possible for it to dry out by the sun and wind without delaying the work, it should be removed and replaced with dry clay or other suitable material that can be rolled in a satisfactory manner. If any depressions develop they should be filled with acceptable material as the rolling progresses. Sand and sandy soils require a minimum amount of rolling.

It is recommended that the rough grading be completed very closely to the intended cross section of the subgrade and to the full width of the shoulders. Avoid shallow filling without plowing. Avoid filling narrow, deep ruts without plowing and disking. The finished subgrade immediately ahead of the concrete should be corrected to proper cross section, using a template.

Where the method of depositing the aggregates on the subgrade is followed, the subgrade should be completed fully in sections not exceeding 600 ft. in length immediately before the aggregates are deposited. The surface should be brought to true cross section, using a template or other acceptable method. The roller should be kept in constant operation while the aggregate is being delivered. Any ruts or irregularities caused by the handling of the aggregates should be filled up and thoroughly tamped. Wherever possible, hauling over finished subgrade with teams or motor trucks should be avoided.

Where necessary, to avoid formation of an objectionable layer of dust, the subgrade should be sprinkled in advance of placing materials.

Mixer.—The mixer should be of a standard paving type having a capacity of at least 2-bag batch, commonly known as size No. 14.

The mixer should be equipped with a boom and bucket or some other mechanical device that will deliver concrete of a proper consistency, also with an automatic timing device and a device that will accurately measure the water for each batch.

Water Supply.—In addition to the general recommendation of the American Concrete Institute recommended practice, the water supply should be free from injurious substances, duplicate pumping machinery should be provided, booster pumps should be provided on long pipe lines, and in all pipe lines there should be provided unions at intervals not greater than 1,000 ft. Tees for supply water to the mixer and for sprinkling should be placed at intervals not greater than 100 ft.

Time of Mixing.—Materials should be mixed at least one minute after the entire batch is in the drum. The speed of the drum should be not less than 12 revolutions per minute.

Side Forms.—Steel side forms should be used and after the forms are set the joints should be inspected carefully, using a straight edge to insure proper horizontal and vertical alignment.

Placing Concrete.—The operation of depositing, spreading, and finishing the concrete should be as nearly continuous as possible for the full width and thickness of the pavement. When delays, of sufficient length to permit the concrete deposited to attain initial set, are necessary a suitable header should be placed at right angles to the road and the concrete finished to this header to true elevation and cross-section.

The concrete may be transported from the mixer to place on the subgrade in any convenient manner which avoids the segregation of materials. Any device or method of operation which tends to segregate the materials in such a manner that later operations do not completely eliminate such segregation should not be permitted.

Placing Concrete in Cold Weather.—Every effort should be made to arrange for closing concrete road work in the fall or on about such date as the weather bureau reports for the locality for the past ten years indicate the probability of temperatures materially below the freezing point. If circumstances necessitate continuing work for a short period after freezing weather is likely to occur, precautions should be observed which will insure positively that the concrete may not become frozen under the most extreme conditions of temperature for the period, as indicated by weather reports for the past ten years. Concrete should be protected absolutely from freezing by suitable means for at least seven days after placing.

Expansion Joints.—Expansion joints should be used only in specific cases, such as junctions between the pavement and other fixed objects.

Expansion joints when used should consist of either high grade wool felt or a fibrous material combined with a coal tar or asphalt compound. The filler should contain, by weight, not more than 8% of mineral matter and not less than 5% nor more than 25% of fibre.

Contraction Joints.—Contraction joints should not be used. Construction joints should be made at the end of each day's work or when mixing is stopped for any reason longer than one hour.

Reinforcement.—For pavements up to 18 ft. in width with good foundation the value of any practicable amount of reinforcement is questionable.

For pavements over 18 ft., and especially where foundations are not thoroughly satisfactory, reinforcements, mainly in a transverse direction, may be used to advantage.

Where reinforcement is used it should be wire mesh or separate bar reinforcement, not less than 40 lbs. per 100 sq. ft., and the proportion of transverse to longitudinal steel should be not less than 3 to 1.

The reinforcing should be placed not less than 2 in. from the finished surface of the pavement. Adjacent widths of the fabric should be lapped not less than 4 in. when the lap is made perpendicular to the centre line of the pavement and not less than 1 ft. when the lap is parallel to the centre line.

Machine Finish.—When mixtures of relatively dry consistency are used, such as those necessary to secure maximum strength as far as such strength is determined by the water content, mechanical strikers and tampers should be used. Machines should be so constructed and operated that they strike off and thoroughly tamp the concrete. They should be so constructed that they may be readily operated over the same area repeatedly. Machines to serve the purposes above indicated should be subject to the approval of the engineer. The mechanical device or devices used should be so made and operated as to leave the finished slab true to grade, crown, and surface and absolutely free from porous places.

Hand Tamping.—If a mechanical finisher is not used and the consistency of the concrete is to be as above described, after spreading the concrete should be thoroughly hand tamped by means of a tamper of the nature of a strike board operated by one or two men stationed at each end of the tamper on opposite sides of the roadway. Hand tamping should be vigorous and sufficient to consolidate the concrete in such a manner as to close all voids. The hand tamper should be followed by a final strike board and all operations carried on in such a manner as to leave the surface behind the final strike board true to grade, crown, and surface, and absolutely free from porous places.

Roller and Belt Finish.—If a medium consistency is used, the concrete should be spread, agitated, and tamped in such a manner as to insure positively the avoidance of stone pockets or porous places. It should be struck off true to grade, crown, and surface. It should then be rolled by a light hand roller of approved design operated in such a manner as to remove the surplus water and leave the surface true to grade and crown.

When hand methods of striking and tamping are used the final finishing should be executed by means of an approved belt operated in such a manner as to leave the pavement true to crown and free from waves, ridges, depressions, or other irregularities and with a uniform mat surface.

Curing.—As soon after finishing as may be possible, without marring the surface, the slab should be covered with

canvas. When the concrete has set sufficiently to obviate the possibility of marring, and where local conditions permit, suitable longitudinal and transvere dikes should be built and water supplied to cover the surface of the concrete to a uniform depth of 2 in. The water should be maintained on the surface for not less than 14 days. Under conditions where it is impractical to adopt the ponding method of curing, the surface of the concrete should be covered with not less than 2 in. of earth and kept moist for at least 14 days by wetting not less frequently than intervals of 12 hours.

Traffic should not be permitted to use the pavement in less than 21 days if the pavement has been subject to favorable curing conditions; nor in less than 40 days if subject to unfavorable curing conditions.

Traffic should not be permitted to use the pavement for a period of at least three days after removal of the water or earth covering.

MOOSE JAW WATER SUPPLY*

Commissioner Mackie Favors Plan for a 24-inch Continuous Wood Stave Pipe Line from Caron Head Works to the Saskatchewan River at a Cost of $1,630,000

AT a recent meeting held in Moose Jaw, Sask., at which representatives of nearly every Moose Jaw organization were present, steps were taken and a committee was appointed to take up immediately the question of the Saskatchewan River water scheme for Moose Jaw, as outlined by City Engineer G. D. Mackie, which, in the unanimous opinion of the meeting, was the only solution for the water problem that now exists.

Commissioner Mackie, although he mentioned several alternatives in his address, favored, for financial reasons, the plan for a 24 in. continuous wood stave pipe line from the Caron head-works to the Saskatchewan River, a distance of between 54 and 70 miles, depending on the route selected, which can be constructed and in operation, if started at once, by the end of this year, at an outside cost of $1,630,000, with an effect on the mill rate of from 5 to 7 mills, depending on the city assessment, if the city pays the entire cost, or of one mill only if it is found possible to secure aid from other sources as suggested.

Committee Appointed

The meeting, which was called under the auspices of the Board of Trade, at the suggestion of President George A. Maybee, resolved itself into a Citizens' Committee, with Mayor Hamilton as chairman. Mr. Mackie was then called upon to make his address, and following that, a short discussion which occurred was brought to a close by a motion stated by William Grayson and seconded by George C. Ingram, that the men named below be appointed a committee to go immediately into the engineering, financial and legislative problems that surround the scheme, and report back to a meeting of citizens to be held in the near future.

Mr. Grayson named the following members of the committee: Mayor S. A. Hamilton, City Engineer Commissioner G. D. Mackie, Alderman W. G. Ross and W. D. McIntyre, President George A. Maybee of the Board of Trade, Arthur Hitchcock, John H. Grayson, ex-Mayor W. W. Davidson, W. Gardner and W. E. Stephenson of the Moose Jaw Trades and Labor Council Executive.

Present Supply

Mr. Mackie, in discussing the water situation, dealt with the present water supply of the city, pointing out the fact that the maximum summer flow is now one million gallons per day, and that the maximum winter flow varies from 800,000 gals. per day to as low as 700,000 gals. per day. The average consumption per head per day in 20 cities of Alberta is 74.5 gals. In ten Saskatchewan towns the average is 47.9 gals. per head per day, and in the Dominion, as a whole, it is 111 gals. per head per day. Moose Jaw's average consumption per head per day is 53 gals.

In dealing with the industrial water consumption of the city, Mr. Mackie stated that in Moose Jaw the industries consumed more water than those in any other city in the province, and that in the months of January, February and March of this year one firm alone consumed 300,000 to 350,000 gals. per day. The water situation as a whole, he said, was that the city had a possible maximum supply of one million gallons per day, and that the average consumption in 1918 was 883,000 gals. per day, and that the industrial consumption had increased from 150,000 gals. per day in 1914, to an average of between 300,000 and 350,000 gals. per day.

High Cost Per Capita

Dealing with the cost of Moose Jaw's water system, the commissioner said that Moose Jaw's water system, if carried out as per his proposed scheme, would be the most expensive per head in the Dominion. To date, the total expenditure on the city's water system is $67.65 per capita. The expenditure to date per head in the Greater Winnipeg water area is $106.63, and Moose Jaw's, if the Saskatchewan River line is built, will be $149.15 per head.

Referring to a previous meeting at which he made the statement that there was sufficient water in Moose Jaw Creek to supply the city's needs for several years to come, Mr. Mackie said that he could only repeat that statement. The average run-off of the creek per year for eight years is seven and one-half billion gallons. Were that scheme gone ahead with, it would be necessary to built a ten billion gallon reservoir, which would hold enough water to supply the present population for three years. The land that would be flooded by such a reservoir would be five thousand acres, and the minimum estimated cost would be $1,250,000, of which amount $450,000 would be required for the pipe line alone. Of that sum $400,000 would have to be spent in the east end of the city, because of the fact that there is not at present any water main system there to connect with the mains large enough to start the distribution within the city of such a large amount of water. In addition, another disadvantage of this proposal is that if the city outgrows the supply that can be secured from the Moose Jaw Creek, the expenditure entailed in construction will be lost, because the next scheme possible of consideration is the Saskatchewan River. If the cost is at all comparable, there is no doubt that the Saskatchewan River scheme is the better of the two.

Mr. Mackie then considered the Saskatchewan River as a source of water supply for Moose Jaw. Mr. Francis, who was the engineer in charge of the Caron water works construction, and who recommended the Caron scheme over the Moose Jaw Creek, although admitting that it was only a tentative solution, did recommended Caron, because it was a distance of 20 miles gained toward the then considered ultimate solution, the Saskatchewan River, while the Moose Jaw did not offer that advantage. Mr. Francis, however, estimated on the Saskatchewan River scheme, and his figure was five million dollars.

Other Schemes Very Costly

Various Dominion government schemes are estimated at between eight and fifteen million dollars. Major McPherson, who proposed to build an open ditch carrying water from Pelican Lake, and through Thunder Creek, estimated his project at $850,000, but the disadvantages of his scheme were that the city would have such a supply available for but seven or eight months of the year, and that in order to secure a million gallons per day it would be necessary to pump between ten and twelve million gallons to take care of evaporation and percolation over the 60-mile open ditch. A flow of but one foot every two seconds could be secured.

Local Supply is Limited

It is possible by further development to augment the city's present supply locally, but the outside estimate made by Mr. Mackie is that 150,000 gallons per day could be thus secured, which amount, in his opinion, is not worth considering. With the stock yards in operation, they with the packing house and the C. P. R. could be expected to consume from

*From the "Western Canada Contractor."

one-half to three-quarters of a million gallons per day next winter.

His Saskatchewan River scheme, he said, included pumping at the river of all the water through a pressure pipe to the height of land, a height of 330 feet, into a two million gallon reservoir, and from there to the Caron headworks through a 24-inch continuous wooden stave pipe line.

Sixty-Mile Pipe Line

The shortest route from Caron to the river is 54 miles and the longest route considered is 70 miles. The short route cannot be used, however, owing to the fact that high ground intervenes between the river and Caron. In Mr. Mackie's opinion it will be necessary to build a pipe line of 60 to 62 miles to get the gravity flow from the height of land at the river to Caron. A survey would have to be made to determine the best route, as every mile of pipe line saved means a saving of $17,000.

In determining the size of pipe to be used for his scheme, Mr. Mackie stated that he started with the consideration of four million gallons per day capacity, an amount larger than the present needs. He therefore proposes a pump at the river sufficient only for the present needs, and to keep the cost as low as possible, has not provided for stand-by pump in the event of break down. This means that it could be figured that the pump at the river would have to be shut down two days per month because of accident, during which time the Caron system would be in a position to supply the city's wants. No filters would be used, it being planned to use the same type of infiltration gallery as in use at Battleford and North Battleford.

Wood-Stave Pipe Cheapest

"The cost of the auxiliaries to such a scheme," said Mr. Mackie, "is mere bagatelle to the cost of the pipe line. There has been a great deal of discussion here on wooden pipe lines, but I intend to advocate a wooden pipe line for financial reasons." He then quoted figures showing that the cost of 24-inch wooden pipe laid in the ground, exclusive of the cost of excavation and back-filling is $2.30 per foot, of steel $5.74 per foot, and cast-iron $10.51 per foot. The cost therefore for 70 miles of wooden pipe would be $850,000; for steel, $2,123,000; and for cast-iron, $3,890,000. In addition there would be a tremendous saving in the tonnage hauling cost, the wood tonnage being about 9,000 tons, steel 15,000 tons, and the cast-iron the heaviest, about 45,000 tons.

The outside cost of the entire scheme for the three types of pipe, wood, steel and cast-iron, were quoted by Mr. Mackie as follows: Wood, $1,630,000; steel, $2,900,000; iron, $5,000,000.

Figuring the life of the wooden pipe line at but fifteen years, he said the saving on the carrying charges would be some $60,000 per year, which would amount in fifteen years to a sum sufficient to enable the city to replace the wooden pipe line.

Total Cost $1,630,000

The cost of the system with 24-inch wood pipe, would be as follows:—

Diesel engine and pump at river	$ 148,000..
Force pipe to height of land, 330 ft.	65,000
2 million gallon reservoir at river	65,000
Pipe line laid	1,184,925
Damages	88,630
Engineering and contingencies	78,445
Total	$1,630,000

In further describing the type of pipe line recommended, Mr. Mackie declared that it is different from the old type in that it is of the continuous stave type, thus avoiding joints and the leakage which occurred and always will occur in such joints. In addition, the bands of the pipe, instead of being continuous, are individual, so that when one break occurs the whole pipe will not leak, as in the case of the Snowdy Spring line, for instance. He would lay the pipe but 6 feet in the ground, sufficient only to protect it from rodents, etc., and to keep it below ground. That depth is sufficient to protect from frost at the velocity the water would travel through it. The El Paso Railway was faced with a similar situation for water, he said, and decided on wood because of the prohibitive cost of iron or steel. They now have 116 miles of this pipe in operation, and it is giving satisfaction.

The present Caron line has a capacity for 2,400,000 gals. per day. This can be increased to a maximum of 3,960,000 gals. per day, by different placing of pumps, and different methods of taking water from new to old pipe line, either through Caron reservoir, or direct to the old pipe line. The minimum winter flow of the Saskatchewan River at Saskatoon is 600 million gals. per day.

The Financial Problem

In conclusion, Mr. Mackie dealt with the financial aspect of the scheme, saying that while it did not present any engineering difficulties, it does present financial difficulties.

He presupposes the issue of 20-year debentures, assuming that the life of the wooden pipe is fifteen years. In the life of the pipe he plans to set aside a sum of $400,000, which, after the debentures had been retired, could be used as a nest egg for the replacing of the line. The carrying charges on this basis, at 5½% would be as follows: Interest charges, $89,000 per year; sinking fund payments, $54,000, and depreciation, $20,000 per year; a total of $163,000 per year, which, added to the carrying charges of the present water works, would make the carrying charges for the entire system $318,000 per year. Figuring on the sale of half a million gallons per day more water than at present, the annual deficit on water would be $146,000 per year, which on the present assessment would cost the citizens 7 mills additional tax rate.

On the 1913 assessment, he said, this could be handled by 3 mills additional levy.

Mr. Mackie next dealt with the city's borrowing power, which at the present time is $400,000 in round figures. His suggestions for increasing it to bring down the mill rate necessary to handle the water system proposed were several. One method was by increasing the improvement assessment to 60% instead of the present 45%. Another was to revert to the old business tax assessment instead of the present business license. A third was to increase the present land assessment by four million dollars. All three of these suggestions, if adopted, would bring the city assessment up to $31,000,000 and would make it possible to carry the proposed and present water systems for 5 mills instead of 7 mills.

The Canadian Board of Commerce has now been constituted and will shortly be available for such complaints as may be laid before it. It will act under the Combines and Fair Prices Act, and is given power to institute investigations on its own motion or at the request of any responsible parties who bring subjects to its notice. The chairman states that the procedure will be of an informal character.

Perhaps the largest reforestation scheme ever undertaken in Canada is being carried out in Quebec this year. The Laurentide Co., of Grand'mère, is planting over 1,000,000 seedlings, mostly Norway spruce, with some white Scotch and jack pine and balsam. The Riordon Co., of St. Jovite, is also planting about 750,000 seedlings. Much the greater number of the seedlings used are imported from forest nurseries in the United States.

In a recent address before members of the Advertising Club, of Baltimore, Md., H. D. Hubbard, of Washington, D.C., secretary to the U.S. Government Bureau of Standards, made an earnest plea for the adoption of metric units of measurement in the United States and Canada. Mr. Hubbard pointed out that during the war many United States and Canadian manufacturers were forced to use the metric system in the manufacture of guns and other ordnance, and two principal works had to use it in the building of locomotives. If the work on the blue prints for these locomotives had to be done in feet and inches, Mr. Hubbard said, the locomotives would never have been built on this continent. He further said that by refusing to adopt the metric units, United States and Canada are as far behind in the matter of proper standards as was China, but that China has now adopted the metric system.

STRESSES IN CONCRETE ROAD SLABS FROM WHEELS OF HEAVY TRUCKS

At the present time it is impossible to calculate the proper thickness of a concrete road slab with much certainty. It is known that a thicker slab is required where the subgrade is soft than where it offers a good bearing, and that heavy loads require a thicker supporting slab than light loads; how much thicker, however, has not been determined. The stress in a slab depends upon the bending moment produced in the slab, and this in turn is dependent largely upon the distribution of pressure over the subgrade. It is recognized that ununiform subgrade pressures are due to causes other than the heavy traffic loads carried by the slabs. An investigation to discover how the road slab is stressed directly under the wheels of heavy trucks and to determine whether this stress is apt to be a governing influence in the design of the slab, has been initiated by the United States Bureau of Public Roads. This test is one of a series of investigations outlined to include an adequate range of the different varieties of subgrades and slab thicknesses. The test was made on the concrete road between Camp Humphreys and Alexandria, Va. The road surfacing at this point is 18 ft. wide, 8 in. thick at the centre, and 6 in. at the sides. A 1:1½:3 gravel concrete was used, having a crushing strength, as determined by 6 by 12 in. cylinders cast in the field at the time the road was laid, of 3,190 lb. per sq. in. The aggregates in the concrete at this point were Potomac River sand and gravel. Here the road runs through a 6-ft. cut and the subgrade in the past has remained rather wet and soft. The soil is composed of a sticky clay, which, when wet, has very low bearing value.

Designed Special Pressure Cells

To measure the pressure distribution, four pressure cells were designed in the Bureau of Public Roads. In order to determine the distribution of pressures under heavy wheel concentrations, a class B standard army truck was loaded with 5 tons of sand. The front wheels and rear wheel of the loaded truck were weighed separately and the axle loads were found to be 5,000 lbs. and 17,000 lbs., respectively.

On February 5th, 1919, a test was made on the Camp Humphreys road with this loaded truck. It was backed 1 ft. at a time up to the central measuring cells. When the rear wheels reached a position directly over the cells, the truck was backed 1 ft. at a time still farther until the front wheels were just over the cells. As a second test the truck was backed with the wheels as close to the side of the road as possible so that they would be made to come directly over the cell placed at the extreme side of the road. During the progress of the preliminary measurements, taken over a period of four months, opportunities offered themselves for obtaining some idea of the effect of light loads on the subgrade pressures, and these are presented in the following table:—

		Ford.	Boiler.	Front army truck.	Rear army truck.
Load on slab ...	[1]200	[1]350	[1]3,680	[1]2,500	[1]8,500
Maximum intensity of pressure	[2]0.2	[2]0.4	[2]3.5	[2]1	[2]6.5
Radius of area of distribution	..	[3]2	[3]5½	[3]3	[3]6

[1]Pounds. [2]Pounds per square inch. [3]Feet.

Summarized Results of Investigation

The results of the investigation are given by A. T. Goldbeck, engineer of tests, U.S. Bureau of Roads, in a report made public recently by the Bureau. The tentative conclusions drawn from this preliminary investigation are as follows:—

1. That a concrete road slab under the action of traffic or perhaps under the influence of frost and different percentages of moisture in the subgrade is continually bending, so that the reaction pressures between the subgrade and slab are neither constant nor uniform in intensity.

2. The reaction pressures due to heavy wheel loads are a maximum directly under the loads and vanish to zero in a comparatively small radius, which partially depends upon the intensity of the load. A heavy wheel load is distributed over a larger radius than a light wheel load. For this particular subgrade, a load of 8,500 lbs. has a radius of distribution of pressure of about 6 ft., most of the pressure, however, being exerted over a radius of about 4 ft.

3. As the concrete slab recovers from its deflection after the passage of a load more readily than the soft subgrade, there is a tendency for the continual deflection of the slab to produce areas having very little or no bearing. If the traffic is concentrated at the centre of the road, as it is on many concrete roads, the continual deflection tends to depress a soft subgrade away from the centre of the slab, which would then be more largely supported at its sides. In extreme instances this might account for some longitudinal cracking in concrete roads.

4. As nearly as can be estimated from the results of this test, the tensile stress in an 8-in. concrete slab directly under an 8,500 lb. wheel load at rest on the road is only 34 lbs. per square inch when the slab is well supported on the subgrade. As the modulus of rupture of 1:1½:3 concrete is about 600 lbs. per square inch, it is seen that this pavement should be able to withstand considerable impact before cracking. Should the concrete arch, over very soft spots, so that there is no support directly under the load, the tensile stress may become very high. Such a condition arises when the sides of the slab are raised by frost action or possibly when the subgrade is worked away from under the slab by continual deflection.

5. It is probable that the tensile stress which results in the slab directly under heavy wheel loads is never very great as long as the slab rests on the subgrade and it is unlikely that the slab design would ever be controlled by this stress.

ONTARIO HYDRO ASKS COMPENSATION

Formal application has been made to the Minister of Finance by the Hydro-Electric Power Commission of Ontario, asking that the Dominion government reimburse it approximately $5,000,000 for the extraordinary war expenditures incurred on unavoidable extensions due to the necessity of providing power on a large scale for the manufacture of munitions and other materials for war purposes in order to meet the demands made by the manufacturers and the power controller. In support of this application the commission has forwarded to Sir Henry Drayton a file containing the voluminous correspondence and orders covering the period when the extensions were made. It is pointed out by the commission that the power controller, under whose orders much of this work had to be undertaken to meet the needs of the munitions manufacturers, had authority only over Ontario. This control was exercised, it is claimed, almost solely over the Hydro-Electric Commission. In such cases as private companies ordered to make extensions, it is said by Sir Adam Beck that they were either reimbursed by the Imperial Munitions Board or the manufacturers whom they supplied.

In making this application to the Dominion government the commission states its belief that the Dominion government will recognize that the financial burden of the war should be borne by the people of the Dominion as a whole, and not by one province or group of municipalities who happened to be in the fortunate position, owing to the existence of cheap hydro-electric power, of contributing so largely to the defence of the Empire by the manufacture of these munitions.

The items in the Commission's bill, which is for $4,902,000, are as follows: $2,500,000 for the extension to the Ontario Power Co.'s plant, which was temporary for war purposes only and will soon be abandoned; $652,000 for duty on equipment for the O.P.C. extension and the Queenston-Chippawa development; and $1,750,000 for increase in cost, compared with normal times, of extensions of transmission lines and equipment on the Niagara system necessitated by the power requirements of the munition manufacturers. Sir Adam Beck points out that in the United States the government has compensated power companies for extraordinary war expenditures.

MODERN MACHINERY SUPERSEDING LABOR

POWER-DRIVEN machinery is being manufactured with ever-increasing capacities, reducing labor costs (in hours, at least, if not always in dollars, owing to increasing wages) per unit of work done, permitting larger jobs to be completed within the same time, reducing the important item of "interest during construction," and providing the engineer with more powerful weapons with which to overcome obstacles and to harness the forces of nature.

A striking example of the utility of big plant for big work, is the Queenston-Chippawa power canal, the progress of which is described in this issue. The amount of earth and rock being handled by a comparatively small force, constitutes a record previously unknown in the construction world. The daily removal of over 20,000 cu. yds. of earth and rock, in addition to the accomplishment of a great amount of other work such as railroad construction, bridge-building, etc., all with an average daily payroll of considerably less than 2,000 men, is a feat that could not have been performed a few years ago without expenditures for plant that would have been enormously out of proportion to the value of the work being done. This feat has been made possible by the development of economical machines that are giants in comparison with the machines of a decade ago.

The construction undertakings of the past were not large enough, with but few exceptions, to permit of huge investments in construction plant, and in many cases where unusually powerful equipment could have been used, it was not designed owing to the recognized impossibility of finding a market for it after the work had been completed. To-day there is almost invariably a market for all construction equipment that is in good condition, regardless of its size.

The power-shovel manufacturers and the builders of large crushers are, in a great measure, responsible for the improved methods of handling rock, and they predict that within a very short time they will be selling 10-yd. shovels, 84-in. by 120-in. jaw crushers and 84-in. gyratory crushers. On the Queenston-Chippawa job there are 8-yd. shovels and a 60-in. by 84-in. jaw crusher. Since this job was started, 66-in. by 86-in. jaw crushers and 60-in. gyratory crushers have been built and placed in successful operation.

The evolution of huge shovels and crushers has been slow but steady and sure. Sizes of crushers built thirty years ago, and at that time considered large, to-day are not manufactured excepting for laboratory work, as their operation is no longer economical.

ARE YOU AN UNRESPONSIVE CITIZEN?

ONE of the greatest statesmen in the United States, whose name, it is said, cannot be disclosed, recently made the following statement concerning the activities of the United States Engineering Council:—

"Your task is appalling. You have been elected to lead engineers into a political reform. They are the most unresponsive citizens that we have. Your organization has a praiseworthy purpose, but if it were sponsored by almost any other group of reputable men than engineers there would be more promise of success. If your organization succeeds, I believe you will find that it will not be the engineers who have carried through. Their aloofness and indifference in all matters outside of their own professional sphere, are among the unexplainable things in our political life."

This statement, we consider, is a totally unmerited condemnation of engineers as public-spirited citizens. They are not "unresponsive citizens." To the contrary, they are among the hardest-working, most unselfish, modest members of society. Because they do not toot their own horns like professional politicians, those politicians, it seems, are prone to consider them "unresponsive." Had the statesman substituted the words "self-effacing" for the word "unresponsive," his summing-up of the situation would have been far more accurate and truthful—all but the last sentence. The last sentence should read:—

"Their hesitation in participating in matters outside of their own professional sphere is explained by the conditions now existing in our political life, whereby lawyers in high places appoint fellow lawyers to all positions of trust and prominence, almost wholly regardless of the special technical knowledge required for a proper fulfillment of the duties of those positions."

But perhaps the statement doesn't warrant our getting agitated. It is an anonymous statement. The man who made it should sign it and stand behind it, otherwise it must be classed with anonymous letters. The American Association of Engineers has forwarded a circular to all of its members calling their attention to this statement, and apparently attaching great importance to it. The inference made by the association's circular, in describing the statesman as "one of the greatest," is that President Wilson made the statement, because in Washington there is an unwritten law among newspaper men and others that the president must not ever be directly quoted. This rule does not apply to any other statesman. The inference that can thus be taken is undoubtedly unjust to President Wilson, because that great statesman has better sense and a keener insight into all professions than to make the mistake of interpreting the engineer's retiring disposition as indifference or unresponsiveness to the call of public duty, wherever or whenever it may be heard.

The Asphalt Association has decided to open an office in Toronto, and has appointed Capt. Bruce Aldrich as district engineer. Capt. Aldrich has resigned as deputy works commissioner of Baltimore, Md., where he had seven asphalt plants under his jurisdiction. He organized and equipped the municipal laboratory at Baltimore, and supervised the construction of more than 3,000,000 sq. yds. of sheet asphalt and bituminous concrete.

PERSONALS

CAPT. RAY FRASER ARMSTRONG has been elected town manager of Woodstock, N.B., the first town in New Brunswick to adopt this form of municipal government. Capt. Armstrong is a son of R. E. Armstrong, formerly editor of St. Andrew's Beacon. Capt. Armstrong is a graduate of the University of New Brunswick, where he earned the B. Sc. degree, and a post-graduate in engineering of McGill University. He has been an associate member of the Engineering Institute of Canada since April, 1915. Before the war, he served in various engineering capacities in Montreal, Edmonton, Banff, Tofield, Coronation, Vancouver and St. John. He was engineer-superintendent of water works and sewerage at St. John, N.B., when he enlisted in 1916. In France he was transferred to the Canadian Engineers and won his captaincy and the Military Cross in the last big drive.

LT.-COL. H. R. LORDLY, consulting engineer, of Montreal, has been elected a fellow of the Society of Engineers, London, Eng. Col. Lordly is a graduate of Cornell University and holder of the Fuertes medal. He took the 5th Pioneer Battalion overseas in 1916, and also served at the front with the Imperial army. The Society of Engineers is an amalgamation of the former Society of Engineers, established in 1854, and the Civil and Mechanical Engineers' Society, founded 1859. The merger took place in 1910. Under the new charter the membership is limited to one thousand.

ALBERTA INDUSTRIAL CONGRESS

(Continued from page 256)

high. The Baptiste power, 170 miles from Edmonton, might be developed to the extent of 12,000 horse-power, and another site on the Baptiste River would yield 6,000 horse-power. There are numerous other sources but they are for the present too remote to be of practical value.

Water, said Mr. White, is, however, only one source of power and the prevailing impression that it is cheaper than steam power is correct only under certain conditions. Compared with steam power it has the following advantages:—

(1) Cost of operation is usually much lower.

(2) Very few attendants are required in the plant and no fuel is required excepting for heating the building.

On the other hand there are the following disadvantages:—

(1) Usually the cost of development and installation is much higher than with steam power.

(2) The situation of the water power plant is fixed by nature and as a rule a transmission line is required to transmit the electric energy to the user.

(3) The service is less reliable owing to the possibility of (a) injury to the transmission line and (b) lack of power due to unusually low water.

During recent years, owing largely to the introduction of the steam turbine, the capital cost of modern steam plants and of many hydro-electric power developments are coming closer together and some engineers predict that at an early date steam-electric power will be produced at less expense, other things being equal, than hydro-electric energy. Alberta, he said, contains 87 per cent. of the coal in Canada and is, therefore, in an excellent position to produce steam power.

Plea for Scientific Development

Dr. R. D. MacLaurin, professor of chemistry in the University of Saskatchewan, spoke on "A Field for Reconstruction." "During the past five years," he said, "Canada's national debt has rapidly increased until it has reached the sum of $1,950,000,000, incurring interest charges to the amount of $115,000,000. Our adverse balance of trade with the United States in 1918 amounted to $292,000,000, and our exchange rate is 5⅛ per cent. The recommendation by the finance minister of Canada to meet that situation was 'increased production and thrift.' The war made it necessary for Canada to mortgage her resources, human and material, for the purpose of carrying on. The obligations were loyally and willingly assumed, but we are now confronted with the question—How is the liability to be financed? Will 'increased production and thrift' accomplish this?

"For the successful carrying out of a policy formulated for the development of our natural resources, the co-operation of men of scientific attainments is essential. In 1916, in urging the development of our resources, I suggested that provision be made in the case of a research subsidized by the government and leading to a discovery, invention or the improvement of a technical process, protecting the author in the ownership thereof. As government aid had, at least, materially contributed to such discovery, invention or improvement of a technical process, provision should also be made for a royalty to the government on its use for the purpose of maintaining a national research fund.

"The creation by the Alberta government of a ministry of industry, and the calling of this industrial congress by the Industrial Development Association of Alberta, is an outstanding recognition of the value of Alberta's natural resources, and a realization of the urgency for their immediate development.

"The Dominion of Canada ranks second among the nations of the world as regards its potential coal resources, which have been estimated at 1,234,269 million tons, of which 1,059,927 million tons, or 86 per cent. of the total, is possessed by the province of Alberta. Furthermore, the total coal in Great Britain and Ireland, Australia, India, South Africa, New Zealand, Rhodesia, Newfoundland, South Nigeria, British New Borneo, has been estimated at 494,961 million tons; consequently, according to the above figures, Alberta contains more than twice as much coal as Great Britain and her other possessions within the empire."

The speaker then showed how coal had contributed to the industrial development of England, Germany and other countries.

War Interfered with Progress

The closing sessions of the Congress were held in Edmonton on August 15th. The delegates were entertained at a banquet in the Macdonald Hotel given by the Board of Trade, at which A. M. Frith, first vice-president, presided. Short addresses of welcome were given by Mayor Clarke and James Ramsay, M.L.A. An address by Dr. John A. Allen on the mineral resources of Alberta was interesting and instructive. He pointed out that the mineral resources of the province stood second in the matter of basic wealth, the first place going to agriculture. The last few years had seen great strides toward the development of natural resources of Alberta, he asserted, the value of production in 1917 being computed at $16,000,000, and in 1918, $24,000,000. He considered, however, that the vast wealth was yet unknown, and that the north must be looked to for the full determination of the metallic wealth of the west. Here the indications were most favorable. The clay products were so extensive that it has not been possible to develop them. The war caused some hindrance in the matter of production in this regard, for while the value of the products produced in the province in 1912 amounted to one and a half million dollars, at the end of 1917 the output had decreased to half a million.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

BRIDGES, ROADS AND STREETS

Beloeil, Que.—Tenders will be received until 5 p.m., September 8th, by the town council, for reconstruction of macadamized roads. A. M. Cormier, secretary-treasurer.

Boston Creek, Ont.—The provincial government contemplates construction of roads through the Boston Creek mining district to the Skead area.

Brandon, Man.—The city council contemplates construction of the following macadam pavements, including intersections: Eighteenth St., Rosser to Victoria Ave., 42 ft. wide. Estimated cost, $12,755. Princess Ave., First to Sixth St., 42 ft. wide. Estimated cost, $8,254. Princess Ave., Fourteenth to Eighteenth St., 42 ft. wide. Estimated cost, $6,350.30. First St., Rosser to Victoria Ave., two pavements each 19 ft. 6 in. wide. Estimated cost, $12,020.80. Harry Brown, city clerk.

Brandon, Man.—The public parks board contemplate construction of the following works: Boulevard and curb on Princess Ave., both sides, First to Sixth St., length, 2,540 ft. Estimated cost, $2,794, and both sides from Fourteenth to Eighteenth St., length, 1,590 ft. Estimated cost, $1,749. Six foot boulevard and curb on Eighteenth St., Rosser to Victoria Ave., both sides, length, 4,304 ft. Estimated cost, $4,949. Twelve-foot boulevard and curb on First St., Louise to Victoria Ave., both sides, length 1,000 ft. Estimated cost, $2,000. Harry Brown, secretary.

Chatham, Ont.—Tenders will be received until noon, August 30th, by the Chatham township council, for construction of a steel and concrete bridge over the Little Bear Creek drain at the Lindsay Rd. Plans, etc., may be seen at the office of W. G. McGeorge, engineer, Chatham. L. A. Pardo, county roads superintendent, Chatham.

Como East, Que.—Tenders will be received until 6 p.m., September 8th, by the municipal council, for construction of roads. W. Sanderson, secretary-treasurer.

Elmira, Ont.—Construction of the local section of the provincial highway has commenced. This road is being poured in concrete, 16 ft. in width. It is expected that other stretches of concrete highway will be commenced near here in the near future.

Hamilton, Ont.—Plans and estimates are being prepared by the city engineer's department for construction of steps up the mountain on Sherman Ave. E. R. Grey, city engineer.

Haney, B.C.—Tenders will be received until noon, August 30th, by the department of public works, Victoria, B.C., for construction of a bridge on the River road. Plans, etc., offices of district engineer, court house, Vancouver, and at Parliament buildings, Victoria, B.C. A. E. Foreman, engineer.

Islington, Ont.—The Etobicoke township council has awarded contract to the Law Co., Toronto, for construction of 2.75 miles of macadam roadway on Queen St. from Lake Shore Rd. to Kipling Ave. Contract price, $22,200.

Kitchener, Ont.—City council contemplates widening street and constructing a subway on King St., under the G.T. Ry.

Lindsay, Ont.—The county good roads board intend to rebuild the road from the hospital westerly through Mariposa. Estimated cost $10,000 per mile. It was also decided to extend the pavement on Lindsay St. south from the swing bridge to the southern boundary of the Riverside cemetery. B. L. McLean, mayor.

Niagara Falls, Ont.—City council will construct pavement and curb on Benson St., from Victoria to St. Lawrence St.

Niagara Falls, Ont.—City engineer's estimates for pavement consisting of 2 ins. Willite on a 5-in. concrete base for Palmer St., between Benson and Victoria, is $3.35 per sq. yd. Total cost, $43,353.

Ottawa, Ont.—Contracts have been awarded by the department of the interior, Ottawa, for construction of the following roads: Banff-Windermere and the Edith Cavell highways, to J. A. Stephen, 249 Argyle Ave., Ottawa; Castle-Laggan highway to G. R. Long, 51 Sparks St., Ottawa; Mount Revelstoke highway to McPherson & Beam, Regina, Sask. J. B. Harkin, commissioner, Dominion Parks branch, Department of the Interior, Ottawa, Ont.

Portage la Prairie, Man.—Contract has been awarded by the municipal council for construction of reinforced concrete culverts to La Cour & Schioler, 858 McDermot Ave., Winnipeg. D. McCowan, secretary-treasurer.

Quebec, Que.—Of the sixty bridges under construction in the province of Quebec, fifteen are in the district of Quebec, the biggest of which being erected, is the Metabetchouan, 600 ft. long and 100 ft. clear of the river. Ivan Vallee, chief engineer, department of public works, Quebec.

Regina, Sask.—Contracts have been awarded by the department of highways, Regina, for construction as follows: Concrete bridge over Wascana Creek, south-east of Regina, E-9-17-19, west of 2nd meridian, to E. J. St. Onge, Maple Creek, Sask. Concrete abutments over Dog Hide Creek near Tisdale, 1-45-15, west of 2nd meridian, to the Parsons Building Co., Regina. Concrete abutments over Swan River, N.E. ¼-22-34,30, west of 1st meridian, to the Parsons Building Co., Regina. H. S. Carpenter, deputy minister.

Riverside, Man.—Tenders will be received by J. H. Putman, secretary-treasurer, up till noon, on Saturday, September 13th, 1919, for the construction of a 16-ft. span girder bridge on the N. of N.E. ¼-20-5-17. Plans and specifications may be secured from the office of the highway commissioner, Winnipeg.

Sarnia, Ont.—Hon. F. G. Macdiarmid, Ontario minister of public works, has communicated with the local Chamber of Commerce to the effect that the government has under consideration the extension of the provincial highway system in western Ontario. The communication refers to the highway which would connect London and Sarnia, and states that probably a survey of the route will be undertaken shortly.

Scarboro Tp., Ont.—Tenders will be received by W. D. Annis, township clerk, up to noon, Tuesday, September 2nd, 1919, for grading and gravelling Courcelette Road, from Kingston Road to Windsor Ave., and Lakeside Ave., from Kingston Road south. Plans and specifications may be seen at the office of the engineers, James, Loudon & Hertzberg, Ltd., 36 Toronto St., Toronto.

St. Jacobs, Ont.—Construction has commenced on the new 16-ft. concrete, provincial county road north of St. Jacobs. Length of road to be built, three miles. Contractor, Lichty Bros., Wellesley.

Toronto, Ont.—At a meeting of the city council, the following by-laws were passed: extension of Duplex Ave. and opening of Cleveland St., $119,211.73; asphalt pavement on Danforth Ave., widening Kingston Rd. from Balsam to Silver Birch Ave., widening Morton Rd., construction of sewer on Queen St. from Pape to Leslie, $84,559; completion of Strachan Ave. bridge, $16,000, and Cherry St. bridge, $100,000. R. C. Harris, commissioner of works.

Vancouver, B.C.—Tenders will be received by Wm. McQueen, city clerk, up to 2 p.m., Tuesday, September 2nd, 1919, for the construction of a protection pier and fender, at Granville Street bridge. Plans and specifications may be obtained at the city engineer's office, city hall.

Welland, Ont.—City council passed a by-law providing for the construction of a cement sidewalk on the west side Crowland Ave. City Engineer, Charles L. Coulson.

York Township, Ont.—Contracts have been awarded by the county commissioners for construction of the following concrete structures: Abutment for Baldwin bridge to R. H. H. Blackwell, Aurora, Ont., $2,290. Ramsden bridge to W. H. Sheridan, Toronto, Ont., $1,512. Frank Barber, engineer, 40 Toronto St., Toronto.

WATER, SEWAGE AND REFUSE

Brantford, Ont.—The city council has decided to enlarge the pumping station at the waterworks plant. Two new engines and two pumps are being installed at present.

Chatham, Ont.—The engineers are considering a proposition to pump water to Chatham from the Snye. This source of supply will probably be incorporated in the official report.

Edmonton, Alta.—The department of public works, Ottawa, is considering an alternative route for the sewer outlet of the city, to remove same from its present position close to the penitentiary grounds. Commissioner Ormsby.

Edmonton, Alta.—Construction of the clear water basin has commenced. Estimated cost, $30,000. A. W. Haddow, city engineer.

Edmonton, Alta.—Tenders will soon be called for construction of a sewer for the Swift packing plant. Estimated cost, $45,000. A. W. Haddow, city engineer.

Halifax, N.S.—In a report presented to the city board of health, Dr. K. G. Mahabir recommended that the city abandon Chain Lake as a source of supply; purchase certain properties on the water-sheds and draw water from Long Lake and Spruce Hill Lake; extend the existing intakes, which are in the "dead" ends of the lakes into deeper water near the centre.

Hespeler, Ont.—Tenders will be received until 5 p.m., August 30th, by the town council for laying approximately 5,448 lin. ft. of water mains. Town clerk, M. E. Jardine. Engineer, Herbert Johnston, 130 Lancaster St. E., Kitchener, Ont.

London, Ont.—Contract has been awarded by the London township council, for construction of Ox Bow drain, to W. P. Godson & Co., 30 Leopold St., Toronto. Contract price, $10,146.95. Rejected tenders, E. P. Murray, Stratford, $13,300, Peter Winter, Parkhill, $19,500. Mary Grant, clerk.

Moncton, N.B.—The city engineer's department will construct sewer along Victoria Ave., Wesley to Pearl St. J. Edington, city engineer.

Moncton, N.B.—Contract has been awarded by the city council for construction of sewers on Henry and Cornell St., to Lewis Stephens & Co., St. John, N.B. Contract price, $12,786.25.

Parry Sound, Ont.—Contract has been awarded by the town council for construction of a 6-in. water main on Armstrong Ave., to R. Kenny.

Quebec, Que.—Plans and estimates are being prepared by the department of works for construction of sewers in St. Roch's, St. Sauveur and St. Malo on the south side, and along the Limoilou on the north side of the St. Charles River. W. D. Baillairge, city engineer.

Sandwich, Ont.—Town council has awarded contracts for sewers as follows: Randolph and Rankin Ave., to Merlo, Merlo and Ray, $7,000; Felix Ave., to Pettypiece, Ltd., $4,000; Matchet Rd., and Manchester Ave., to West & Sheehan, $15,000.

Sarnia, Ont.—Tenders will be received until 10 a.m., September 1st, by the Sarnia Cemetery Co., for construction of water works system of piping in Lake View Cemetery. M. A. Sanders, secretary, 215½ Front St. N., Sarnia.

Toronto, Ont.—At a recent meeting of the city council, the following by-laws were passed: for relief sewers, $394,000; for extending and improving waterworks, $386,000. R. C. Harris, commissioner of works.

Welland, Ont.—City council passed a by-law for the construction of a sewer on River Road. City engineer, Charles L. Coulson.

Welland, Ont.—A report on the construction of a sewer in the north ward to Parkway Heights was submitted to the city council by City Engineer Coulson. The total cost of the proposed sewer is $39,369. Consideration of the report was laid over until next meeting.

Winnipeg, Man.—The following tenders were received by the department of public works, Winnipeg, for excavating 300,000 cu. yds. material in drainage district No. 2; high tender, Lunt Engineering Co., Winnipeg, 26c. per cu. yd.; low tender, Carter, Halls & Aldinger, Winnipeg, 22.5c. per cu. yd. Estimated cost of work, $81,000. G. A. Grierson, minister.

Woodstock, Ont.—Plans will soon be completed for the treatment and disposal of sewerage for the south side intercepting sewer scheme. By-law to be submitted to the ratepayers, calls for an expenditure of $110,000. City engineer Ure.

York Tp., Ont.—Tenders will be received by the township engineer, Frank Barber, 40 Jarvis St., Toronto, up to 12 o'clock noon, Saturday, September 6th, 1919, for the construc-

No Damage at these Curves!

Entrance to Queen Victoria Park, Niagara Falls, Ont. Roadway surface treated in June 1918 with "Tarvia-B."

When swift and heavy automobiles sweep around the bend of an ordinary macadam road the tires slip sidewise—not enough to skid, to be sure, but enough to rub and rasp the brittle macadam until the stones loosen and the surface ravels.

No road is better than its curves.

The curves are always the first spots in a road that need repair.

With plain macadam construction the curves are a *constant source of trouble and expense.*

Not so with Tarvia-macadam: Note the excellent condition of the curves in the Tarvia roads pictured here.

Curves have no terrors for Tarvia, because when it is used as a binder it forms a tough matrix for the crushed stone. Not only has Tarvia greater bonding power than natural binder, but it has the further element of *plasticity*, so that it yields instead of crumbling.

Tarvia solves motor-traffic problems.

The use of Tarvia reenforces the road-surface and makes it strong enough to resist motor-driven traffic, which to-day is the biggest problem of the roadmaker.

Likewise with the erosion problem: Water on steep grades washes out plain macadam but does not harm the Tarvia-macadam because it is absolutely waterproof.

And remember, Tarvia roads are also *frost-proof, mudless, and dustless,* and cost less than any other type of good-road construction.

Illustrated booklet describing the various Tarvia treatments free on request.

The Barrett Company LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER
ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

Summit Crescent, West Crescent Height, Westmount, a suburb of Montreal. Treated with Tarvia.

Special Service Department

This company has a corps of trained engineers and chemists who have given years of study to modern road problems. The advice of these men may be had for the asking by any one interested. If you will write to the nearest office regarding road problems and conditions in your vicinity, the matter will have prompt attention.

Main Driveway, Queen Victoria Park, Niagara Falls, Ont., north of the Administration Building.

tion of a 6-inch cast-iron water main in Morningside Ave., Lavinia Ave., Ostend and Runnymede Rd., s., 2,784 ft. Plans and specifications may be obtained at the office of the engineer.

York Tp., Ont.—Tenders will be received by the township council for construction of 6-in. cast-iron water mains on Amherst Ave., Jesmond Ave., Ashbury Ave., Roach Ave., Humewood Ave., about 5,214 ft.; Craydon Ave., Ray Ave., Rutherford Ave., Victoria Blvd., Eglinton Ave., Brownhill Ave., Barr Ave., Elora Ave., about 5,066 ft.; Cliff St., Bushey Ave., Jasper Ave., Langden Ave., Orla Ave., Chryessa Ave., Gray Ave., Outlook Ave., Humber Crest Blvd., about 6,139 ft.; Lauder Ave., about 3,200 ft.; Mitchell Ave., about 1,136 ft.; Northland Ave., Lapp St., Spears St., McCormack St., about 3,803 ft.; Northcliffe Blvd. North, Lavinia Ave., Runnymede Rd., Ostend Ave., about 3,043 ft. Engineer, Frank Barber, 40 Jarvis St.

LIGHT, HEAT AND POWER

Kitchener, Ont.—Tenders, addressed to B. G. Michel, city engineer, will be received until noon, Thursday, September 11th, 1919, for the supply and erection of a motor and centrifugal pump, together with appurtenances. Drawings and specifications may be seen at the office of the city engineer.

Moncton, N.B.—Council authorized the city engineer to ascertain cost of erection and installation of an electric light plant at the pumping station for the use of the city, and supply of lights used in the streets and city buildings. J Edington, city engineer.

Nokomis, Sask.—Tenders will be received until 6 p.m., August 30th, by the town council for installation of an electric lighting system. W. A. Armour, secretary-treasurer.

Pickering, Ont.—The Hydro-Electric Power Commission is willing to electrify the old Toronto and Eastern Ry through Pickering, Oshawa and Bowmanville, provided town of Pickering passes by-law guaranteeing bonds to finance the undertaking. Sir Adam Beck, chairman.

RAILWAYS

Brantford, Ont.—City engineer is preparing plans and specifications for double-track approaches to the St. Paul's Ave. subway. Tenders will soon be called. T. H. Jones, city engineer.

Calgary, Alta.—The C.N. Ry. is double-tracking the Drumheller line, constructing concrete bridges, new yards and tunnels. Estimated expenditure for 1919, $1,000,000. A. E. Warren, general manager, western lines.

Kitchener, Ont.—The Grand River Ry. will construct a switch line into the Ames, Holden Tire Co. property along Charles St., as soon as the council grants permission.

Kitchener, Ont.—The board of trade of Kitchener and Wellesley township will request the Grand River Railway to extend their line through Kitchener to Linwood.

Port Arthur, Ont.—An offer has been received by the city council from the Ontario Hydro-Electric Power Commission to take over and operate the street railways of Port Arthur and Fort William. Sir Adam Beck, chairman.

Prince Rupert, B.C.—The C.N. Ry. contemplate large extensions and improvements, new freight sheds, extended yards, new depot, extensions to roundhouse, etc. J. S. Woodward, secretary, board of trade. B. T. Chappell, general superintendent, C.N. Ry.

Toronto, Ont.—The Ontario Railway Board is requesting the Toronto Street Ry. to state when it will construct the Pape Ave. car line. Vice-Chairman Ingram.

Toronto, Ont.—The ratepayers of Ward No. 7 are requesting the city council to extend the civic car lines through the Runnymede-Annette district, taking precedent over extension along Bloor St. through the Runnymede-Jane district.

FACTORIES AND LARGE BUILDINGS

Brockville, Ont.—A smelter may be built here by the Consolidated Iron and Steel Corporation, Ltd., 20 King St. East, Toronto, recently incorporated with a capital of $8,000,000, and backed by Toronto and Detroit interests.

Calgary, Alta.—Permits issued by the city of Calgary for July, 1919, $280,000; July, 1918, $45,000.

Calgary, Alta.—At a meeting, called by the board of trade, the citizens present decided to raise $300,000 to erect a veterans' clubhouse. P. L. Naismith, chairman.

Calgary, Alta.—Contract has been awarded for general work in the construction of additions to the Western Canada College, to Bennett and White Construction Co. Plumbing and heating, J. B. Rogers. Architect, Charles Hay.

Calgary, Alta.—Plans are being prepared by C. W. Fairn, superintendent of buildings, department of education, for a new high school, which will probably be erected on the north hill property, corner of First St. West and Ninth Ave. Estimated cost, $350,000.

Dundas, Ont.—Board of works decided to erect a new steel bridge on Head St. Town clerk, J. J. Fry.

Fort William, Ont.—The site of the Black elevator, recently destroyed by fire, has been purchased with the intention of constructing immediately a large modern elevator. G. R. Duncan.

Galt, Ont.—It is proposed to construct a residence for the Young Women's Christian Association. Estimated cost, $50,000.

Guelph, Ont.—The chamber of commerce contemplates construction of a large covered skating rink. Estimated cost of building, $40,000.

Hamilton, Ont.—Tenders, addressed to Charles G. Booker, mayor, chairman of the board of control, will be received by S. H. Kent, city clerk, up to 10 o'clock a.m. on Tuesday, September 2nd, for the erection of one steel shelter on the Central Market grounds, according to plans and specifications to be seen at the office of Laurence Munro, architect, 36 Main St. East, or at the office of the city engineer, city hall.

Headingly, Man.—The board of the Phœnix school district has decided to erect an addition to school.

Ingersoll, Ont.—By-law will be prepared to provide $120,000 for the erection of a sixteen-roomed Central school.

Islington, Ont.—The Etobicoke township council has granted permission to the Ontario Hydro-Electric Power Commission to construct a new pumping station on College St., at Mimico Creek.

Kitchener, Ont.—The F. W. D. Auto Co. will commence construction of their new factory immediately.

Kitchener, Ont.—The G.W.V.A. of Waterloo and Kingston propose to reorganize the 108th regiment, provided the government will construct and equip a suitable armory. Lieut.-Col. W. M. O. Lochead.

London, Ont.—Permits issued by the city architect show the following construction: Theatre on Dundas St., for J. and J. J. Allen, $100,000, contractor, N. McLeod, Toronto; brick warehouse $25,000, office $15,000, stable $10,000, for the Canadian Oil Co., contractor, R. G. Wilson and Son.

Niagara Falls, Ont.—By-law was passed by council for construction of a technical school as an adjunct of the collegiate institute. Estimated cost, $100,000.

Oshawa, Ont.—Tenders will be received until noon, September 3rd, by the board of education for construction of a four-room addition to Mary St. School. S. B. Coon & Sons, architects, Excelsior Building, Toronto. P. H. Punshon, secretary, Oshawa.

Ottawa, Ont.—The board of the collegiate institute have decided to construct a new building on Percy, Chrysler, First and Carling Ave. Estimated cost, $150,000.

STEEL BARS
FOR CONCRETE REINFORCEMENT
ROUNDS, SQUARES, TWISTED SQUARES,
FLATS, ANGLES.

Preston, Ont.—Contract has been awarded by Otto Homuth, for construction of a new factory to Norman Hipel, Preston.

Regina, Sask.—The Goodyear Tire and Rubber Co. has announced its intention of building a $75,000 block here at once to serve as western headquarters.

Regina, Sask.—Tenders will soon be called for construction of a combined office, warehouse and storage building on Sixth Ave. and Osler St., for Maclean Grocery Co. and Lloyd Fruit Co. Architect, R. J. Bunyard, Moose Jaw.

Regina, Sask.—Tenders will soon be called for construction of a fireproof building, to be equipped with new, modern machinery, to be used as a bakery. Time of completion, December 1st. Estimated cost, $80,000. G. Gillam, president, Manitoba and Western Ontario Bakers' Association.

Salt Springs, N.S.—Tenders will be received by the C.N. Ry. until 12 o'clock, noon, August 30th, for construction of a frame station building and platforms. Plans, etc., offices of chief engineer, Moncton, N.B., resident engineer, Truro, N.S., C.N. Ry. agent, Amherst, N.S. F. F. Brady, general manager, eastern lines.

Sandwich, Ont.—Contracts have been awarded by the school board for construction of a four-roomed school on Wyandotte St., to Wells and Grey. Contract price, $61,000. Plumbing and heating to Windsor Hardware Co. Contract price, $14,000.

Selkirk, Man.—Bulk and separate tenders will be received by E. D. Tuttle, architect, McArthur building, Winnipeg, up to 4 p.m., Wednesday, September 3rd, 1919, for the erection of a Collegiate building for the Selkirk S.D. Blue prints and specifications may be obtained from Mr. Comber, Selkirk, or from the architect.

St. Thomas, Ont.—The F. J. Harding Co. contemplates additions to their factory.

Toronto, Ont.—A new Strand theatre will be erected on the present site, Yonge St., to seat 3,600. Estimated cost, $400,000. Architect, T. Lamb, New York.

Toronto, Ont.—Tenders will be received by the board of control until noon, September 2nd, for public lavatories at Centre Island. T. L. Church, chairman.

Toronto, Ont.—The board of control has instructed the city architect to prepare plans, specifications and estimates of the new stadium to be erected in Rosedale.

Toronto, Ont.—Plans have been completed for an extension to the Western hospital. Estimated cost, $500,000.

Toronto, Ont.—The Imperial Bank of Canada has purchased the north-west corner of King and Yonge Sts. and will erect a new modern building.

Toronto, Ont.—Tenders will be received by the University of Toronto for construction of a building for the Anatomy department. Architects, Darling & Pearson, 2 Leader Lane, Toronto.

Toronto, Ont.—Tenders will be received by the department of education, 155 College St., until 4 p.m., September 10th, for all trades for enlargement of Bedford Park School, Ranleigh Ave. W. C. Wilkinson, secretary-treasurer.

Vancouver, B.C.—A group of local business men, headed by Gordon Jonah, of the Jonah-Piat Co., have formed a company and will erect a woolen mill.

Vancouver, B.C.—T. H. Laslett will construct a new brick factory at 721 Seymour St. Estimated cost, $10,000.

Vancouver, B.C.—The Union Bank has received permit to construct a modern bank building. Estimated cost, $300,000.

Vanderhoof, B.C.—No contract was awarded for construction of Vanderhoof school, for which tenders were called for August 8th. A. E. Foreman, engineer, department of public works, Victoria, B.C.

Whitby, Ont.—The board of Education has decided to proceed with the preparation of plans for the re-building of the Dundas St. School at a cost of about $10,000, and the erection of a new six-room school in the West Ward at an approximate cost of $40,000. Secretary, Dr. C. F. McGillivray.

Willowdale, Ont.—Tenders will be received up to noon, September 10th, 1919, for alterations to York Cottage, Willowdale (North Yonge St.). Plans and specifications may be seen at the office of the architects, James, Loudon & Hertzberg, Ltd., 36 Toronto St., Toronto.

Winnipeg, Man.—A large sheet-iron cattle shed will be constructed by the Public Market Co. at the stockyards. Estimated cost, $40,000.

Winnipeg, Man.—Contract has been awarded by the Marshall Wells Hardware Co., for erection of a warehouse on Rue Des Meurons, St. Boniface, to Carter, Halls & Aldinger. Contract price, $70,000.

Winnipeg, Man.—The Greater Winnipeg Water District Ry. is preparing plans for offices, waiting rooms and a roundhouse. Construction will probably commence before winter.

MISCELLANEOUS

Brockville, Ont.—The Consolidated Iron and Steel Corporation, Ltd., contemplates erection of a pig-iron smelter. Office, 20 King St. E., Toronto.

Cobourg, Ont.—Town council has decided to purchase a motor fire truck equipped with chemical tanks. D. Denton, mayor.

Depot Harbor, Ont.—Tenders will be received until 12 o'clock noon, September 12th, by the department of public works, Ottawa, for renewal of wharf. Plans, etc., at offices of district engineers at Midland, Ont.; Equity building, Toronto, Ont., and post-office at Depot Harbor. R. C. Desrochers, secretary.

Eburne, B.C.—Contract has been awarded by the department of public works, Ottawa, for dredging the north arm of the Fraser River, near Eburne, B.C., to Pacific Dredging Co. Approximate excavation, 950,000 cu. yds. Contract price, 15 cents per cu. yd. R. C. Desrochers, secretary.

Hamilton, Ont.—The works department are preparing plans and estimates for a new concrete coal dock to replace the present wooden structure at West Hamilton. E. R. Grey, city engineer.

Kitchener, Ont.—The city council has passed a motion that equipment for road construction be purchased. Alderman Asmussen.

Lethbridge, Alta.—The ratepayers will vote upon a by-law on September 2nd, providing $35,000 for purchase and installation of water meters.

Ottawa, Ont.—Tenders will be received by John A. Pearson, architect, Centre Block, Parliament Hill, Ottawa, until noon, September 6th, 1919, for the office furniture required for the Parliament Building. Plans, specifications and any other information required may be obtained at the architect's office.

Pandora, Alta.—The Central Alberta Irrigation Association has been formed to bring under irrigation all that section of country lying north of the Red Deer River, from which water can be secured by tapping the Saskatchewan River, using Buffalo Lake as an immense reservoir. Approximate acreage, 2,000,000. President of association, W. Winning, Winnipeg, Man.

Prince Albert, Sask.—P. Burns Co., Ltd., has commenced work on excavations, shipping dock, new transfer spurs and enlargement of the yards. John Burns, general manager, Calgary, Alta.

Purple Springs, Alta.—An irrigation system is contemplated for the surrounding district. Area to be watered, 78,000 acres. J. J. McLellan, Purple Springs, Alta.

Quebec, Que.—The battlefields commission will urge the government to complete the battlefields park scheme, by ac-

quiring all the ground between the citadel and the existing park lands, in addition to the property lying to the west. Estimated additional cost, $500.000.

Sydney, C.B.—The Dominion Iron and Steel Co. have closed down their plant and have placed every available man on the construction of the new plate rolling mill.

Toronto, Ont.—At a recent meeting of the city council the following by-laws were passed: For purchase of additional parks and playgrounds, $150,000; for harbor improvements, $496,000; for purchase of cars for civic car line, $200,000. R. C. Harris, commissioner of works.

Toronto, Ont.—It is said that the Toronto Street Ry. are constructing a number of new palace cars, and that they will be placed in service before winter.

Toronto, Ont.—One mile of cribwork for the new harbor front has been completed and the concrete caps will soon be placed in position. Estimated expenditure, $900,000.

Toronto, Ont.—Tenders will be received until 12 o'clock noon, September 2nd, by the board of control, city hall, for supply and delivery of electric motors. T. L. Church, chairman.

Toronto, Ont.—The board of control contemplates providing for a system of motor buses. Estimated cost, $250,000. T. L. Church, mayor.

Toronto, Ont.—The city council has requested an additional report relative to the safety of the Royal Gorge at Exhibition Park, the Cascades and Scenic Ry. at Scarboro Beach and the Old Mill at the Island.

Toronto, Ont.—The city council may appoint a committee of three to prepare to take charge of the Toronto Ry. at the expiration of its franchise in 1921; to study conditions relative to extensions, type of cars, etc. R. Cameron, controller.

Vancouver, B.C.—C. C. Ballantyne, minister of marine, Ottawa, will decide location in Vancouver harbor for the six new deep water wharves. Estimated cost, $5,000,000.

Vancouver, B.C.—The city council has decided to purchase three two-ton trucks, $12,090; one one-and-a-half-ton truck, $3,060; and one one-ton truck, $2,595, for use of city scavenging department.

Waterloo, Ont.—Contract for steelwork for factory for the F. W. D. Auto Co. has been awarded to the Dominion Bridge Co., Toronto.

Waterloo, Ont.—The board of park management will erect a greenhouse, 15 ft. 6 in. by 58 ft. 4 in. Architect, Lord and Burnham, Toronto.

Winnipeg, Man.—Contract has been awarded by the Greater Winnipeg Water District Ry. for construction of gravel bins, to Carter, Halls & Aldinger. Contract price, $40,000.

Winnipeg, Man.—The committee on fire, water, light and power have decided not to award contracts for permanent repairs to roof of six-million gallon reservoir at McPhillips pumping station. Temporary repairs will be made by the city engineer's department, cost $300. W. P. Brereton, city engineer.

Tenders Called For

TENDERS FOR PUMP AND MOTOR

Sealed tenders, addressed to the undersigned, will be received until noon, Thursday, September 11th, 1919, for the supply and erection of a motor and centrifugal pump, together with appurtenances.

Drawings and specifications may be seen at the office of the City Engineer, Kitchener, Ont.

B. G. MICHEL, C.E.,
City Engineer. 333

TENDERS FOR GRADING

Tenders will be received by the Clerk of the Township of Scarboro up to noon, Tuesday, September 2nd, 1919, for grading and gravelling—

(a) Courcelette Road from Kingston Road to Windsor Avenue.
(b) Lakeside Avenue from Kingston Road south.

Plans and specifications may be seen at the office of the engineers, James, Loudon & Hertzberg, Limited, 36 Toronto Street, Toronto.

J. G. CORNELL, Reeve. W. D. ANNIS, Clerk. 336

TENDERS FOR ALTERATIONS TO BUILDING

FOR YORK COUNTY CHILDREN'S AID SOCIETY

Tenders will be received up to noon, September 10th, 1919, for alterations to York Cottage, Willowdale (North Yonge Street).

Tenders must be marked, sealed and addressed to Mr. R. P. Coulson, 57 Adelaide St. East.

Plans and specifications may be seen at the office of the architects, James, Loudon & Hertzberg, Limited, 36 Toronto Street, Toronto.

HON. G. S. HENDRIE, President. W. D. ANNIS, Secretary. 334

PARLIAMENT BUILDING, OTTAWA

TENDERS WANTED FOR OFFICE FURNITURE

Sealed tenders will be received by the undersigned, until noon, September 6th, 1919, for the "Office Furniture," required for the above building.

All tenders to be based on the manufacture, supply and delivery at the building of the "Office Furniture," as shown and described by the plans and specifications.

The work of this contract shall be proceeded with immediately upon the signing of the same, and continued as may be directed and in such a manner as to ensure completion of the whole work by December 20th, 1919.

Plans, specifications, and any other information required can be obtained at the Architect's Office, Centre Block, Parliament Hill, Ottawa.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Minister of Public Works, for a sum not less than five per cent. (5%) of the amount of the tender, which will be forfeited if the parties tendering decline to enter into a contract when called upon to do so. If the tender is not accepted, the cheque will be returned. If the tender is accepted, an additional cheque for a sum equivalent to five per cent. (5%) of the tender must be deposited before the contract is signed. The total security will be forfeited if the contractor fails to complete the work contracted for.

Payment for material delivered and accepted, will be made monthly.

The lowest or any tender not necessarily accepted.

Envelopes containing tenders to be marked: "Tender for Office Furniture," and addressed to the undersigned.

JOHN A. PEARSON, Architect,
J. O. MARCHAND, Associate.

A Weekly Paper for Civil Engineers and Contractors

Pressure Rise Caused by Gradual Gate Closure

Application of Professor Joukovsky's Theory of Maximum Water-Hammer—Solution of Problem by Arithmetic Integration—Derivation of Formulas—Paper Presented to the American Society of Civil Engineers

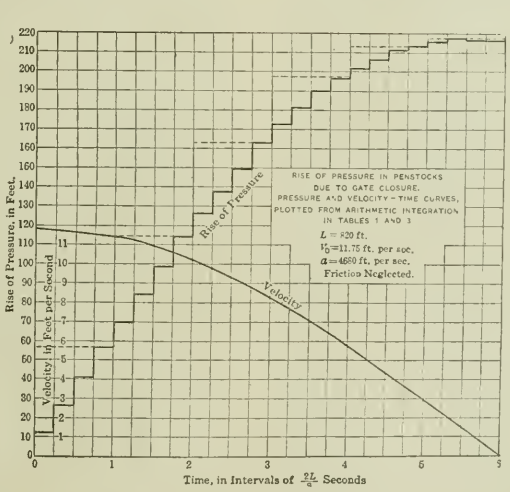
By NORMAN R. GIBSON

Hydraulic Engineer, Hydraulic Power Co., Niagara Falls

THE purpose of this paper is to show how the excess pressure in penstocks caused by the gradual closing of turbine gates may be determined from Professor Joukovsky's theory of water-hammer. It will be assumed that the theory of pressure waves, their amplitudes, and speeds of propagation, as formulated by him and proved by his experiments, may be accepted as correct.

At the risk of wearying the reader who is familiar with Joukovskys' work, it is necessary, in connection with what is to follow, to summarize as briefly as possible the principles demonstrated a number of years ago by the distinguished Russian. For a partial translation of his work, the reader is referred to Miss O. Simin's paper entitled "Water Hammer," in the Proceedings of the American Water Works Association, 1904, page 341, which should be examined carefully by every student of this subject.

Joukovsky's experiments, made in 1908 at Moscow, were confined to the instantaneous stopping of the flow of water in long pipes. By his experiments he was able to prove the soundness of his analytical determination of the maximum rise of pressure that would occur when the flow of water in a pipe was suddenly arrested. The casual thinker at first would imagine that—as force is equal to the product of mass by acceleration—an infinite pressure would be produced in a pipe if the water flowing in it were stopped instantaneously. On second thought, he would realize that neither the water column nor the walls of the pipe are rigid, and therefore the pressure caused by the shock of stopping the flow suddenly is relieved by the slight compression of the water and the expansion of the walls of the pipe. It was the effect of these two factors that was determined by Professor Joukovsky. He showed that the shock pressure is transmitted along the column of water in the pipe in waves similar to sound waves; and that the shock pressure is proportional to the destroyed velocity of flow and to the speed of propagation of the pressure waves. This speed depends on the compressibility of water, on the elasticity of the materials of the pipe, and on the ratio of thickness of the walls of the pipe to its diameter. In other words, if the speed of the pressure wave is known, the maximum pressure produced (called water-hammer) by instantaneously stopping water flowing in a pipe at any velocity may be calculated.



RISE OF PRESSURE IN PENSTOCKS DUE TO GATE CLOSURE.

FIG. 1—PRESSURE AND VELOCITY-TIME CURVES PLOTTED FROM TABLES 1 AND 3

Joukovsky's formula for water-hammer is:—

$$h = aV/g \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

where h = excess pressure, in feet;
V = velocity of flow in the pipe, in feet per second;
g = gravitational unit, in feet per second per second;
and a = velocity of the pressure wave, in feet per second, which is determined by the formula:—

$$a = 12 \div [(W/g)(1/k + d/Ec)]^{\frac{1}{2}} \quad \ldots\ldots\ldots\ldots (2)$$

where W = weight of a cubic foot of water, in pounds;
k = voluminal modulus of water, in pounds per square inch;
d = diameter of pipe, in inches;
c = thickness of pipe walls, in inches;
E = modulus of elasticity of material of pipe walls, in pounds per square inch.

Joukovsky showed also that the shock pressure is transmitted along the pipe with constant intensity and "at constant velocity, which seems to be independent of the intensity of the shock."

"The speed of propagation of the pressure wave remains the same, whether the shock is caused by arresting the flow of a column of water moving in a pipe, or by suddenly changing the pressure in the column of water (flowing or standing) in any part and by any other means."

"If the water column continues flowing, such flow exerts no noticeable influence upon the shock pressure. In a pipe from which water is flowing, the pressure wave is reflected from the open end of the pipe, in the same way as from a reservoir with constant pressure."

"The phenomenon of periodical vibration of the shock pressure is completely explained by the reflection of the pressure wave from the ends of the pipe, i.e., from the gate and from the origin [of the pipe]."

(These quotations are from Miss Simin's "Water Hammer.")

Pressure waves, after travelling up the penstock to the

origin or point of relief and back to the gate, are reflected and transmitted again over the same course, as waves of rarefaction or sub-normal pressure. In this manner pressure waves, alternately super-normal and sub-normal, travel up and down the penstock until damped out by friction. During the time taken by the wave to traverse its course from gate to origin the pressure at the gate remains at its full value, either super-normal or sub-normal, as the case may be.

Briefly stated, then, the premises are: that when water flowing in a pipe is suddenly arrested, certain pressure waves, the characteristics of which are known, are produced and

propagated along the pipe at constant speed and constant magnitude, and that the speed and magnitude of these waves may be calculated for any given conditions.

Fundamental Equations

It is the writer's intention to apply herein this theory of pressure waves to the phenomena which occur when the gates of a turbine at the end of a penstock are gradually closed. The damping effect of friction on the pressure waves will be neglected during the time of closure. The variable velocity of the pressure wave due to the difference in density of the water at the top and bottom of the penstock will also be neglected. For the sake of simplicity, it will be assumed that the gate opening is closed uniformly from full open to shut by a governor which moves the gates at uniform velocity from the beginning of its stroke to the end, and that the area of gate opening is directly proportional to the amount of gate movement. It may be stated here, parenthetically, that the resulting formulas may be modified, easily, to suit any method of gate closure, whether the speed of closing and the relation of governor movement to area of gate opening is uniform or variable.

When the gates of a turbine are closed gradually the velocity of the water in the penstock is reduced to zero and the pressure in the penstock rises. It is frequently assumed that the reduction in velocity takes place uniformly, but the rise of pressure, which commences immediately after the gates begin to move, increases the velocity of discharge through the gate opening, and, during the early part of the gate movement, tends to diminish the rate at which the flow of the water is retarded. This variable rate of retardation, during the time the gates are being closed, has an important bearing on the resulting rise of pressure, and it is necessary to take it into consideration by determining the relation between the velocity of flow and the pressure in the penstock. This relation may be expressed by the equation:—

$$V_o = B_o(H_o)^{\frac{1}{2}} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (3)$$

where V_o = initial velocity, in feet per second, of the water in the penstock before shut down;

H_o = normal net head, in feet;

and B_o = a number representing the gate opening. The value of B_o is best determined from the known value of V_o and H_o, but, in fact, B_o is the ratio of the area of the penstock multiplied by $(2g)^{\frac{1}{2}}$ times the coefficient of discharge of the gate opening.

At any time during the closing of the gates the relation between V, B, and H would be expressed by the general formula, $V = B(H)^{\frac{1}{2}}$. If the gates are closed in the time, T, and t is the time from the beginning of the stroke to any time before the end of the stroke, the value of B_t (that is, B at the end of the time, t) for uniform closing, would be $(1-t/T)B_o$. During the time, t, the pressure in the penstock has risen an amount, h_t, so that the net head, H_t (that is, H at the end of the time, t) would be equal to H_o+h_t. There-

* Non-uniform gate motion.

fore, the expression for the value of V_t (that is V at the end of the time, t) is:

$$V_t = (1-t/T)B_o(H_o+h_t)^{\frac{1}{2}} \quad \ldots\ldots\ldots\ldots\ldots\ldots (4)$$

Calculation by Arithmetic Integration

Before proceeding with the analytical determination of h_t, it will perhaps make the work clearer to show first, by a numerical example, how h_t may be obtained by the trial-and-error method of arithmetic integration. Assume that the gate, instead of being moved in a continuous uniform manner, is closed by a series of small instantaneous move-

ments with a slight pause between each movement. Each little movement of the gate would destroy instantaneously a small part, ΔV, of the velocity, V_o, and, since this part of the velocity is destroyed instantaneously, the rise of pressure, according to Joukovsky, would be $h = a\Delta V/g$. When the first instantaneous movement has taken place, let a pause of time, t, elapse before the next movement. Then $\Delta V = V_o - V_t$, and $h_t = a(V_o - V_t)/g$.

By these equations and Equation (4) a numerical example may now be solved, and at the same time there will be explained other interesting phenomena caused by the closing of the gates and the pressure waves produced thereby. The analytical work may then be more readily understood.

Let $L = 820$ ft.;
$V_o = 11.75$ ft. per sec.;
$H_o = 165$ ft.;
$T = 2.1$ sec. (For convenience, T has been chosen an even multiple of $2L/a$).
$a = 4{,}680$ ft. per sec. (This value of a is chosen simply because this example was worked out by the writer for a pipe in a tunnel and concreted in. The expansion of the pipe walls, therefore, was neglected. For any condition, a may be obtained by Equation (2).

Since $V_o = B_o(H_o)^{.5}$, then $B_o = 0.91476$.

Assume that the gates are closed in 24 successive instantaneous movements. The time elapsing between each movement would then be 0.0875 sec. After the first of these movements had taken place the gates would have been closed one-twenty-fourth of their opening, and the number representing the gate opening would have been reduced by one-twenty-fourth of its value, that is, $0.91476/24 = 0.038115$. At each of the successive movements the value of B is reduced by the same amount, as the gate motion is assumed to be uniform. It will be necessary, however, to use more than the first three significant figures, and the work may be done on the slide-rule. In this example the recovery of the friction head in the penstock will be neglected.

From the foregoing may now be written the first three columns of Table 1, and the first line of Columns 4 and 5. The table may then be completed as follows: Assume a trial reduction in velocity, caused by the initial instantaneous movement of the gate, and set the figure down in Column 5 under the value of V_o and subtract it from V_o, placing the difference immediately underneath. This trial figure is ΔV, and is assumed to be destroyed instantaneously by the first movement of the gate. A pressure wave, Δh, of magnitude, $a\Delta v/g = 4{,}680(\Delta V)\ 32.2 = 145\Delta V$, is therefore started up the pipe. The product of 145 ΔV is set down in Column 6 opposite ΔV. In Column 7 is recorded the algebraic sum of the value of Δh. Having obtained the figure in Column 7, it is added to the net head, $H_o = 165$, and the sum is set down in the next line lower in Column 4. The result must now be checked, to see that $B(H)^{.5} = V$, where B is 0.8766 and H and V have the values recorded in their respective columns opposite B. If the relation is not satisfied, a new trial value of ΔV must be chosen, and the operations repeated until a check is obtained. After trial, the initial value of ΔV was found to be 0.085. Proceeding in this way, the rise of pressure at the end of 0.35 sec. is found to be 56.80 ft. This rise has taken place in four successive jumps.

At this point it becomes necessary to trace the course of the pressure wave started up the penstock by the initial movement of the gate. This wave has a velocity of 4,680 ft. per sec., and travels at that rate toward the forebay or origin of the penstock; after arriving at the origin it is reflected and returns to the gate at the same velocity. The distance from gate to forebay and return is 1,640 ft., so that the pressure wave takes 0.35 sec. to cover this distance. On its arrival at the gate it is reflected immediately as a wave of sub-normal pressure, and commences its journey again from gate to forebay and back. At the instant the wave becomes sub-normal, however, the gate is given one of its instantaneous closing movements, causing a further reduction in the velocity of the water flowing in the penstock and the consequent rise of pressure incident thereto. Thus, at this instant, two factors have to be taken into consideration: the rise of pressure caused by the fifth little instantaneous movement of the gate and the fall in pressure caused by the change from super-normal to sub-normal of the pressure wave produced by the first or initial movement of the gate which occurred 0.35 sec. before.

By trial-and-error the velocity that has been destroyed by the fifth movement of the gate is found to be 0.258 ft. per sec., and the result is checked as follows. Multiplying 0.258 by 145, the magnitude of the resulting pressure wave is 37.4 ft., and this added to 56.80 would make the total excess pressure existing equal to 94.20 ft., were it not for the fact that the initial wave has returned to the gate and become sub-normal. The amount of the initial wave, as shown by the second line of Table 1, is 12.32, and since it not only falls to

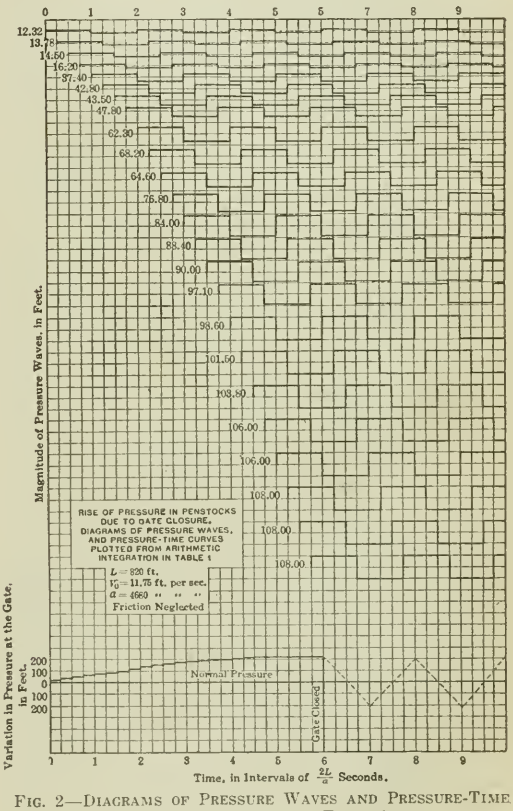

FIG. 2—DIAGRAMS OF PRESSURE WAVES AND PRESSURE-TIME CURVES PLOTTED FROM TABLE 1

zero but passes below zero to a sub-normal pressure of equal amount, making the net excess pressure existing at that instant 69.56 ft. Adding this to the initial net head $H_o = 165$, the value of V is checked as before by the formula, $V = B(H)^{.5}$.

Proceeding then as before, and remembering that the pressure rise caused by the sixth movement of the gate is reduced by the second movement of the gate, and the pressure rise of the seventh movement is reduced by the wave produced by the third movement, and so on, there may be calculated the successive increments of pressure.

For convenience, the time required by the pressure waves to travel from the gate to the origin of the pipe and return to the gate again will be called one interval. The inter-

fering waves referred to in the foregoing paragraph are then always one interval apart.

After the eighth movement of the gate has taken place, it is found that the next excess pressure has reached 114.00 ft. At the instant the ninth movement takes place it must be noted that the pressure wave produced by the first movement of the gate, which has traveled, during the first interval, from the gate to the origin and back as a wave of super-normal pressure, and during the second interval over the same course as a wave of sub-normal pressure, has now returned to the gate and, again becoming super-normal, is again reflected and commences its journey from gate to origin and back. Thus, at the ninth movement of the gate, there must be taken into consideration the pressure wave caused by the instantaneous destruction of the velocity at that instant, the sub-normal wave due to the fifth movement, and the super-normal wave due to the first movement. After adding to the excess pressure existing at the end of the eighth movement, the rise of pressure caused by the ninth movement, there must be subtracted twice the pressure caused by the fifth movement, and there must be added twice the pressure caused by the first movement, or, in other words, there is subtracted twice the difference between the fifth and first waves.

By thus keeping in mind the position of the wave propagated by each movement of the gate, Table 1 may be

TABLE 3—BY ARITHMETIC INTEGRATION
For Data, see Table 1.

(1)	(2)	(3)	(4)	(5)	(6)	(7)
Interval.	Time, T.	Gate, B.	Head, H.	Velocity, V	$145\,\Delta V$, Δh.	$\Sigma\,(\Delta h)$, h_f.

6	2.10	0.0	382.2	0.00		217.2

completed, and the resulting maximum rise of pressure is found to be 217.70 ft.

Fig. 2 is a series of graphical diagrams showing the magnitude of the pressure waves caused by the successive instantaneous movements of the gate. A separate diagram is drawn for each movement, pressure being represented by the ordinates and time by the abscissas. The change from super-normal to sub-normal and *vice versa* is shown at the end of each interval of time. Fig. 1 is the excess pressure-time curve plotted from the figures in Column 7 of Table 1, or, what amounts to the same thing, from the algebraic sum of the pressure waves shown in Fig. 2.

Table 2 shows the method of determining the results when the recovery of friction in the penstock is included, an example being selected where the friction head is an appreciable quantity. The operations are almost identical with those just described, up to Columns 6 and 7. To avoid reference to the foregoing, however, the formation of Table 2 will be described from the beginning. In the first line, opposite $B = 0.4241$, set down Columns 3, 4, and 7, the known values of H_0, V_0, and h_f (friction head). Next, assume a trial reduction in velocity, caused by the initial instantaneous movement of the gate, and set the figures down in Column 4 under the value of V_0, and subtract it from V_0, placing the difference immediately underneath. This trial figure is $\Delta V'$, and is assumed to be destroyed instantaneously by the first movement of the gate. A pressure wave, Δh, of magnitude $= (\Delta V')a/g = (\Delta V')3647/32.2 = 113\Delta V'$, therefore, is started up the pipe. The product of 113 $\Delta V'$ is set down in Column 5 opposite ΔV. In Column 6 is recorded the algebraic sum of the values of Δh. In Column 7 the total friction head, due to the velocity shown in Column 4, is set down, and, in Column 8, the friction head recovered at each operation is shown. For convenience, h_f may be made equal to FV^2, in which F is a coefficient obtained from the known values at the beginning. In the example, $F = 0.3574$. Column 9 shows the sum of the opposite items in Columns 6 and 8. Having obtained the figure in Column 9, it is added to the net head, $H_0 =$ 1,260, and the sum is set down in the next lower line in Column 3. The result must now be checked, to see that $B(H)^{\frac{1}{2}} = V$, where B is now 0.4168, and H and V are the values opposite. If the relation is not satisfied, a new trial value of ΔV must be chosen, and the operations repeated until a check is obtained. After trial, the initial value of $\Delta V'$ was found to be 0.155. The operations for obtaining the figures on the third line are not quite the same as those just described because, after assuming the next trial value of $\Delta V'$, and multiplying it by 113, it must be remembered that the resulting pressure at the gate is reduced by the return of the first wave, which has traveled up to the forebay and back, and now changes to sub-normal and repeats the journey. The time at which the gate is given its second movement has been selected purposely to coincide with the return of the first wave. The item opposite Interval 2, in Column 6, therefore, is the difference between the first two figures in Column 5. The other operations are similar to those already described, and the resulting figures in Columns 3 and 4 are checked similarly with the value of $B = 0.4084$. The succeeding lines are filled in by the same process, always keeping in mind the return of the preceding waves, and whether they change to sub-normal or super-normal. A little study will disclose the fact that the figure in the second line of Column 6 may be obtained by subtracting the figure in the first line of Column 6 from the figure in the second line of Column 5. Similarly, the figure in the third line of Column 6 may be obtained by subtracting the figure in the second line of Column 6 from the figure in the third line of Column 5, and so on.

At this point it is interesting to repeat the trial-and-error work for the foregoing example worked out in Table 1, but using only 6 instantaneous movements of the gate instead of 24. The results are shown in Table 3, and the pressure-time curve in dotted lines in Fig. 1. From these it will be noted that the total rise of pressure is the same as that obtained by the calculations for 24 movements, and, moreover, the resulting pressure at the end of each interval is the same in both cases. Although six movements of the gate, or one movement to each interval of time, are sufficient to determine the pressure rise at the end of each interval, it requires the larger number of movements to obtain intermediate points on the pressure-time curve. If a still greater number of movements is taken, the increments in pressure rise become smaller, and, in the limit, the stepped diagrams similar to Fig. 1 would become a series of smooth curves from the beginning to the end of each interval. The diagram, however, would not necessarily form a smooth curve from the beginning to the end of the closing time, because cusps or changes of curvature at the end of each interval result from the action of the pressure waves in changing at that instant from super-normal to sub-normal or *vice versa*. When the duration of closure is short, the change of curvature in the diagram at the end of each interval is frequently very apparent; but, when the duration of closure is long, the changes of curvature in many cases cannot be detected by the eye. These changes of curvature at the end of the intervals make it difficult to formulate the integration which can so easily be performed by the trial-and-error work already explained.

It is possible, however, to obtain a series of equations, one for each interval of the closing time, that constitute a direct mathematical solution of the problem, without recourse to trial-and-error methods. The foregoing example has been explained in order that the analytical work may be more easily understood, and in order that the method of tracing the course of the pressure waves and keeping track of their periodic changes may be kept clearly in mind. More particularly, it should be borne in mind that though a formula may be written for the pressure rise in the first interval, using only the known quantities existing before the shut-down, the formulas for the pressure rise in any succeeding interval will involve, as one of the known quantities, the value of the pressure rise at the end of the preceding interval. It thus becomes necessary, when calculating the

pressure rise at any time during, or at the end of, the closing of the gate, to obtain first the amount of the pressure rise at the end of each preceding interval. Moreover, if it is desired to determine the pressure rise at any time between the beginning and end of any interval—that is, at any fractional part of an interval—not only is it necessary to determine the pressure rise at the end of each preceding interval, but also the pressure rise at the same fractional part of each preceding interval. This also applies in determining the excess pressure-time curve when the duration of closure is not exactly a whole number of intervals.

NOMENCLATURE

L = length of penstock, in feet;
a = velocity of pressure wave, in feet per second;
g = acceleration due to gravity, in feet per second per second;
$2L/a$ = one interval of time;
T = governor time, in seconds, *i.e.*, total duration of gate closure;
$T_1, T_2, T_3, \ldots T_n$ = Time at the end of the 1st, 2nd, 3rd, ... nth interval;
$t_1, t_2, t_3, \ldots t_n$ = any time during the 1st, 2nd, 3rd, ... nth interval;
n = any number of intervals; the final interval in the time, T, need not be complete;
H_0 = normal net head, in feet;
$h_1, h_2, h_3, \ldots h_n$ = excess pressure above normal, in feet, existing at the end of the 1st, 2nd, 3rd, ... nth interval, *i.e.*, at the times, $T_1, T_2, T_3, \ldots T_n$;
$h_{t_1}, h_{t_2}, h_{t_3}, \ldots h_{t_n}$ = excess pressure above normal, in feet, at any time during the 1st, 2nd, 3rd, ...nth interval, *i.e.*, at the times, $t_1, t_2, t_3, \ldots t_n$;
V_0 = initial velocity, in feet per second, of the water in the penstock before shutdown.
$V_1, V_2, V_3, \ldots V_n$ = velocity, in feet per second, of the water in the penstock at the end of the 1st, 2nd, 3rd, ... nth interval;
$V_{t_1}, V_{t_2}, V_{t_3}, \ldots V_{t_n}$ = velocity, in feet per second, of the water in the penstock at any time, t_1, t_2, t_3, ... t_n, during the 1st, 2nd, 3rd, ... nth interval;
$B_0 = V_0/(H_0)^{1/2}$ = a number representing the gate opening;
$S_{t_1} = (a/g)^2(1-t_1/T)^2B_0^2$
$S_{t_2} = (a/g)^2(1-t_2/T)^2B_0^2$
$S_{t_n} = (a/g)^2(1-t_n/T)^2B_0^2$
$C_{t_1} = (2a/g)(V_0-V_{t_1})$
$C_{t_2} = (2a/g)(V_1-V_{t_2})-C_{t_1}$
$C_{t_n} = (2a/g)(V_{n-1}-V_{t_n})-C_{t_{(n-1)}}$
F = a friction factor such that FV^2 = total loss, in feet of head, for velocity, V
$R_0 = (a/g)V_0$
$R_{t_1} = h_1+(a/g)V_1-C_{t_1}$
$R_{t_2} = h_2+(a/g)V_2-C_{t_2}$
$R_{t_{(n-1)}} = h_{n-1}+(a/g)V_{n-1}-C_{t_{(n-1)}}$
$Z_1 = (a/g)^2S_{t_1}/[(a/g)^2+S_{t_1}F]$
$Z_2 = (a/g)^2S_{t_2}/[(a/g)^2+S_{t_2}F]$
$Z_n = (a/g)^2S_{t_n}/[(a/g)^2+S_{t_n}F]$.

Time is always to be measured from the beginning of the gate movement. Thus, the time, t_2, is the time from the beginning of the stroke to some time between the first and third intervals. The successive values of t_1, t_2, etc., must always be one interval apart.

First: Derivation of Formulas with Friction Neglected. —Joukovsky's formula for water-hammer, as already stated in Equation (1), is:

$$h = aV/g.$$

During slow closing of the gate, $dh = (a/g)dV$.

At the beginning of the closing time, as already stated in Equation (3),

$$V_0 = B_0(H_0)^{1/2}$$

and, in general,

$$V = B(H_0+h)^{1/2}.$$

For the first interval,

$$\int_0^{h_{t_1}} dh = (a/g)\int_{V_{t_1}}^{V_0} dV$$

where h_{t_1} = pressure rise at any time, t_1, during the first interval, and V_{t_1} = velocity at the time, t_1, during the first interval.

Integrating, then:—

$$h_{t_1} = (a/g)(V_0-V_{t_1}) \quad \ldots\ldots\ldots\ldots\ldots\ldots (5)$$

Since V_{t_1} must be proportional to the gate opening multiplied by the square root of the head, then, for uniform gate motion:—

$$V_{t_1} = (1-t_1/T)B_0(H_0+h_{t_1})^{1/2} \quad \ldots\ldots\ldots\ldots (6)$$

Substituting this value of V_{t_1} in the equation for h_{t_1}, the latter becomes:—

$$h_{t_1} = (a/g)V_0-(a/g)(1-t_1/T)B_0(H_0+h_{t_1})^{1/2}$$

For simplicity, substitute the symbol, R_0, in place of $(a/g)V_0$, and the symbol, $(S_{t_1})^{1/2}$, for $(a/g)(1-t_1/T)B_0$. Thus:—

$$h_{t_1} = R_0-[S_{t_1}(H_0+h_{t_1})]^{1/2}$$

Squaring:—

$$(h_{t_1}-R_0)^2 = S_{t_1}(H_0+h_{t_1})$$

Expanding:—

$$h_{t_1}^2-2h_{t_1}R_0+R_0^2 = S_{t_1}H_0+S_{t_1}h_{t_1}$$

Collecting:—

$$h_{t_1}^2-h_{t_1}(S_{t_1}+2R_0)+R_0^2-S_{t_1}H_0 = 0$$

Solving:—

$$h_{t_1} = \tfrac{1}{2}\{(S_{t_1}+2R_0)\pm[(S_{t_1}+2R_0)^2-4R_0^2+4S_{t_1}H_0]^{1/2}\}$$

Simplifying:

$$h_{t_1} = \tfrac{1}{2}\{(S_{t_1}+2R_0)\pm[S_{t_1}(S_{t_1}+4R_0+4H_0)]^{1/2}\} \quad \ldots\ldots (7)$$

For the second interval, an examination of Table 1 will show that—

$$\int_0^{h_{t_2}} dh = (a/g)\int_{V_{t_2}}^{V_1} dV+h_1-2(a/g)\int_{V_{t_1}}^{V_0} dV$$

Where h_{t_2} = pressure rise at any time, t_2, during the second interval;
V_{t_2} = velocity at the time, t_2;
V_1 = velocity at the end of the first interval;
h_1 = pressure rise at the end of the first interval;
V_{t_1} = velocity at the time, t_1, which must be exactly one interval before the time, t_2.

Integrating, then:—

$$h_{t_2} = (a/g)(V_1-V_{t_2})+h_1-2(a/g)(V_0-V_{t_1}) \quad \ldots (8)$$

Substituting C_{t_1} for $2(a/g)(V_0-V_{t_1})$,

$$h_{t_2} = (a/g)(V_1-V_{t_2})+h_1-C_{t_1}$$

Again, since V_{t_2} must be proportional to the gate opening multiplied by the square root of the head, then, for uniform gate motion:—

$$V_{t_2} = (1-t_2/T)B_0(H_0+h_{t_2})^{1/2} \quad \ldots\ldots\ldots\ldots (9)$$

Substituting this value of V_{t_2} in the equation for h_{t_2}, the latter becomes

$$h_{t_2} = (a/g)V_1-(a/g)(1-t_2/T)B_0(H_0+h_{t_2})^{1/2}+h_1-C_{t_1}.$$

Substituting the symbol, R_{t_1}, in place of $(a/g)V_1+h_1-C_{t_1}$, and the symbol, $(S_{t_2})^{1/2}$, for $(a/g)(1-t_2/T)B_0$,

$$h_{t_2} = R_{t_1}-[S_{t_2}(H_0+h_{t_2})]^{1/2}$$

Squaring:—

$$(h_{t_2}-R_{t_1})^2 = S_{t_2}(H_0+h_{t_2})$$

Expanding:—

$$h_{t_2}^2-2h_{t_2}R_{t_1}+R_{t_1}^2 = S_{t_2}H_0+S_{t_2}h_{t_2}.$$

Collecting:—

$$h_{t_2}^2-h_{t_2}(S_{t_2}+2R_t)+R_{t_1}^2-S_{t_2}H_0 = 0.$$

Solving:—

$$h_{t_2} = \tfrac{1}{2}\{(S_{t_2}+2R_{t_1})\pm[(S_{t_2}+2R_{t_1})^2-4R_{t_1}^2+4S_{t_2}H_0]^{1/2}\}$$

Simplifying:—

$$h_{t_2} = \tfrac{1}{2}\{(S_{t_2}+2R_{t_1})\pm[S_{t_2}(S_{t_2}+4R_{t_1}+4H_0)]^{1/2}\} \quad \ldots (10)$$

In a similar manner, the value of h, at any time in any interval, may be found.

(Concluded in the next issue)

Hon. A. L. Sifton, who has been Minister of Customs and Inland Revenue in the Dominion Cabinet, is relinquishing that portfolio to accept the one recently surrendered by Hon. F. B. Carvell; in other words, Mr. Sifton will be Minister of Public Works. He is a lawyer, and was formerly premier of Alberta.

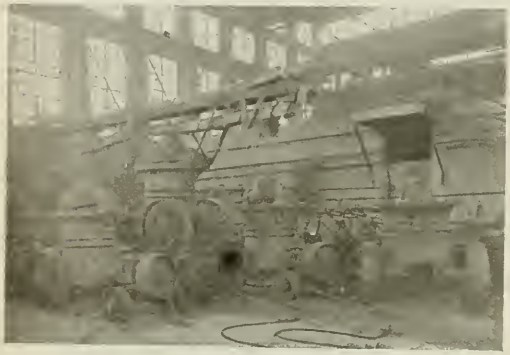
LARGE PORTABLE ROAD CRUSHERS

By R. R. Shafter
Engineer, Traylor Engineering & Mfg. Co., Allentown, Pa.

EIGHT portable gyratory crushers, believed to be the largest of their kind ever constructed, were built last year in the shops of the Traylor Engineering & Manufacturing Co., of Allentown, Pa., for the use of the American Expeditionary Force in road construction work in France.

The accompanying illustration shows some of these crushers in process of assembly in the Traylor shops. Each of the crushers weighs about 8 tons. They are made of cast steel practically throughout, in order to reduce the weight and increase the strength. They are capable of handling stone of "one man size" or up to 11 ins., and each crusher has a capacity of 25 tons of 2-in. stone per hour, with a power consumption of only 18 k.w.

The machines are of the "Bulldog" design, wherein the crusher-shaft is decidedly shorter than in the old type of



Large Portable Crushers Partly Assembled

gyratory crusher, thus decreasing the likelihood of bending or breaking the shafts.

Each crusher is mounted on a heavy set of road wheels, with a pair of front wheels under the support or outboard bearing of the countershaft of the machine. On the end of the countershaft is supplied a pulley for driving a folding elevator, which equipment was furnished with each crusher.

This type of machine proved to be a very durable, compact and economical crusher for road and general work, and on account of the extensive road building programs now under way, the Traylor Co. is preparing to add a line of these large portable crushers to the other machines which the company carries in stock.

PROPOSES DRAINAGE CANAL FOR NIAGARA

THE problem of freeing the Niagara river from sewage pollution, which still remains unsolved, although exhaustive investigation by the International Joint Commission resulted two years ago in a plan which, by reason of its heavy cost on the cities of Buffalo, the Tonawandas and Niagara Falls, as well as La Salle village, is apparently being "side-stepped" by those municipalities, was again discussed by City Engineer T. W. Barrelly, of Tonawanda, at the National City Planning Conference, held a couple of months ago in Niagara Falls.

Mr. Barrally recited the conditions affecting the situation, and found two methods of relief. They were: First, preliminary treatment of the sewage previous to its discharge into the river; second, removal of sewage by diversion to Lake Ontario.

Discussing diversion project, Mr. Barrally dismissed the proposition of an open canal along the margin of the river on account of prohibitive cost unless it were possible to take advantage of the difference in elevation of the lakes for developing water-power. A plan to construct a marginal sewer in a deep tunnel extending from the Tonawandas to Lake Ontario was advocated by the speaker.

"In making a preliminary study of the sewage disposal problem of the Niagara frontier for the pure water committee of the Tonawanda Chamber of Commerce," he said, "I have developed a plan for a marginal sewer in a deep tunnel extending from Tonawanda to Lake Ontario. There exists at the present time the old Erie canal running along the margin of the Niagara river from Buffalo to Tonawanda, and now substantially abandoned as a canal. The new barge canal route utilizes the river from Buffalo to the mouth of the Tonawanda creek at Tonawanda. At present a part of the sewage of the city of Buffalo enters the canal, including the Hertel avenue trunk sewer.

"This canal would be utilized as a drainage canal from Buffalo to Tonawanda, where it would drop about 275 ft. into the tunnel and develop water power. A similar development may be carried out at La Salle at Cayuga creek outlet. The tunnel would be about 21 miles in length and of sufficient capacity to dilute the sewage in accordance with the standards required.

"Increased dilution is secured at intervals along the route by this project and thus ample provision made to avoid the creation of nuisance along the route or at the lake. Accurate figures of cost can be made only after extensive surveys and borings and detail designs. Assuming that the tunnel is in rock, a tunnel 20 ft. in diameter could probably be constructed for $125 per ft., or a total cost of about $13,000,000 for the tunnel. Changes at the cities to make connections with the canal and tunnel for the existing sewerage systems, and power houses, machinery, etc., would cost about $7,000,000 additional, or a total of $20,000,000 for the entire project.

Water-power Development

"Assuming a diversion of 4,000 c.f.s., representing a dilution of 4 c.f.s. for each 1,000 of population, and based on a total population of 1,000,000, a head of 275 ft., and a turbine efficiency of 80%, we get a total of 100,000 h.p.

"Distributing this over the entire cost of the project, which may be as high as $20,000,000, would give a cost of $200 per horsepower.

"Since this power may be ultimately sold under a 40% load factor and to the extent of about 200,000 h.p. on this basis, we would have $100 per horsepower delivered to consumers, for the cost of the entire project.

"Probable yearly cost for power development:—

Interest on $2,000,000 at 4½%	$ 900,000
Depreciation	200,000
Other expenditures	250,000
Sinking fund @ 4%	132,000
Total	$1,482,000

"Cost per horsepower reckoned as 24-hour, seven-day power, $14.82 per horsepower per year, or if reckoned on 11 hours per week day, or under a 40% load factor, the cost would be about $7.50.

"The full income would not, of course, be attained for several years. These figures are approximate and are only given because they indicate the financial advantages possible in comparison with a sewage treatment project.

"A large part of the profit on the investment would be indirect, resulting from the more rapid growth of the cities due to power development, and consequent employment of more men and building up of industrial communities.

"This solution is attractive because it would accomplish two most desirable things, the diversion of sewage from the river and income to carry the financial burden of the project.

"Whatever method is adopted should be undertaken under state or federal regulation. It would be possible, however, to form all the municipalities and towns within the area to be served into a sanitary district, in the same manner as was adopted at Chicago in carrying out the Chicago drainage canal project."

Objections to Arthur Young Co.'s Classification

Report to Dominion Government Fails to Group Engineering Service Along Orderly Lines and Provides Too Narrow Limits for Promotion and Inadequate Compensation—Open Letter from the Chairman of U.S. Engineering Council's Committee on Classification and Compensation

SERIOUS objections are being raised by many engineers in the employ of the Dominion government to the classification and schedule of compensation recommended to the government by Arthur Young & Co., of Chicago, Toronto and New York. These objections have been well summarized in the following open letter addressed to Alfred D. Flinn, secretary of the U.S. Engineering Council, by Arthur S. Tuttle, chairman of the Engineering Council's committee on classification and compensation of engineers:—

"From time to time within the last few weeks, you have forwarded to me various letters addressed to you concerning the proposed 'Classification of the Civil Service of Canada' as recommended by Arthur Young & Co., of Chicago, Toronto and New York. The copy of this classification, which was also received, indicates that its preparation was authorized by the Canadian parliament and that the work was done under the direction of the Civil Service Commission of Canada.

"Your correspondents offer objections to the classification, particularly on the ground that the compensations proposed for higher grades of service are inadequate. In view of the investigation now being made on behalf of Engineering Council as to the classification and compensation of engineers in federal, state, municipal and railroad service, this report is of more than usual interest, and especially so since council's committee is informed that Arthur Young & Co. are performing a similar service for the U.S. congressional committee on reclassification and compensation of government employees, including engineers.

Recommend Seven Professional Divisions

"Engineering Council's committee on classification and compensation for the state and municipal services has tentatively proposed that all positions in these services be limited to 13 in number, of which 7 are distinctly professional, while the remaining 6 are in a class directly leading to professional work, but not necessarily of a professional character.

"In the questionnaire recently issued by the committee, the views of the responsible heads of the services affected are being sought, and in the responses which have been received up to the present writing, there has been practically unanimous agreement on the classification. The inquiry has not progressed far enough to warrant any expression as to the views concerning compensation other than to say that there is an unquestionably strong belief that if the engineering service is to be maintained on a proper plane, there must be a very substantial increase in pay.

No Attempt to Standardize Titles

"The Canadian report appears to cover every position in the civil service. It is arranged alphabetically, and in the absence of grouping, a complete analysis of the engineering service involves a task of magnitude greater than I have found time for. I have attempted, however, to make such examination as time permitted, and am impressed with a belief that the objections raised are well found.

"No attempt seems to have been made (by the Canadian report) to standardize titles. Consequently there are in the engineering service at least 157 independent titles as compared with the 13 titles proposed by our committee. It is recognized that qualification of a general title to show the nature of the service rendered is quite proper, but in the judgment of the writer there is no reason for treating similar positions as entirely unrelated and as warranting entirely independent specifications.

"The report states that the compensations proposed are intended for 'normal times,' and the pending restoration of such times, the rates recommended should be 'supplemented by a bonus,' but no information appears as to the magnitude of the bonus.

"From my study of the report it would appear that the groups and ranges of compensation, tabulated as far as practicable under the classification tentatively proposed by Engineering Council's committee are about as follows:—

TABULATION OF TITLES AND SALARIES FOR ENGINEERS IN CANADIAN CIVIL SERVICE REPORT UNDER CLASSIFICATION PROPOSED BY COMMITTEE OF THE U.S. ENGINEERING COUNCIL

Tentative Classification of Positions in State and Municipal Service Proposed by Engineering Council's Committee on State and Municipal Service.	No. of Titles Provided in Proposed Canadian Classification.	Salary Range Proposed for Canadian Service. Usual. Min.	Usual. Max.	Extreme. Min.	Extreme. Max.	Qualifications Proposed for Canadian Service.
Consulting Engineer	1	$6,000	.....	.....	.....	Professional Engineer, 12 years' experience (7 in charge).
Chief Engineer (major work)	5	6,000	.....	$4,800	.....	Professional Engineer, 7-12 years' experience (3 to 7 in charge).
Chief Engineer (minor work)	7	3,900	$4,800	3,600	6,000	Professional Engineer, 7-12 years' experience (3 to 7 in charge).
Chief Engineer—Deputy	8	3,900	4,800	3,600	5,700	Professional Engineer, 7-12 years' experience (3 to 7 in charge).
Engineer	37	3,300	4,020	3,000	4,500	Professional Engineer, 5-10 years' experience (2 to 5 in charge).
Senior Assistant Engineer	40	2,640	3,000	2,400	3,480	Professional Engineer, 3 years' experience (2 to 3 in charge)
Assistant Engineer	23	2,100	2,580	2,040	3,120	Professional Engineer, 3 years' experience.
Junior Assistant	15	1,680	2,040	1,680	2,160	Professional Engineer, 2 years' experience.
Senior Draftsman	..	.....	.....	Included in Professional Service.		
Draftsman	8	1,260	1,560	.....	.....	3 years' experience.
Junior Draftsman	4	900	1,200	.....	.....	2 years' experience.
Chief Instrumentman	..	.....	.....	Included in Professional Service.		
Instrumentman	5	1,260	1,560	.....	.....	3 years' experience.
Rodman	4	900	1,200	.....	.....	2 years' experience.

Sept 4, 1919

"In general, promotion through most of the grades is by increments of about $120, the minimum and maximum rates of each being respectively higher and lower than the rates fixed for the grades below and above, this resulting in a comparatively small salary range for each position, and in this respect corresponding with what seems to have been the general practice heretofore. This treatment is one which it would seem desirable to modify to the end that the relative ability and experience of men performing similar work may be given adequate recognition.

"Exceptions are noted in the case of 'Topographical Engineer,' where a salary range of from $2,160 to $3,120 is proposed, and in the case of promotion from 'Junior Electrical Engineer,' at a maximum salary of $1,980 to 'Electrical Engineer,' with a minimum salary of $2,640, each of the two latter grades having an extreme salary range of only $360. In the case of 'Chief Draftsman,' 'Structural Engineer,' and 'Chief Topographical Engineer' maximum salaries are proposed of $3,000, $3,240, and $3,840, with no provision for promotion to other engineering grades, although for each position the qualifications required are such as to indicate ability to progress to high positions in the service.

"The table also shows that only 6 engineering positions are open to compensation at a rate of more than $6,000 per annum.

"It would seem to the writer that this report is open to serious criticism on the grounds that it fails to group engineering service along orderly lines, that it provides too narrow limits for promotions within a grade, and that the compensation proposed for all grades, is inadequate for the service rendered. The latter criticism seems particularly pertinent in comparison with the rates now being demanded by organized labor. The practicability of properly meeting present-day conditions by the addition of a 'special war bonus' to the proposed rates in order to meet the present high cost of living is also to be questioned on the ground that, and as set forth in the circular letter issued by Council's committee on classification and compensation of state and municipal engineers, the 'revolutionary change in the cost of living' is one which 'unless modified by further economic disturbance is likely to be permanent or to continue for a long time to come.'"

MUNICIPAL BUREAU'S APPROVAL OF PLANS

Legislation Requiring Same is Recommended by the Ontario Municipal Association at Annual Meeting Held Last Week in Toronto—Other Resolutions Adopted

At the annual meeting of the Ontario Municipal Association, held last week in Toronto, a number of resolutions were adopted, and the executive committee was requested to prepare bills, embodying the spirit of the resolutions, for presentation to the Ontario legislature. Among the resolutions were the following:—

(1)—Whereas municipalities are, from time to time, called upon to undertake municipal works which demand high-priced expert skill and experience; and whereas the financial standing of many municipalities require careful and conservative consideration when large expenditures are involved; therefore resolved,—that all by-laws, plans and specifications providing for the construction of permanent improvements and the issue of debentures therefor, should be approved by the municipal bureau.

(2)—That the legislature of Ontario, and the department of highways, be respectfully requested to enact such legislation as will provide for the standardizing and erection of danger signals on roads and highways throughout the province.

(3)—That the Dominion Railway Board provide that at points where gongs are used, or are necessary as warning at railway crossings, these said gongs be placed at both sides of the said railway crossings, on the highway, at a distance of not less than 50 ft. from the railway.

(4)—That rural municipalities be granted the power now enjoyed by urban municipalities of regulating the opening of sand and gravel pits and the removal of sand and gravel from pits already in operation.

(5)—Whereas dissatisfaction has been expressed by citizens with the present form of municipal government; and whereas more centralized control of all civic activities by one governing body is desired, either by what is commonly called commission government or by some method of co-ordinating the existing councils, boards and commissions; be it resolved that the provincial legislature be petitioned to secure a report on improvement of the present municipal government system which will best conform to Ontario ideals of government and satisfy modern demands.

EDUCATION OF HIGHWAY ENGINEERS

By Arthur H. Blanchard
Professor of Highway Engineering, University of Michigan

Highway officials, progressive educators and many prominent business men realize that a serious condition will confront the United States and Canada if graduates of our technical schools are not properly trained in highway engineering. The phenominal development of highway transport has created a demand for efficient highway improvement which can only be satisfied by placing highway work in the hands of competent engineers.

Thoroughly trained and experienced highway engineers are needed to occupy the innumerable positions connected with the administration, financing, design, construction and maintenance of the 2,500,000 miles of rural highways and the thousands of miles of streets in the municipalities of the United States and Canada in order that highways may efficiently serve economic, social, transportation, agricultural, industrial, commercial and military requirements. Highway appropriations will increase rapidly during the next five years, as is indicated by the 1919 appropriations of $500,000,000 in the United States and a relatively large amount in Canada, for highway improvements, and a wide-spread demand for the construction of a system of 50,000 miles of national highways by the United States government under the direction of a national highway commission.

Estimates made this year by the United States Bureau of Public Roads disclosed a remarkable field of opportunity for highway engineers, as investigation showed that for federal and state highway work alone, exclusive of cities, counties and towns, there are required 122 chief executives and administrators; 360 division engineers of the federal government, division chiefs of bureaus, division chiefs of highway departments, district engineers of highway departments, etc.; 3,630 supervising engineers and chiefs of party; and 6,350 junior engineers, rodmen, chainmen, draftsmen and others.

The consensus of opinion of eminent highway engineers and educators is to the effect that highway engineers should have the broad foundation which the four-year course in civil engineering gives. The Asphalt Association takes the definite stand that as much time should be given to the essentials of highway engineers as is given to sanitary, hydraulic or railroad engineering. The association will devote its educational campaign especially to institutions where either no courses or very short courses in highway engineering are given. The Asphalt Association has found that only 25 of the 93 colleges investigated give a satisfactory fundamental training in highway engineering as a part of the civil engineering course.

The waste of millions of dollars annually in the United States will continue until the profession of highway engineering is placed on the same basis as structural, hydraulic, sanitary and other branches of civil engineering. England and France have seen the light. As a result, efficient highway engineers are retained in office, methods of construction and maintenance suitable for traffic requirements are employed, and as a consequence the public funds are wisely and economically expended.

CONCRETE RAILWAY TRACK SUPPORT

VARIOUS types of concrete track construction that have been installed on United States railways were described by A. C. Irwin, engineer of the Structural Bureau of the Portland Cement Association, in a paper recently presented before the American Concrete Institute. The following excerpts are from Mr. Irwin's paper:—

Street Car Track Construction at Anderson, S.C.—A type of track construction designed by E. R. Horton, Jr., and used in Anderson and Greenville, S.C., for street car track construction is shown in Fig. 1. This is in reality the longitudinal girder principle. The rails are embedded in the concrete and rest on a continuous plate. Rail clips and hook bolt anchors are used.

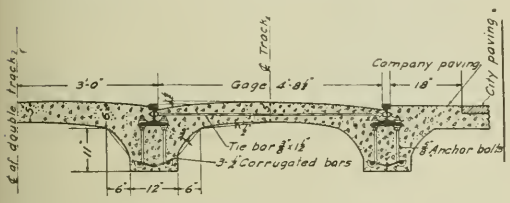


FIG. 1—CONCRETE STREET RAILWAY TRACK CONSTRUCTION AT ANDERSON, N.C.

Recent inquiry in regard to the condition of this track after four years' service indicated that the construction has been found satisfactory in every particular, that vibration has not caused deterioration of the concrete and that even the paving between the tracks is in good condition. To adapt this design to steam railroad requirements, states Mr. Irwin, it would only be necessary to deepen the girders and widen them out at the base for additional bearing area and to change the paving in between tracks to diaphragms at intervals below the base of rails.

Installation on Long Island R.R. at Jamaica, N.Y.—Examples of the type involving a concrete slab carrying ballast in which ordinary track ties are embedded is shown by Fig. 2. This construction was placed under 49 crossings, switches and slips on the Long Island R.R. at Jamaica, N.Y. The work was put in during the winter of 1912-13 on embankments composed of sand averaging 20 ft. high. Portions of the slabs were placed without allowing time for the embankment to settle and the traffic over these slabs has been extremely heavy from the day they were put in, running as high as 1,300 train movements per day. After 3½ years the general manager of the Long Island R.R., J. A. McCrea, reported that there had been practically no maintenance on the track. Mr. McCrea goes on to say that the great advantage of the slab is that the bearing surface on the natural ground is increased about three times over the usual method without taking into consideration its continuity and that examination of these experimental slabs showed that there

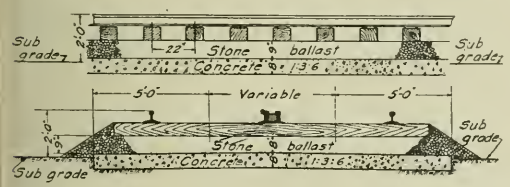

FIG. 2—SECTION OF CONCRETE SLAB, JAMAICA IMPROVEMENT, LONG ISLAND, R.R.

were no cracks, at least in the vicinity of the points of examination. It will be noted that these slabs are not reinforced and that they are only 8 in. thick. It should also be noted that they have been subjected to the pounding that occurs at crossings and frogs.

It has become very common practice to use reinforced concrete slabs to form the decks of deck girder railroad bridges. These slabs are usually about 1 ft. thick, 5 ft. long and span the distance between girders. The ballast is retained by curbs at the ends of the slabs. The testimony of railroad officials in regard to this construction is that when

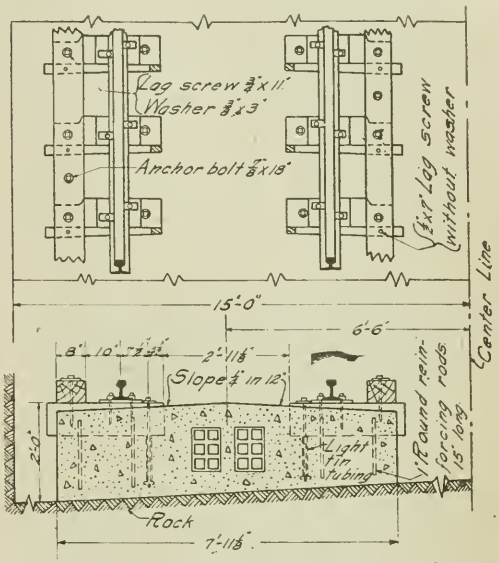

FIG. 3—CONCRETE TRACK CONSTRUCTION USED IN BERGEN HILL TUNNEL OF D.L. & W. RY.

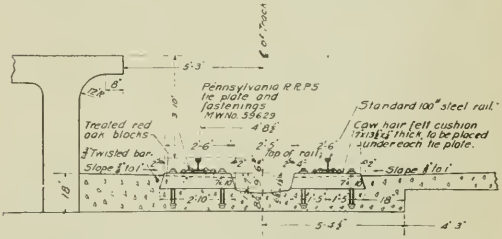
the ties are once embedded they stay in place and that maintenance is very greatly reduced.

Bergen Hill Tunnel Tracks, Delaware, Lackawanna & Western R.R.—The new Bergen Hill Tunnel of the D., L. & W.R.R. was completed in 1909. The tracks in this tunnel are carried on reinforced concrete slabs, details of which are shown in Fig. 3. This construction was designed by Lincoln Bush, who was then chief engineer of the railroad.



Pennsylvania R.R. P.S. tie plate and fastenings Wrot. Iron 5⅜x29
Standard 100# steel rail
Treated red oak blocks
Cow hair felt cushion 1"x3½" thick, to be placed under each tie plate.

5'-5½"
4'-3"

FIG. 4—CONCRETE TRACK CONSTRUCTION AT PENNSYLVANIA TERMINAL, NEW YORK

Under date of October 3, 1916, Mr. Bush reported as follows in regard to this construction:—

"It was completed and turned over for service in February, 1909. The roadbed in the new tunnel has stood up exceedingly well and none of the creosoted tie blocks have been renewed so far as I have learned on recent inquiry.

"My idea in getting out this design was that if railroad track could be made perfectly rigid and unyielding, there would be no pounding or unusual stress in rail. The roadbed in the new tunnel referred to has been in service under the heaviest kind of traffic since February, 1909, and

has demonstrated fully that if track is made perfectly rigid that it will stand up against the heaviest kind of traffic.

"I am convinced that with a perfectly rigid surface there will be no pounding and serious damage in railroad track unless some defect existed such as flat wheels. Such conditions, however, are corrected when they do arise with the railroad rolling stock. I have felt for some time that with the heavy rolling stock that the best ballasted track had practically reached the limit of loading and if the heavy rail is used the supports of same on tie ballasted track is not like the abutment of a bridge as ties yield causing deflections in the rails and it will be found that even with a heavier rail the stress may be greater in the rail than with a light and less stiff rail section which lends itself more readily to deflection."

The tie blocks are notched at the outer end to form a shoulder and are in place when the concrete is poured. A wedge is driven in between the concrete and the opposite side of the block, preventing the block from being disengaged from the shoulder under traffic. The blocks are replaced by moving the wedge, pushing the block longitudinal

FIG. 5—CONCRETE TRACK CONSTRUCTION ON CHICAGO JUNCTION RY.

of the track so as to disengage the shoulder and slipping it from under the rail. This work can be done by one man.

Track Construction in Pennsylvania R.R. Terminal Station, New York.—Fig. 4 shows the concrete track construction in use in the Pennsylvania R.R. terminal station, New York. A single track length of 14,600 ft. of this type was laid adjacent to platforms. In general the concrete was laid on the rock of the subgrade, but where the subgrade consisted of loose rock backfilling the concrete slab was reinforced. A length of 720 ft. of similar construction is in use in two of the East River tunnels (Nos. 1 and 2) immediately east of the Long Island shafts. These sections of track are subjected to high-speed traffic.

The Chicago Junction Ry. Track.—In 1911, 500 ft. of concrete track support was installed on the Campbell Ave. line of the Chicago Junction Ry., where it crosses the Illinois and Michigan Canal. Details of this construction are shown by Fig. 5. This construction is patented by Louis H. Evans, of Chicago, and was installed on the Chicago Junction Ry. as an experimental stretch of track, the location being se-

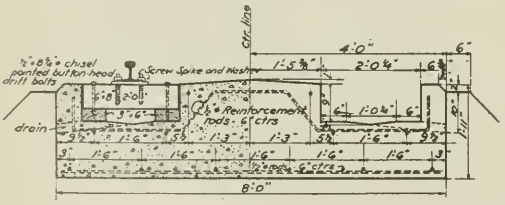

FIG. 6—TYPE 1 OF NORTHERN PACIFIC RY. CONCRETE FOUNDATION

lected with a view to subjecting it to very heavy and continuous traffic. A majority of the stock trains going to the Chicago Stock Yards pass over this concrete track. These trains are usually drawn by heavy locomotives and make more than usual freight train speed. A thorough examination of the track indicates that although transverse cracks appear in the portion of the concrete above the base of rails, these cracks do not extend down into the supporting slab. In fact, the construction seems to have suffered practically not at all from the heavy traffic which it has carried. G. W. Hegel, chief engineer, the Chicago Junction Ry., advises that there has been no maintenance on this stretch of track excepting to renew a few of the tie blocks. The tie blocks are spaced 34 in. centres. So great a spacing would not be allowed with the usual ballast and tie type of con-

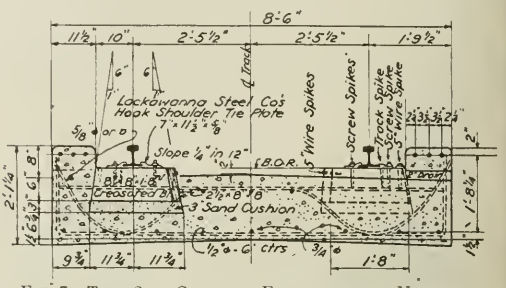

FIG. 7—TYPE 2 OF CONCRETE FOUNDATION ON NORTHERN PACIFIC RY.

struction, but with this unyielding track foundation such a spacing has been found to be practicable, since the majority of the deflection in railroad track is due not to the lack of rail stiffness but rather to the lack of any sort of rigid support. Mr. Evans sums up the comparison of this construction with the usual type as follows: Weight of train distributed over 3 times the surface saves $\frac{9}{10}$ of the ties. The cost for 20 years is one-fourth of rock ballasted track.

Northern Pacific Ry. Track.—On the Point Defiance Line of the Northern Pacific Ry., in the State of Washington, there was constructed about five years ago, 2,000 ft. of track with a concrete slab foundation. Details of the three types used are shown by Figs. 6, 7 and 8. In general, these types consist of a reinforced concrete slab provided with recesses or troughs for the reception of wood blocks or stringers to carry the rails. Details of Type No. 1 are shown by Fig. 6.

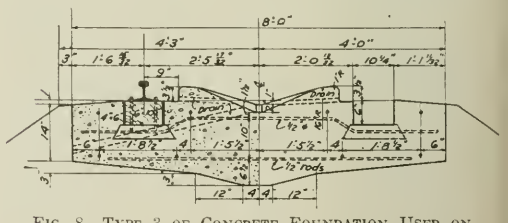

FIG. 8—TYPE 3 OF CONCRETE FOUNDATION USED ON NORTHERN PACIFIC RY.

The short tie blocks rest on two longitudinal 3 by 6 pieces in the bottom of a trough at each side of the slab. The space in between tie blocks is filled with ballast. Drainage of the troughs is provided at intervals. There is a total of 594 ft. of Type 1 construction. The slabs are cast in lengths 16 ft. 5½ ins.

Type No. 2, Fig 7, is 6 ins. wider than Type No. 1 or No. 3, and is distinguished by a curb practically equal to height of rail along each side. There is also 594 ft. of single track of this type in service. In this type recesses are cast into the slab into which the tie blocks are placed and wedged into position. The rails are fastened in the usual way with tie plates and screw spikes. In the bottoms of the tie block recesses 3 ins. of sand is placed to afford a cushion. On top of this sand cushion the creosoted tie block is placed and wedged at the inner end of the block. L-shaped malleable shims are used at the other end of the tie blocks with one leg of the L resting on top of and fastened to the tie block. This allows lining and gauging of track. These slabs are cast in widths of 32 ft. 11 ins.

Type No. 3 is shown in detail on Fig. 8. The distinguishing features of this type are that the concrete is carried up 3½ ins. near the inside of each rail and sloped to centre of track for drainage, and that the rail rests directly on a continuous longitudinal stringer of 6 by 10 ins. creosoted fir. These stringers are fastened at intervals by long lag screws driven into wood anchor blocks embedded in the slab. The slabs have a depth of 18 ins. at the centre and were moulded in lengths of 16 ft. 5½ ins. There is a total of 810 ft. single track of Type 3.

While neither the first cost of the concrete track foundation on the Northern Pacific R.R nor the annual maintenance cost of it are available, yet the railroad company's officials say that the maintenance has been far below that of track of the ordinary type of construction on the same line. The greater part of this maintenance concerns the wooden blocks to which the rails are fastened, especially with Type 3. In

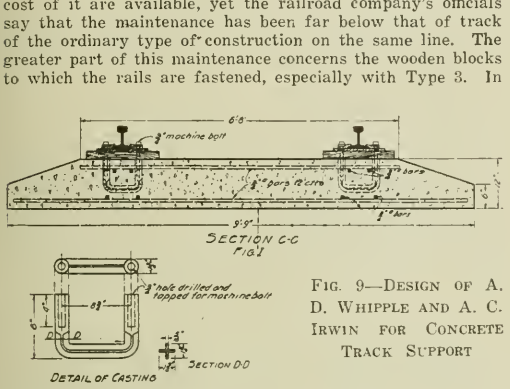

FIG. 9—DESIGN OF A. D. WHIPPLE AND A. C. IRWIN FOR CONCRETE TRACK SUPPORT

this type the key blocks out in spite of the fact that they are spiked to the tie blocks.

New Design for Concrete Track Support.—Fig. 9 shows a suggested design for concrete track support prepared by A. D. Whipple and A. C. Irwin. The form work required for this slab is of the simplest sort. The design of the slab is based on Cooper's E-60 loading with 100 per cent. impact. This design does not require any radical departure from the usual type of rail fastenings, that is, a rail clip is used similar to those now standard. There is, however, a very great difference between this rail fastening and the usual cut or screw-spike used with wooden ties. In this concrete design a U-shaped casting is embedded in the concrete and the upstanding legs of the U are tapped to receive the threaded end of holding down bolts which pass through the rail clips, tie plate and tie block. A positive fastening which has great strength against lifting the rail is thus secured. The use of a block of wood under the rail in this design is at once a concession to the prevalent idea that some elastic medium must always intervene between a track rail and a solid foundation and a means for easy adjustments of the rail both vertically and horizontally to provide for whatever inequalities may exist in the top of the slab either at the time of placing or subsequent thereto. The latter is the only sufficient reason for using this tie block, and where the slab is placed on a well compacted subgrade the rail may be anchored directly to the concrete, with possibly the intervention of a longitudinal steel plate between the rail and the concrete surface, thus affording the rail a continuous support. In the latter case drainage would be taken care of by finishing the slab to a slight pitch between the rails and furnishing openings beneath the rails at intervals.

City Commissioner Mackie, of Moose Jaw, Sask., has prepared a statement showing the operation of the Light and Power Department and the Water Works Department for the first six months of this year. The Light and Power deficit was $200.70 and the Water Works deficit, $1,444.94. At the beginning of the year Mr. Mackie had estimated that the Light and Power Department would just about pay its own way for the ensuing six months and that the Water Works deficit would be over $9,000.

FINE-GRAINED CONCRETE SANDS

By F. E. Giesecke
Professor of Architectural Engineering, University of Texas

THE engineering division of the University of Texas is planning a systematic study of sands with reference to their value in concrete construction, because we believe that there are many deposits of fine-grained sands which are generally considered too poor to be used in concrete construction and which have to be rejected under most specifications in force at the present time, but which, with proper care, might possibly be used to advantage, thereby saving considerable sums of money. We were led to this conclusion by a consideration of the following:—

We have a considerable quantity of an extremely fine-grained sand to be tested; the sand has the following sieve analysis:—

Retained on 200-mesh sieve	78.0%
Retained on 100-mesh sieve	43.0%
Retained on 65-mesh sieve	4.8%
Retained on 48-mesh sieve	3.0%
Retained on 35-mesh sieve	None

Among the current specifications for concrete sand are the following:—

(A)—Sand shall grade from fine to coarse; all shall pass the ¼-in. sieve; not more than 28% shall pass the 50-mesh sieve, and not more than 10% the 100-mesh sieve.

(B)—All sand shall pass the ¼-in. sieve; not more than 75% and not less than 40% shall pass the 20-mesh sieve; not more than 30% and not less than 2% shall pass the 50-mesh sieve; not more than 6% shall pass the 100-mesh sieve.

(C)—At seven days a 1: 3 mortar should have a strength at least equal to that of Ottawa sand mortar; the sand shall be rejected if the strength is less than 70% of that of the Ottawa sand mortar.

The sand referred to would therefore have to be rejected under specifications A and B; it would also have to be rejected under specification C, because when tested in mortar it developed a tensile strength of 200 lbs. per sq. in. at seven days in a 1: 3 mortar as against a strength of 293 lbs. for Ottawa sand mortar.

It may be of interest to note that this sand has a "fineness modulus" of 0.46 according to the system proposed by the Lewis Institute of Chicago, and that Bulletin No. 1, issued by the Lewis Institute in April, 1919, suggests on page 12 that "sand with a fineness modulus lower than 1.50 is undesirable as a fine aggregate in ordinary concrete mixes. Natural sands of such fineness are seldom found." So the sand also fails to meet the requirements proposed by the Lewis Institute.

In spite of the fact that the sand failed to pass any of the current specifications, concrete made with the same was fairly good, as will be seen from the following:—

The concrete was made up with a blend cement and with Colorado river gravel carefully screened and rescreened so as to contain no material finer than ¼-in., and in the following proportions:—

Blend cement	14.3%
Fine grained sand	14.3%
Gravel, ¼ to ¾ in.	35.7%
Gravel, ¾ to 1¼ ins.	35.7%
	100.0%
Water	11%

The resulting mix had a thick, flowing consistency. The following unit strengths were found at an age of 28 days in 6 by 12-in. cylinders:—

Rodded eight times, 30-minute intervals	3,420
Rodded eight times, 30-minute intervals	3,240
Rodded eight times, 30-minute intervals	3,110
Rodded only slightly just after moulds were filled	2,530
Rodded only slightly just after moulds were filled	2,500
Rodded only slightly just after moulds were filled	2,440

(By "rodding" concrete we mean pushing a pointed iron rod into the concrete to allow the excess water and the entrapped air to escape upward and to compact the aggregate. See article in the August 14th, 1919, issue of *The Canadian Engineer*, page 217.)

The above-mentioned strengths compare favorably with those of other concretes: for example:—

Compared with the Lewis Institute expression for the strength of concrete ($14{,}000 \div 7^{\frac{5}{8}}$), this concrete should have a strength of about 1,500; it is apparent that the three rodded specimens were about 117% stronger and the three plain specimens about 65% stronger.

Compared with the best concrete prepared in our laboratory with carefully graded Colorado river sand and gravel and with the same percentage of cement (about six sacks per cu. yd.) and thoroughly rodded, which developed a unit strength of about 4,700 lbs. per sq. in., this concrete was about 69% as strong.

Compared with concrete recently used in a reinforced concrete building, and prepared of good materials under specifications calling for a 1:1½:3 and a 1:2:4 mix, and developing the following strengths in 28 days: Plain concrete, 1,568 and 1,208 lbs. respectively; thoroughly rodded concrete, 2,293 and 2,215 lbs. respectively, this concrete is about 50% stronger.

We wish it understood in this connection that we are not advocating the use of such extremely fine sand in concrete construction, but we believe that there are many deposits of sands which are too fine to pass current specifications and yet sufficiently coarse to produce good concrete if used in the best possible manner, thereby saving considerable sums of money in concrete construction near such deposits, and that this subject deserves careful investigation.

Your attention is invited to the fact that the mix described above was about a 1:1:5 mix and it may not be amiss here to call attention to the common but erroneous belief that a 1:2:4 mix will always produce good concrete.

According to Fuller's maximum density curve, a 1:2:4 mix is good when the fine aggregate grades from very fine to ¼-in., and when the coarse aggregate grades from ¼-in. to 1¼ ins.; when either the fine or the coarse aggregate grades differently, a mix other than 1:2:4 should be used for 1:6 concrete.

INCREASE OF RAILWAY MILEAGE SINCE 1835

THE history of railway mileage in Canada, less trackage rights, is brought to the year 1918 in the following table, taken from the report of Railway Statistics for the year ended June 30th, 1918, issued by the Department of Railways and Canals:—

Year.	Miles in operation.	Year.	Miles in operation.
1835	0	1868	2,270
1836	16	1873	3,832
1846	16	1878	6,226
1847	54	1883	9,577
1850	66	1888	12,163
1851	159	1893	15,005
1852	205	1898	16,870
1852	506	1903	18,988
1854	764	1908	22,966

T. Kennard Thomson, of New York City, who is a well-known consulting engineer and a graduate of the University of Toronto, has planned a six-track belt line railway to run around Manhattan Island, at a cost of $250,000,000. Mr. Thomson states that 200 business men are willing to finance the work at no cost to the city.

NEW STONE AND GRAVEL ROADS INSURED BY SURFACE TREATMENT

By F. H. Gilpin
Engineer, Asphalt Sales Department, The Texas Co.

EVERY form of construction dedicated to public use and comfort bears some type of insurance against its own particular agent of destruction, except those means of communication which are open to the free and unlimited use of all—our highways and by-ways. Whether it be a main artery of travel between large centres of industry, or a minor capillary sufficient for the needs of a small community, some insurance should be created to ensure to all a longer, useful life of these means of communication upon whose very existence is dependent the life, health and happiness of the inhabitants.

Particularly the minor arteries are of interest, as, in reflection of a universal demand for permanent lines of communication, a program of construction has been evolved that will in a few years bind the main centres with roads that will carry practically unlimited traffic. Available funds do not permit, nor does reason demand, that all lines of communication be so established. Already by far the greater mileage of our secondary roads are being subjected to a class and amount of traffic far beyond that which they were intended to withstand; and besides, the public demands that they be maintained and insured against the future destruction.

Destructive Forces

How do the main forces of destruction act, and how should they be insured against? Primarily, through the erosion of the surface by the forces of nature and traffic; secondarily, by the destruction of the wearing course, and finally, the destruction of the base through the same agencies aided in increasing ratio as the avenues of attack are opened. How can these agencies of destruction best be insured against? By the creation of a greater bond in the surface that at the same time renders it more tenacious, adherent, resilient and waterproof.

This is attempted in many ways: By the use of water, solutions of various chemicals, deliquescent salts, paraffine base oils, tar distillates and asphalt base oils.

What are the merits of the various means? Water obviously is temporary in character and requires repeated applications, in some cases many times daily. Deliquescent salts are dry weather remedies, and their very nature tends to wash them out in heavy rains. The same argument applies to chemical solutions. Paraffine base oils are more or less odorless and colorless but their lack of binding qualities and tendency to run off the road and be washed off by heavy rains, place them in a class useful only as temporary dust layers requiring duplication of seasonal routine.

Tar distillates are the first that come within the class that in addition to dust laying, form a waterproofing adhesive mat on the surface of the road, and, being marketed in various grades, permit of several degrees of intensity of application, both with or without prior heating.

Asphaltic Oils

Asphaltic oils permit of a wider range of surface treatment than any other type of material for this purpose. Having a minimum susceptibility to temperature change, the protective coating formed does not become brittle in cold weather nor too soft in hot, thus ensuring a waterproof, resilient surface throughout the year. Available in all grades from a light dust-laying material to the heaviest which requires both heat and pressure for application, practically any type of road from earth to new macadam can be protected against erosion and made to render a longer serviceable life to the property owner and the user.

The more open the surface of the road, the more recent the construction, the greater is the ability of the road to take a heavier surface treatment with consequent increased length of time between applications and satisfactory results. Oiling a road will not restore an eroded surface, nor will it re-establish a destroyed crown, but where the surface is not badly worn, a treatment with a hot application

and clean stone screenings or slag grit will re-establish a wearing surface which will withstand moderate traffic for several years.

Don't Wait Too Long

The fact that a road is newly constructed and needs no repairs should be only an added incentive to protect the surface before the forces of destruction have full sway and put the road into such a condition that oiling of the surface preserves only the portions that remain intact, and permits the impact of heavy moving vehicles to enlarge any potholes or depressions, so that the effect of the oiling becomes nullified. The success will be no greater than that of trying to stop holes in a roof caused by dry rot or physical damage, by painting the remaining surface. The time to oil is now, before destruction starts, and repeat the treatment, according to the intensity desired, as required, successive treatments decreasing in intensity.

As in any material application, the best material applied to the purpose at hand in the most skilful and careful manner, gives the best appearance and the most lasting qualities. Oil that requires a small amount of heat to permit the most efficient operation of a pressure distributor, applied to a thoroughly clean, swept road, and covered with sufficient gravel or screenings to completely cover the surface immediately after application, has given complete protection against excessive rainfall by which untreated roads have been partially destroyed.

Objections Temporary

Objections as to odor and color of asphaltic oils are temporary and personal. The odor is slight at any time, and vanishes as the road dries. The color can only be objected to when tracked into the residences of the property-owners, and any oil (if of value as a binder), if permitted to adhere to other objects, will form a nucleous around which the objectionable particles of dirt will collect, whether the oil possesses a color or not.

At seashore or other resorts where unpleasant, personal contact with the new surface is an obvious objection, treatment early in the year would permit a finished surface to be presented during the season and would meet with the approval of all.

Where the road surface is of a material that is finely divided and does not permit of sweeping, oil containing a minimum of asphalt, lightly applied, will allay the dust for a season, though the protection against such traffic as a road so constructed should be called upon to stand is more nominal than real. The small degree of porosity and close formation of the surface prevents the absorption of any binder except such as can be carried by the lighter carrier in the oil.

As the character of the surface of the road changes so that a heavier oil can be applied, two light applications in a season permit a rapid drying of the surface and a penetration of the asphalt sufficient to reduce, to a negligible amount, the ability of traffic to pick up the oil.

HIGHWAY TRAFFIC REGULATIONS

SUGGESTED general highway traffic regulaions, accompanied by an interpretative bulletin, are now being sent out by the tens of thousands as a part of the campaign inaugurated by the U.S. Council of National Defense through its Highways Transport Committee, to the end that the number of accidents on the highways be decreased.

Police records, it is said, especially in recent months, emphasize the vital need for concerted action looking to the safety of life and limb, and intelligent study along the lines of simple and easily understood highway regulations.

The view of experts who have given the subject of traffic regulations extended study is that uniformity, especially as to the fundamentals in traffic regulation, is necessary if success in combatting this evil is to be in proportion to the need for the same.

The Council of National Defense believes it is possible, through the adoption very generally by municipalities of the suggested regulations which it is distributing to the public, to reduce to a most gratifying extent the number of accidents growing out of the rapidly increasing number of motor vehicles on the highways.

The key to the solution of the problem of how best to protect those travelling on the highways, especially in the cities and towns, both pedestrians and drivers of vehicles, says the council, is through education of the public. Once the standardization of highway traffic regulations is brought about through co-operation by authorities in the principal cities of the country, this education of the public as to the need for observation of rules laid down in these regulations, it is believed, may fairly quickly be brought about.

The regulations being distributed by the Council through its Highways Transport Committee stress the necessity for caution being exercised at crossings, roadway intersections and junctions, where most accidents occur. This caution implies extreme care on the part of drivers and constant watchfulness upon the part of both drivers and pedestrians.

MONTREAL AQUEDUCT ARBITRATION

City Must Pay $308,000 to the Cook Construction Co., Who Claimed $1,775,000—Company Is Held Responsible for the Break in the Concrete Conduit

CLAIMS aggregating $438,000 have been allowed against the city of Montreal by the award of the Board of Arbitration in the suit for $1,775,000 brought against the city by the Cook Construction Co. as damages for the cancellation of the aqueduct contract. Counter-claims to the amount of $130,000 were conceded by the board, leaving a balance of $308,000 to be paid by the city to the construction company.

The arbitrators were W. F. Tye, consulting engineer, Montreal; J. M. R. Fairbairn, chief engineer of the C.P.R.; and Aimé Geoffrion, K.C., Montreal.

The company originally claimed $1,900,000 and the city claimed $50,000, but these amounts were later reduced respectively to $1,775,000 and $412,000.

A feature of the arbitrators' judgment is that the Cook Construction Co. is held responsible for the break in the conduit, December 25th, 1913, when most of the people of Montreal were deprived of water for several days. On this account the city was awarded $81,889 as compensation for lack of precaution by the company.

In this portion of the award Mr. Tye dissented, but Messrs. Fairbairn and Geoffrion were of the opinion that the company is liable for the reason that it had been emphasized in the contract that the conduit was the sole source of water supply for the greater portion of the city of Montreal, and that extreme precaution would be required in connection with it, and that the contractor would be held responsible if he were to damage it.

Mr. Tye dissented on the ground that the city engineers had misled the company in regard to the reinforcement of the conduit, the tamping of the backfill, and the underdrain, and because the city had not informed the company of a washout that had occurred before the signing of the contract.

The largest individual item of damages awarded to the company was on account of delays. The amount claimed under this head was $600,000; the amount awarded was $215,881.

The agreement to arbitrate the differences between the company and the city was made nearly two years ago, and since then witnesses and experts galore have been called to enlighten the arbitrators regarding the responsibility for one of the biggest municipal tangles in which Montreal has ever become involved.

According to the terms of the arbitration, each party pays its own costs for legal advice and witnesses, while all other costs are equally divided.

PROBLEMS CONFRONTING MUNICIPAL ENGINEERS*

By Charles Brownridge
Borough Engineer, Birkenhead, Eng.

With the conclusion of the war there is much leeway to be made up, and arrears to be made good, and it is very desirable that—having regard to the altered conditions which now exist—we should closely consider how we can in future best plan and carry out our work, and what improvements in our methods we can with advantage adopt.

In work connected with the war, all branches of science were organized for one common aim, and I would express a hope that this principle should not be altogether abandoned, but that the system should, at least in part, be retained and continued, with its energies directed now to investigation and research for the improvement of the health and welfare of the community, and that the State should, either by direct action or generous subsidy to the laboratories of the various universities, foster and encourage experiment and research in order to ascertain the best methods and appliances to adopt to prevent and stamp out disease, and to discover new, and improve existing, materials and methods used in construction work.

The Supply of Materials

With reference to materials, we have in the past, while endeavoring to do our best with those to hand, been too content to accept the materials available. I feel sure that if the energy and ability of our chemists were directed in the right channels, they would be able to give us many improved and alternative materials suitable for our work, and devise methods to increase production and cheapen the cost of manufacturing or producing existing materials.

As engineers we would welcome the discovery of a cement having the combined merits of portland cement and bitumen, and satisfactory substitutes for wood, stone and bricks. I feel sure that, although the bricks at present manufactured are excellent, cheaper methods of manufacturing and burning could be devised.

Any and all efforts to ensure good buildings being erected and new work carried out at a reasonable cost will be to the material advantage of the State, and enable us to carry out more quickly the many and various works that are so urgently required, and so necessary in connection with our municipal work, to make our people healthy, and to keep them healthy and happy in the future.

The past has taught us many lessons from which we should now profit, and we should now, by taking a wide and generous view, so shape and design our work as to look well ahead and not only provide for the present, but have due regard to the changing conditions now existing and the consequent probable requirements of the future.

Labor Difficulties

The wave of industrial unrest now passing over the country is seriously affecting the work of our municipalities, and it will be necessary that we should carefully consider and review the position with a view to best overcoming the serious labor shortage existing, and adapting our conditions to meet the higher wages now ruling.

It is to be regretted that workmen, whilst justly and properly taking all means to assert their rights, do not in very many instances appreciate that they have in addition also their duties to themselves, their families, their work and to the State.

Good wages can always be justified if supported by good labor, but the present irregular time-keeping of many of our workmen is causing serious unnecessary difficulties and waste to arise. In my own case, I regret to say that since armistice day there has been amongst the men employed under my direction an average daily absenteeism exceeding 10 per cent., often causing necessary sanitary duties to be seriously prejudiced and affected. Unfortunately, this irregularity not only affects the work which should be done by those absenting themselves, but in many instances disorganizes and interferes with the arrangements necessary to be made in connection with all work, and causes serious loss and waste of time. If any steps can be taken to stabilize labor and make its service dependable—subject, of course, to justifiable absence owing to sickness—it would, I am sure, be welcomed by all having the charge and direction of work.

Use of Machinery Necessary

It will be necessary on financial grounds for the engineer carefully to consider what machinery and appliances can be installed to cheapen and expedite work, and to foster and further the employment of mechanical appliances for all work in which it is possible for it to be suitably and beneficially used, especially that which will tend to reduce the employment of unskilled labor, as, with the universal advance in education and learning, this branch of labor should be reduced to a minimum and its present members transferred to and trained in some branch of the arts and crafts.

The extent and character of the use of machinery in our work in future will no doubt be considerable, and its form and design offer a wide field to the ingenuity of the inventor, and, as progressive engineers, we should do all we possibly can to further its application and foster its invention. Most municipalities have already found it both economical and advisable to adopt mechanical haulage, and are considering the introduction of machines for the combined sweeping and collecting of refuse from the streets, and for excavating, filling and ramming trenches; a more extended use of mechanical mixers for concrete and tar-macadam; a more general adoption of mechanical means for lighting and extinguishing lamps and other numerous mechanical devices will be found necessary and desirable.

Institution Sparing no Efforts

The work of the municipal engineer is most wide in its scope, of a most varied character, and its duties onerous, calling for unremitting attention, care and thought, and it is therefore fitting that the Institution of Municipal and County Engineers are sparing no efforts to ensure that its younger members shall be properly educated and trained for their work, and have every facility for this purpose, and further to ensure that local authorities should only appoint properly trained engineers and surveyors at a proper and adequate salary; and, having regard to the great effect the work of the engineer and his assistants has on the prevention of disease and the comfort and health of the community, this excellent work will no doubt bear good and valuable fruit and enable the members of our profession to direct their endeavors in the most effective and productive way to carry on their duties.

*Excerpts from presidential address delivered before a Conference of Engineers and Surveyors held in connection with the Royal Sanitary Institute Congress at Newcastle-on-Tyne, Eng.

For five hours last evening, Toronto was without street car service, as 250 electrical workers of the Toronto Power Co. went on strike and stayed out until Manager R. J. Fleming wrote a letter to Mayor Church accepting, in its entirety, the report that had been made by a Board of Conciliation. The strike was unexpected and many street cars were stalled, unlighted, at street intersections.

The "Review of the Foreign Press," which has been published fortnightly for the past 2½ years by the General Staff of the War Office, London, Eng., has been discontinued, the last number appearing August 19th, 1919. Major Simnett, the editor, says: "Having regard to the cessation of war, it is obviously inappropriate that this work should be conducted under the auspices of the General Staff."

The Consolidated Iron and Steel Corporation, Ltd., has been incorporated with offices in Toronto. The company's officials state that the company owns two large deposits of iron ore lands, one of which is at mileage 182 of the Algoma Central Railway, and the other consists of 1,500 acres in the county of Leeds, Ontario, 25 miles north of Brockville. It is stated that the city of Brockville has offered inducements to the company to build a smelter there.

HIGH CONTRACT PRICES SHOULD LEAD NEITHER TO POSTPONEMENT NOR TO DAY LABOR*

IT is difficult to realize that the cost of road and street construction has doubled in five years. Consequently, when contractors bid twcie as high as in 1914, there is a strong inclination to reject all bids. In some cases this leads to postponement of the work till next year. In other cases it leads to construction by day labor. Whichever of these two courses is adopted there will be regret. Wages are rising and prices of materials show no sign of falling. Hence, contract prices are apt to be higher next year than now.

Work done by day labor is rarely done as cheaply as by contract. Usually, day labor work on roads costs fully 25% more than if done by contract; and not infrequently the cost is double. Men working for a city, county or state simply will not exert themselves as when working for an individual. The editor travels extensively, and wherever he on a day labor job. It is sophistical reasoning, but you can from a "contract gang" at sight. The typical "contract gang" shows far more energy than the typical "day labor gang."

It is frequently said that "day labor work" would always be as efficient as contract work if good managers were in charge, but this is not true. Whoever has been superintendent or foreman over construction forces, both day labor and contract gangs, knows that it is usually impracticable to get a day labor gang to work as vigorously as a contract gang.

"The State is rich. Don't break your back saving a few cents for the State." "Who put the governor in his soft job? Your votes and mine. Well, the governor appointed the commission; the commission appointed the engineers, and they appointed the foremen. So every last Jack of them owes his job to our votes. Why should we sweat more than the men who owe their jobs to us?" Such is the reasoning of the man that wields the shovel or runs the engine on a day labor job. It is sophistical reasoning, but you can no more convince him of his error than you can persuade a Hindoo that the system of caste is grossly uneconomic.

*From "Engineering and Contracting," Chicago.

ELECTRICITY AND CIVILIZATION

IN connection with the value of water powers, the "Electrical World," of New York, commenting on remarks by Dr. George Otis Smith, Director of the United States Geological Survey, states that, in the long run, the utilization of water power means the saving of human energy for purposes to which power-driven machinery is not yet adapted. The mere change from steam power to water power is not only significant of lower costs in manufacturing and of the saving of the earth's stored fuel for its more important uses, but it relieves the labor necessary in mining the coal and the still greater burden of transporting it.

Every water power harnessed and displacing steam power implies, therefore, a great band of laborers in the mine and on the railways freed from this particular necessity of toil, for other and more useful work. Now that the price of labor has risen beyond the wildest dreams of a few years ago, we are approaching an era when, wherever possible, human energy will be replaced by mechanical or electrical power.

If we are to attain a condition of production that will give us a chance of successful competition in the world's market, it must be through the most determined efforts at cheap power production and all possible saving in the field of human labor. The great power enterprises of the present day give opportunities such as have not yet been realized.—By Leo G. Denis, writing in "Conservation," published by the Commission of Conservation, Ottawa.

ADVISORY BOARD TO DOMINION HIGHWAYS BRANCH CONFERS WITH PROVINCIAL OFFICIALS

OFFICIALS from various provinces met the Advisory Board of the Highways Branch, Department of Railways and Canals, last week at Ottawa, and discussed how the $20,000,000 federal aid should be spent.

Copies of the form to be used in applying for aid, which had been prepared by A. W. Campbell, the head of the Highways Branch, were submitted to and approved by the provincial representatives, and other regulations were also discussed.

Those present from the various provinces were: Nova Scotia, Hon. H. H. Wickwire and Chief Engineer J. W. Roland; New Brunswick, Chief Engineer B. M. Hill; Ontario, W. A. McLean, Deputy Minister of Highways; Quebec, B. Michaud, Deputy Minister, and G. Henry, Chief Engineer; Manitoba, Alex. McGillivray, Chief of the Good Roads Branch; Saskatchewan, Hon. S. J. Latta, Minister of Roads, and his deputy, H. S. Carpenter; British Columbia, A. E. Forman, Chief Engineer, Public Works Department.

The advisory board, of which Hon. J. D. Reid, Minister of Railways and Canals, is chairman, is composed of C. A. Magrath, Ottawa; J. P. Mullarkey, Montreal; and R. Home Smith, Toronto.

RESULTS OF TESTS OF WIRE ROPE

IN "Technologic Paper No. 121," published by the U. S. Bureau of Standards, J. H. Griffith and J. G. Bragg present the results of tests on 275 wire ropes submitted by United States manufacturers to fulfill the specifications framed by the Isthmian Canal Commission in 1912. The samples were selected by government inspectors for acceptance tests of material to be used at the Canal Zone. The following review of the paper appears in "Mechanical Engineering," of New York:—

The ropes ranged in diameter from ¼ to 1½ in., a few being of larger diameters up to 3¼ in. Over half the specimens were plow and crucible cast-steel hoisting rope of 6 and 8 strands, 19 wires each. The remainder were galvanized steel guy rope and iron tiller ropes of 6 strands 7 wires, and 6 strands 42 wires, respectively.

The investigation was made primarily to determine the tensile strengths of the ropes. Much of the experimentation was of a supplementary character—to determine the general laws of construction of the rope as the basis of the interpretation of their physical behavior under stress. A comparative analysis was made of the chemical constituents of steel, rope fibers and lubricants of plow ropes submitted by different manufacturers.

The wires at the ends of specimens were "frayed out" to form a "broom." These were inserted into molds, into which molten zinc was poured so as to form conical sockets for connection to the testing machines. Most of the tensile tests were made on a 600,000-lbs. Olsen testing machine, the ropes of large diameters being tested on the 1,200,000-lbs. Emery machine. Stress-strain measurements were made on over half the specimens. Numerous tests of individual wires were conducted in tensile, bending and torsion machines. The strengths of the cables were studied in connection with their modes of construction, the strengths of their component wires and the types of fractures which were presented.

The homologous linear dimensions of the strands, wires and fiber cores were found to vary in direct proportion to the diameters of the ropes. The diameters of the strands and fiber cores were generally ⅓ the diameter of the rope. The mean pitch or lay of the strands was 7½ diameters. The mean lay of the wire was 2¾ diameters. The mean diameter of the wires was expressed by the equation:—

$$d = KD/(N+3)$$

where d = diameter of wires
D = diameter of rope

N = number of wires in outer ring of wires of a strand

K = { 1.0 for hoisting and guy rope; 0.8 for extra flexible 8 x 19 hoisting rope; 0.33 for tiller rope.

The aggregate cross-sectional areas of the wires was expressed approximately by the equation:—

$$A = CD^2$$

where C = 0.41 for 6 x 19 plow steel hoisting rope
= 0.38 for 6 x 19 crucible steel hoisting rope
= 0.38 for 6 x 7 guy rope
= 0.35 for 6 x 17 plow-steel rope
= 0.26 for 6 x42 iron tiller rope.

It was found when the maximum loads determined from tensile tests were platted as functions of the diameters of the ropes that the curves bounding the lower frontiers of each zone comprising the observed values were in close agreement with similar curves platted from the minimum strength stipulated in the specifications of the Isthmian Canal Commission of 1912. These strengths were also in approximate agreement with the standard strengths recommended in 1910 by the manufacturers from the results of their tests of cables similarly classified. The minimum strengths found from the present investigation are given by the following empirical equation:—

$$\text{Load} = C \times 75{,}000 D^2$$

where D = diameter of wire rope in inches

C = { 0.9 to 1.1 (mean about 1.0) for 6 x 19 plow-steel cables; 0.8 to 0.95 (mean, about 0.9) for 8 x 10 plow-steel and 6 x 19 crucible cast-steel cables. 0.3 to 0.4 (mean, about 0.35) for iron tiller and steel guy rope

The modulus of the rope calculated from stress-strain measurement was found to vary from 3,000,000 to 9,000,000 lbs. per sq. in., depending upon the diameter and class of cable.

Plow-steel ropes were selected for comparative analyses of the constituent materials. In the chemical analyses the carbon content ranged from 64 to 96 per cent., with a mean of about 75 per cent. The manganese ranged from 25 to 68 per cent., the silicon from 11 to 24 per cent. The percentage of phosphorus and sulphur was relatively low. In certain cases the steel of the filler wires was softer than the main wires.

The fibers used in making the core of the rope were estimated as manila, jute, istle, mauritius, manila fiber alone being employed by certain manufacturers. The preservative and lubricants on the cores were composed of wood and vegetable tars, petroleum products, and fish oil, the practice varying somewhat.

There was a reasonable uniformity in the strengths and elongations of the wires from a particular cable, but a larger variation in the strengths of the wires from cables of different manufacturers. This was probably due to the fact that different grades of plow steel were used by the several manufacturers in meeting the provisions of the specifications.

The cables developed from 72 to 90 per cent. of the aggregate strengths of the wires. The upper limit of the ratio of the strength of a rope to the strengths of its wires was found from theoretical considerations to be 89.2 per cent. for 6 x 19 plow-steel cables. The differences between the results of the theoretical analysis and the practical tests were largely attributed to different strengths and degrees of ductility of the wires, this causing an unequal distribution of the load among the strands, with over-stressing of certain strands near the point of failure.

The Civil Service Commission of Canada will receive applications not later than September 6th for the following positions at the Royal Military College, Kingston, Ont.: Professor of engineering, salary $3,480; instructor in physics, $1,800; instructor in civil engineering, $1,800. W. Foran, Ottawa, is the secretary of the commission.

TOWN PLANNING IN EASTERN CANADA*

THE Nova Scotia Town Planning Act has been amended in accordance with suggestions made by the Town Planning Branch of the Commission of Conservation. The Act formerly required that town planning schemes or by-laws had to be prepared before 1918, but the war prevented this being done. Under the amendments made the period for compulsory preparation is extended to 1921. The Act has also been widened in scope to deal with rural as with urban development. The model town planning by-laws of the province have been prepared for recommendation to the municipalities.

Nova Scotia has also passed a Housing Act to enable the province to take advantage of the federal loan. A draft housing scheme is under consideration. In the investigations made into the housing shortage in Canada and the costs of building, it has been found that conditions are worse in Halifax than in any other part of the Dominion, owing to the combined effects of exceptional prosperity and the destruction caused by the disaster of 1917.

The Halifax city and county schemes, covering large areas, are well advanced in preparation.

New Brunswick

The St. John Town Planning Scheme, dealing with over 20,000 acres, has been approved by the councils of the city and the county municipalities. This is an important achievement having regard to the novelty of many of the provisions of the scheme and the somewhat drastic changes which they introduced in local procedure. The scheme has been prepared by the City Planning Commission in consultation with the Town Planning Branch of the Commission of Conservation. The Housing Act of New Brunswick is now on the statute books and a housing scheme has been prepared by the province and approved by the federal government.

Quebec

In Quebec a Housing Act has been passed, a provincial housing scheme has been prepared and a director of housing has been appointed. The Quebec scheme conforms more strictly to the federal scheme than the schemes in any other provinces. Practically all the recommendations of the federal government have been introduced into the Quebec scheme in a mandatory form. The appointment of Dr. Nadeau as director of housing is significant of the importance which the province attaches to the promotion of housing schemes in the form of garden suburbs and with proper town planning provisions. For many years Dr. Nadeau has been an active worker for town planning and housing reform in Quebec.

Although Quebec is the only eastern province without a Town Planning Act, it has introduced town planning provisions in its housing scheme and the intention is to pass a Town Planning Act at the next session of the legislature.

Ontario

The fact that Ontario was responsible for initiating the movement for government housing in Canada and that the province has appropriated $2,000,000 of its own money to be spent in housing, has given it a start in advance of the other provinces in the matter of carrying out housing schemes. The Housing Act and scheme of the province was approved by the Federal government on February 20th last.

J. A. Ellis, an ex-mayor of Ottawa and a member of the Ontario Railway and Municipal Board, has been appointed director of housing, and is giving able leadership to the movement in the province. The director reports that 47 municipalities have already appointed housing commissions and applied for loans, and that the whole of the $10,000,000 available is already spoken for. Actual building operations have begun in Toronto. Two sites of about 40 acres in area have been acquired in the city of Ottawa and are being planned with a view to building operations being started in the immediate future.

PRESSURE RISE IN PENSTOCKS

PRESSURE rise in penstocks, due to gradual gate closure, forms an important problem in hydro-electric developments, as it not only affects the design of penstocks, but also the regulation of the plant, which is of prime importance.

The article which starts on page 269 of this issue opens a new field for the investigation of this problem in regard to its effect upon regulation. Mr. Gibson has applied to slow gate closures Prof. Joukovsky's theory of maximum water-hammer, which had been proven experimentally by Prof. Joukovsky himself in regard to instantaneous gate closures. Mr. Gibson also shows the limitation of several formulas that have been in common use, such as Allievi's, Warren's and Vensano's. The accuracy of these formulas has been a source of contention among hydraulic engineers for several years, due to the assumptions upon which these formulas were based.

The solution presented by Mr. Gibson is entirely general in its application, giving correct results for any time or condition of gate closure. The method of arithmetic integration which he first uses for the solution of the problem, is worthy of special note, as many hydraulic problems that do not lend themselves to analytical solution, can be solved by this method.

Water works engineers will also be interested in this article, as frequently the cause of serious breaks in water mains can be traced to excessive pressure rise due to the sudden shut-down of a pump. It is not likely, however, that the broad application of Mr. Gibson's paper will be universally appreciated at first glance. Indeed, one of the country's leading hydraulic engineers states that it will be fifteen years before its full use is realized to the maximum. This can be readily believed when one considers that Prof. Allievi dealt analytically with this same subject fully 12 years ago in Italy, and that his paper to this day has never been translated into English in its entirety. It may be mentioned that those who are familiar with the original text of Prof. Allievi's work, state that his results coincide with those that have been secured by Mr. Gibson by an entirely different method.

AEROPLANES IN BUSINESS LIFE

PRESENT standards of business efficiency are rapidly undergoing readjustment on account of the introduction of the aeroplane to everyday business activities.

Previously, when an engineer requested samples, he thought that the firms with whom he was dealing were very prompt and efficient if his letters were answered by return post and samples mailed at once by parcels post or express. To-day, the samples are likely to arrive by aeroplane.

A few years ago, when an engineer offered plant for sale, machinery firms sent representatives by train to inspect it, and if they arrived within several days after their presence had been requested, their firms were said to be "right on their job." The modern machinery man is likely to land at your factory door in an aeroplane within a few hours after he gets your letter or telegram.

This will certainly influence the rapidity with which business will be transacted in the future. The example set by a few enterprising firms will extend, and soon hundreds of business men will learn aviation or employ aviators in order to prevent their more venturesome rivals from stealing a march in important deals. Or should we say, stealing a flight?

One alert young business man in Toronto, A. R. Roberts, a dealer in contractors' equipment, declares that he intends to use an aeroplane for business trips to all parts of Ontario, whenever the weather is suitable and the business urgent. A fortnight ago he flew from Toronto to Owen Sound to inspect a boiler in order to be able to effect its immediate purchase for a client. He left Toronto at 2 p.m., stayed in Owen Sound for 2½ hours, and was home in time for dinner at 7 p.m. The scheduled time for trains from Toronto to Owen Sound (one way) is more than five hours. Mr. Roberts began the study of aviation only a couple months ago and purely for business purposes. If he finds it worth while to go to that trouble, are not scores of returned officers, who have had extensive experience in flying at the front, likely to find that their knowledge of aviation is a real asset in peaceful pursuits?

In the United States a large manufacturer of contractors' equipment is now using an aeroplane for advertising purposes. Lt. George M. Comey, late of the A.E.F. air service, and a Curtiss biplane are engaged in distributing free copies of the "Lakewood Aerial Bulletin," a clever house organ published by the Lakewood Engineering Co., of Cleveland. The first issue contains numerous illustrations of Lakewood equipment and also a number of witty remarks, including the following:—

"These bulletins are dropped in an attempt to reach a height equal to that of the quality of the Lakewood line.

"Circulation, highest in the world. No copies delivered by mail or newsboys.

"After decreasing the weight of his plane by dropping these bulletins, Lt. Comey was still unable to reach an elevation equal to the Lakewood standard.

"Frank A. Michell, general purchasing agent of the Lakewood Engineering Co., is accompanying Lt. Comey on this trip. Mr. Michell does not intend to place any orders on the way, but, as he says, just to find out if he can see the top of the high prices."

In the last issue of "Engineering News-Record," of New York, there appeared the following interesting editorial on aeroplane passenger traffic:—

"Speculation has naturally been rife among laymen as to the probability of the early introduction of the aeroplane into regular passenger service. Its possibilities appear to be so great that one is eager to see the predicted development

begin. For some time there has been regular passenger service between Paris and Brussels, while this week's cables tell of the inauguration of service between London and Paris. Those who have studied the situation account for the slowness of development on two grounds—the natural conservatism of capital in venturing into a new and untried field beset, apparently, by peculiar hazards, and the lack of suitable, centrally located landing fields. They do not believe that the dangers of aeroplane travel, when calmly considered, are a deterrent from the standpoint of the operating company, though the risks may tend to discourage prospective passengers. Aeroplane travel, of course, is not attended with the degree of safety of rail or even water travel, but the constant use of aeroplanes for transporting British diplomats between London and Paris, from the very beginning of the peace conference, shows the confidence of the British air service and British officials in this mode of travel. Safety measures are receiving careful study—parachute experiments, for example—and these will go far to remove the fears that the public now entertains. As to landing fields, a new civic and civil engineering problem enters here. The landing of passengers far out in the suburbs is naturally a handicap, even though automobiles are in waiting. In this respect, too, advances are to be looked for. Landing and starting in smaller areas than are now felt necessary will surely come. Incidentally, the success of the New York-Washington aeroplane mail service should not be forgotten. It gives warrant for the optimism of those who contend that there is no physical reason why a New York-Chicago passenger aeroplane service should not be in operation."

PERSONALS

CAPT. BRUCE ALDRICH, who has been appointed as the Asphalt Association's district engineer for Canada, was born in London, Eng. He was brought to Canada at an early age and received his primary education in the public schools of Ottawa, returning later to England for further study. Again leaving England, Capt. Aldrich went to the United States and served as a volunteer in the United States army in the Spanish-American and Phillipine wars. In 1901, he joined the staff of the inspector of asphalts and cements, engineer department, District of Columbia, where he served until February, 1912, in various capacities, testing paving materials under Prof. A. W. Dow, of New York City. In March, 1912, he went to Baltimore, Md., which was then undertaking the biggest paving program in the history of that city, with expenditures aggregating nearly $15,000,000. Capt. Aldrich organized and equipped the municipal laboratory, in which were tested all the materials entering into the new paving. As inspector of asphalts he supervised the laying of more than 3,000,000 sq. yds. of sheet asphalt and bituminous concrete, having at times as many as seven asphalt plants working simultaneously. He assisted also in the inspection and construction of all vitrified brick and concrete block pavements laid in Baltimore. When the United States declared war upon Germany, Capt. Aldrich volunteered in an infantry battalion and served at the front for one year with the rank of captain. He returned to the United States last June and resumed his Baltimore position, which he has now resigned in order to accept the appointment with the Asphalt Association. The head office of the Asphalt Association is at 15 Maiden Lane, New York City. With the staff at that office, Capt. Aldrich will be in close touch, but his personal headquarters will be in Toronto. On account of the present crowded condition of office space in Toronto, he will make his headquarters at the office of the H. K. McCann Co., 56 Church St., until he can find suitable offices. It is his intention to co-operate gratuitously in every way possible with municipal officials, consulting engineers and others in obtaining the best results in the construction of asphaltic pavements of all types. His work will be impartially in the interests of all asphalt producers and his services will be equally available whatever kind or brand of asphalt may be used in the construction.

C. A. LOUNT, superintendent of water works at Cornwall, Ont., has placed his resignation in the hands of the town council.

IVAN WALKER has been appointed chief engineer of the Kitchener Water Commission to succeed his father, who has resigned.

WILLIS CHIPMAN, who designed the William Head Quarantine Station's water works system, at Victoria, B.C., recently visited that city for the purpose of testing the plant.

J. I. NEWELL, electrical superintendent, British Columbia Electric Railway, Vancouver, B.C., has taken over the hydro-electric engineer's duties, succeeding F. S. Easton, who resigned to join the Mexican Light & Power Co.

MAJOR CECIL EWART, formerly of the 8th Battalion, Canadian Railway Troops, is now engaged in locating a line from the Pacific Great Eastern Railway at Clinton, B.C., to Ashcroft, B.C., for the Department of Railways of British Columbia, of which department F. C. Gamble is chief engineer.

GEO. H. BRYSON, city engineer of Brockville, Ont., intends to resign in order to become manager of the Brockville Highway Construction Co. Mr. Bryson is financially interested in this company, which has just secured a large contract for penetration bituminous road construction for the province of Ontario.

CAPT. LUCIUS A. FRITZE has become associated with the technical staff of Wallace & Tiernan Co., Inc., of New York City, manufacturers of chlorine control apparatus. Capt. Fritze, who was sanitary officer of the Rainbow Division, U.S. Army, after the armistice, was assigned to the office of the Surgeon-General in Washington, and while there prepared a history of the Sanitary Corps of the A.E.F. Capt. Fritze will be the manager of a new office which Wallace & Tiernan Co. are opening at Kansas City, Mo.

OBITUARY

THEODORE COOPER, one of the continent's leading bridge engineers, died August 24th, in New York City, at the age of 80 years. He began private practice in 1879. His name became universally familiar through his system of locomotive and train loadings for bridge design. Composed of a wheel system representing the heaviest locomotives of that time, followed by a uniform load whose amount in pounds per foot bore a simple relation to the driving-axle load, this system proved so convenient, and was so excellently adapted to modification for increasing weight of trains and engines by simple multiplication, that it quickly won a commanding position, and for many years has been the almost universal standard for railway-bridge design. Mr. Cooper was born at Cooper Plains, N.Y., and was a graduate of Rensselaer Polytechnic Institute.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

BRIDGES, ROADS AND STREETS

Annapolis Royal, N.S.—Contract has been awarded by the board of highway commissioners, department of public works, Halifax, for concrete abutments and bridge sheets on ten existing piers to the Engineers and Contractors, St. John, N.B. J. W. Roland, chief engineer.

Aurora, Ont.—Town council will pave Yonge St. within the town limits this year.

Brockville, Ont.—Town council contemplates construction of pavement on Pine St., from Wall to Park St. Estimated cost, $12,094.

Brome, Que.—Contract has been awarded to the Phœnix Bridge Co., Montreal, for construction of steel bridge. Cost, $12,000.

Chilliwack, B.C.—City council has recommended to the public highway department, Victoria, that the tender of the Columbia Bitulithic Co., Ltd., for surfacing the Yale macadam roadway within the city limits be accepted.

Comber, Ont.—Council proposes to construct a reinforced concrete roadway and drain on Queen St. J. J. Newman, engineer, Davis block, Windsor.

Edmonton, Alta.—City council proposes construction of a cinder walk on west side of 123rd St., between 113th and 114th Ave. C. E. K. Cox, city clerk.

Fredericton, N.B.—Surveys are being prepared for the purpose of changing the location of the highway bridge over the Nerepis stream in Petersville, Queen's County. P. J. Veniot, minister of public works.

Galt, Ont.—City council proposes to construct an asphaltic concrete pavement and concrete curbs and gutter on Wellington St., from Main St. to north side of Dickson St. Estimated cost, $5,902.30. Joseph McCartney, city clerk.

Markham, Ont.—Contract has been awarded by township council for construction of three concrete bridges to R. H. H. Blackwell, Aurora. James, Loudon and Hertzberg, Toronto, engineers.

Matilda Township, Ont.—Tenders will be received until 7 p.m., September 12th, for construction of two concrete culverts, 10 ft. span, road No. 2, concessions Nos. 1 and 4. J. G. Cameron, county road superintendent, Finch.

Nanaimo, B.C.—Ratepayers of Haliburton St., will request council to construct permanent pavement.

Newmarket, Ont.—Town council contemplates constructing permanent pavements on Yonge St.

Ottawa, Ont.—Contract has been awarded by C.N. Ry. for construction of concrete culverts, bridge abutments and piers between mile 59, L'Orignal and Ottawa on the Grenville subdivision to C. L. Hervey, Williamstown, Ont. A. F. Stewart, chief engineer, Toronto.

Ottawa, Ont.—City council proposes to construct asphalt pavements on Queen St., Bay St. to Bronson Ave. Estimated cost, $10,811.46. Besserer St., Charlotte St. to east limits of lot No. 58. Estimated cost, $10,952.26. N. H. H. Lett, city clerk.

Ottawa, Ont.—The Chaudiere bridge is being moved to temporary piers to permit of construction of new steel and reinforced concrete bridge. Estimated cost of bridge, $110,000. Contractor, Dominion Bridge Co. Chief engineer, public works department, R. De B. Corriveau.

Owen Sound, Ont.—The Warren Bituminous Co. will start construction on their contract for 30,000 sq. yds. of bituminous pavement within a couple of weeks, just as soon as the portion of their plant that is now in use at Orillia is released by the completion of the Orillia contract.

Owen Sound, Ont.—Town council proposes to construct concrete curbs on 2nd Ave. East, from 6th St. to Jubilee Bridge and on 12th St. West, from 4th Ave. West to 6th Ave. West. D. H. Fleming, town engineer.

Pembroke, Ont.—Council contemplates construction of improved roadways on the following streets: Sussex St., from McKay to Commercial St.; McAllister St., from McKay to Commercial St.; Pembroge St., from Commercial to Arnold's Lane and from Hincks St. to Moffat's crossing; Isabella St., from Maiden Lane to Doran St., and the widening and production of Lake St., together with a bridge over the Muskrat River. W. J. Moore, town engineer.

Portage la Prairie, Man.—Contract has been awarded to H. E. Walker Co. for construction of 12 miles of roadway between Portage la Prairie and Winnipeg. Contract price, $25,200.

TOWNSHIP OF YORK

Sealed tenders, plainly marked as to contents will be received by the undersigned for the Municipal Corporation of the Township of York, up to 12 o'clock **Noon** of **Saturday, September 13th.** for the construction of the following works:—

Tarvia X Pavements on Glenholme Ave. and Pinewood Road.

Concrete sidewalks on Atlas Ave., Glenholme Ave., St. Clair Ave., St. Johns Road, Miller Ave., Frejama Ave. and Dennis Ave.

Plans and specifications and all necessary information may be obtained at the office of the engineer, Frank Barber, 40 Jarvis Street, Toronto.

The lowest or any tender will not necessarily be accepted.

FRANK BARBER,
Engineer.

Toronto, Sept. 2nd, 1919. 345

Prince George, B.C.—The provincial government is having surveys prepared for the construction of a permanent roadway and bridge over the Fraser River into the Mount Robson country. Construction of the bridge will start immediately. Hon. Dr. J. H. King, minister of public works. H. Taylor, bridge engineer.

Regina, Sask.—City council will submit by-law to the ratepayers, September 11th, providing for permanent paving on spur track crossings in warehouse district. Estimated cost, $14,000.

Reston, Man.—The municipality of Pipestone will construct a 25 ft. standard girder bridge over Gopher creek, east of section 36-9-27. G. F. Birney, secretary-treasurer, Reston, Man.

South Mountain, Ont.—Tenders will be received until 7 p.m., September 12th, for construction of one-half mile of macadam on road No. 1. Yardage of crushed stone, 2,000. J. G. Cameron, county road superintendent, Finch.

St. Adelaide de Pabos, Que.—Contract has been awarded by the department of public works, Quebec, for construction of a steel bridge to the Mackinnon Steel Co., Ltd., Sherbrooke, Que.

St. Hyacinthe, Que.—Contract has been awarded by the department of public works, Quebec, for construction of bridge to J. Herbert. Contract price, $20,000.

St. John, N.B.—The department of works is preparing to pave Union, Germain and Brussels Streets. G. N. Hatfield, city engineer.

Toronto, Ont.—Contracts have been awarded by the highway department of the department of public works, Ontario, for construction of provincial highway as follows: Section No. 1, easterly limit of city of London to westerly limit of town of Ingersoll, 15.93 mls., to Frid Construction Co., Toronto; section No. 2, easterly limit city of Brantford to village of Ancaster, 15.62 mls., to D. O. Johnston, Brantford; section No. 3, from easterly limit of the village of Beamsville easterly 3.25 mls., no tender; section No. 4, easterly limit, town of Trenton, to westerly limit, city of Belleville, 9.13 mls., not yet awarded; section No. 5, westerly limit, city of Kingston, to westerly limit, township of Kingston, 7.72 mls., J. G. Murphy, 28 Dominion St., Toronto; section No. 6, easterly limit, city of Brockville, to westerly limit town of Prescott, 10.46 mls., to Brockville Construction Co. W. A. McLean, deputy minister.

Toronto, Ont.—The Toronto Harbor Commissioners will start construction of boulevard, from the Humber river, 8,000 lin. ft. easterly. This work will be done for the city of Toronto and constitutes part of the 12 mls. of boulevards designed for the water front.

Victoria, B.C.—The department of public works will soon commence construction of pavement on Lulu Island, road No. 3, and the Revelstoke west road.

Victoria, B.C.—The abutments are being constructed, and the new steel bridge over Deep creek, 20 mls. s. of Williams lake, on the P.G.E. Ry., will shortly be erected. Contractor, Northern Construction Co.

Windsor, Ont.—Council proposes to pave London St., from Ouellette Ave. to Windsor Ave. Estimated cost, $19,-190. M. E. Brian, city engineer.

WATER, SEWAGE AND REFUSE

Andover, N.B.—Contract has been awarded by the council for construction of concrete arch culvert and roadway embankment to J. E. Armstrong, Perth. Contract price, $2,800.

Aurora, Ont.—Town council will construct sewers on Yonge St., preparatory to constructing pavements.

Carleton Place, Ont.—Town council has been requested by the public utility commission to provide $11,600 for water-main and sewerage construction. W. Baird, chairman of commission.

Chatham, Ont.—City council will construct sewers on Forest St., Bedford St. to Van Allen Ave., and on Bedford St., Forest St. northerly.

Cobourg, Ont.—Town council has decided to construct drains on King St. W., from McIntosh's corner to the factory creek. Estimated cost, $2,000. Reeve Semple.

Edmonton, Alta.—City council will construct sewers along the following lanes: West of 80th St., from 122nd Ave. to Advie Ave.; west of 81st St., from 122nd Ave. to Advie Ave.; west of 90th St., from 120th Ave. to 122nd Ave.; west of 127th St., from C.N. Ry. to 108th Ave.; west of 127th St., from 109A Ave. to 114th Ave.; west of 129th St., from 111th Ave. to 112th Ave. C. E. K. Cox, city clerk.

Ford City, Ont.—Town council will construct vitrified pipe sewers on Pellette Rd., from Ottawa St. to the G.T. Ry., on Lawrence St., from Ottawa St. to the s. side of lots No. 80 and 160, on Dawson Rd., from Ottawa St. to the s. side of lots 196 and 273, and on Ottawa St., from Dawson Rd. to Pellette Rd.

Galt, Ont.—City council proposes to construct the following sewers and storm drains: Borden St., First Ave. to Stanley St.; Stanley St., Borden St. to Tait St.; and on Tait St., Stanley St. to Francis St. Estimated cost, $3,006.89. Simcoe St., King St. to bend in Simcoe St. Estimated cost, $375. Joseph McCartney, city clerk.

Newmarket, Ont.—Contract has been awarded by the town council to McNamara Co., Sault Ste. Marie, for construction of sewers on Eagle St., Water St. and Main St. P. J. Anderson, clerk.

Owen Sound, Ont.—Contract has been awarded to John Cross by town council for construction of sewers on 10th St. W. at $1.25 per ft. and on 2nd Ave. W. at $1.35 per ft. D. H. Fleming, engineer.

Pembroke, Ont.—Town council contemplates construction of six-inch water mains on McAllister St., from McKay to Commercial St., cost $1,320; and on Isabella St., from Maiden Lane to Doran St., cost $4,510. W. J. Moore, town engineer.

Pembroke, Ont.—Plans have been prepared for construction of drains on Government Rd., Christie St., Forced Rd. and Bell St. Plans will also be prepared for construction of storm sewers on Somerset, Cecelia and Fraser St. W. J. Moore, engineer.

Port Arthur, Ont.—Board of works recommended to council construction of sewer and water connections on Shortiss St.

Regina, Sask.—City council will submit by-law to ratepayers on September 11th, providing for sewer and water connections. Estimated cost, $7,000.

Sandwich, Ont.—Town council will construct vitrified crock sewers on Indian Rd., London to Peter St., and on Peter St., Indian Rd. west to Pajot Lane. E. R. North, clerk.

St. Thomas, Ont.—C. W. Tarr, of the firm of Morris and Knowles, Ltd., Windsor, is making preliminary surveys to locate suitable place for waterworks storage dam.

Welland, Ont.—City council will construct sewers on River Rd., Gadsby Ave., Margaret St. and Cohoe St. C. L. Coulson, city engineer.

Windsor, Ont.—The ratepayers of Windsor will vote on the scheme for joint water system for seven border municipalities, next January.

Winnipeg, Man.—City engineer estimates that asphalt paving on Logan Ave, from East St. to McPhillips, will cost $128,948. Construction will probably commence next spring. W. P. Brereton, city engineer.

Winnipeg, Man.—Contract has been awarded by the department of public works, Winnipeg, for excavating 300,-000 cu. yds. material in drainage district No. 2 to Carter, Halls and Aldinger, Winnipeg. Contract price, 22.5 cents per cu. yd. G. A. Grierson, minister.

Winnipeg, Man.—Estimates are being prepared for the board of the Greater Winnipeg Water District for under-

20-Year Barrett Specification Roof on Foundry Bldg. of Thos. Davidson Mfg. Co., Ltd., Montreal, Can. Arch.: A. W. Robinson, Montreal; Gen. Con.: A. F. Byers & Co., Montreal; Roofers: Hickey & Aubut, Montreal.

A 20-Year Guaranty Roof protects this Canadian Foundry—

A foundry roof has more than weather to withstand. It must be able to resist the intense heat of the furnaces underneath, and showers of red-hot sparks from above.

When the roof on the foundry building shown above was completed we gave the owners a Surety Bond *guaranteeing* their roof to be free from maintenance expense for *20-years.*

In this case the Surety Bond was hardly necessary, for the Thos. Davidson Mfg. Company, Ltd. knew from experience what service to expect, as the following paragraph from their letter to us shows:

"You will no doubt be interested to know we have insisted on Barrett Specification Roofs on all our plants, as our experience has proved it to be in every way satisfactory."

Not only are Barrett Specification Roofs "in every way satisfactory," but they cost less per-year-of-service than any other type of permanent roof, and they take the base rate of fire insurance.

20-Year Guaranty

So sure are we of the service Barrett Specification Roofs will give *under the most severe conditions,* that we are prepared to *guarantee them for 20 years,* in all towns of 25,000 or over, and in smaller places where our Inspection Service is available provided they are 50 squares or more in area. The guaranty costs you nothing. We merely require that our Specification dated May 1, 1916, shall be strictly followed and that we have an opportunity to send inspectors to watch the job during construction. The guaranty is a Surety Bond issued by a well-known fidelity and guaranty company.

Copies of The Barrett Specification, with roofing diagrams, mailed free on requesst

The Barrett Company LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER
ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

drainage of portions of the aqueduct line from Winnipeg through St. Boniface to six miles beyond Deacon. W. G. Chase, chief engineer.

Winnipeg, Man.—The city council will construct the following water mains: Dominion St., from Notre Dame Ave. to s. line, lot No. 25; Minto St., from s. line, lot No. 40, block No. 3; Dundas St., from Sargent Ave. to 449 ft. s. of Alberta St. C. J. Brown, city clerk.

York Township, Ont.—Tenders will be received until 12 o'clock noon, September 13th, by the municipal council, for construction of 6 in. cast-iron water mains in the following streets: Pinewood Rd., Atlas Ave., about 2,030 ft.; Morningside Ave., Kingsway, Garboyd Pl., Garboyd Ave., Riverside Dr., Mossom Rd., about 5,500 ft. Engineer, Frank Barber, 40 Jarvis St.

York Township, Ont.—Township engineer has surveyed and is preparing plans for a drainage system for the eastern section of the township. It is proposed to construct sewers which will discharge from a purification plant into the Don River. Five sites have been examined. The one which has been recommended by the engineer is land west of Don River in line with Westwood Ave. and adjoining the Don Valley Brick Works. Area, 11.38 acres. R. O. Wynne-Roberts, 40 Jarvis St., Toronto.

LIGHT, HEAT AND POWER

Carleton Place, Ont.—The public utilities commission contemplate the purchase of the Burgess electric system, repairs and enlargements. Wm. Baird, chairman. Estimated cost, $12,000.

Goderich, Ont.—The Lake Huron Steel Corporation plan to use 22,000 horse-power when fully operating; 15,000 horse-power will be used by next year.

Lethbridge, Alta.—The Federal Mines are considering construction of a power line to their plant across the river from the city power house.

Regina, Sask.—City council will submit by-law to the ratepayers on September 11th, providing for extension of light and power distribution systems. Estimated cost, $40,000.

Stratford, Ont.—The new Hydro-Electric Power distributing plant and the city waterworks were formally opened last Friday.

Swift Current, Sask.—A new auxiliary gas-producing power unit is being installed in the power house.

Winnipeg, Man.—The department of Indian Affairs will install an electric lighting plant in the Fort Alexander Indian boarding school. J. R. Bunn, inspector, Chambers of Commerce, Winnipeg.

RAILWAYS

Bridgeburg, Ont.—Hydro-Electric engineers have commenced surveying right-of-way for hydro-radial line, from Port Colborne to Bridgeburg.

Glace Bay, N.S.—It is understood that a railway will be constructed from Port aux Basques to Curling, Nfld., distance, 130 miles.

Scarboro, Ont.—The amalgamated ratepayers will meet September 5th to discuss construction of hydro-radials. R. Tucker, president.

St. George, Ont.—A deputation from St. George will request the Hydro-Electric Power Commission to construct the proposed Hamilton-Galt radial through the village. D. Jackson, St. George.

Swift Current, Sask.—The C.P. Ry. has commenced construction of a branch line, from Wymark to Archive, Sask.

Welland, Ont.—The N.W. and L. E. Street Ry. Co., contemplates construction of extensions into the north ward. A. J. J. Brennan, mayor. Harry Schofield, president, N.W. and L.E. Ry.

FACTORIES AND LARGE BUILDINGS

Ashburnham, Ont.—Town council will prepare plans for a fire hall to be located in east city. Mayor Duncan.

Brantford, Ont.—Robbins and Meyers Co., Springfield, Ohio, will erect a new factory for small motors and electric fans.

Brantford, Ont.—The Brantford Computing Scale Co. has received a permit for construction of additions to plant. Estimated cost, $11,000.

Brantford, Ont.—Contract has been awarded to Secord and Sons' Construction Co., Ltd., by the Slingsby Co. for construction of additional buildings to their plant. Estimated cost, $200,000.

Calgary, Alta.—A new Allen theatre will probably be constructed on Eighth Ave. Estimated cost, $200,000.

Calgary, Alta.—Contract has been awarded by the Western Canada College for construction of new building to Bennett and White Co. Contract price, $5,500.

Calgary, Alta.—The Studebaker Co. has plans prepared for duplicating its plant in South Bend. It is understood that construction will proceed as soon as housing accommodations have been secured. Estimated cost of extensions, $8,000,000. The erection of 4,000 homes for an additional 12,000 employees is contemplated. Estimated cost, $9,000,000. A. R. Erskine, president.

Capreol, Ont.—The C.N. Ry. will construct a railroad Y.M.C.A. immediately. Estimated cost, $75,000.

Capreol, Ont.—Town council will submit by-law to the ratepayers, September 20th, providing for construction of fire hall and purchase of fire engine, apparatus and appurtenances for fire protection. W. H. Mathews, clerk. Estimated cost, $8,000.

Capreol, Ont.—Construction work to be undertaken this summer includes the following: Northern Investment Co., 14 houses, cost $42,000; C.N. Ry., 16 houses, cost $48,000; Rossman's theatre, cost $20,000; R.C. church, cost $40,000; and a Masonic temple, cost $22,000.

Dalroy, Alta.—Tenders will be received until noon, September 6th, by board of trustees, Turner school district No. 3,797, for construction of frame school building. F. W. Fraser, secretary-treasurer.

Drummer Township, Ont.—Council contemplates constructing an addition to the town hall as a soldiers' memorial. R. Deen, clerk.

Edenwold, Sask.—Contract has been awarded by school board to Waterman and Waterbury Co., Regina, for construction of school. Contract price, $10,000.

Edmonton, Alta.—R. A. Barrow has awarded contract for construction of garage on 103rd St. to Frost and Ingram. Estimated cost, $11,500.

Essex, Ont.—Dr. Doyle has awarded contract to W. N. McEachren and Sons, Ltd., Toronto, for construction of ten modern houses on Talbot St.

Ford, Ont.—Tenders will be received by the board of education until 5 p.m., September 5th, for construction of a school building on Drouillard Rd. J. C. Pennington, architect.

Fort William, Ont.—F. H. Keefer may convert the convalescent home, which is closing, into an apartment house by the addition of two more stories. Estimated cost, $150,000.

Fredericton, N.B.—The proposed Fraser memorial hospital buildings, planned in connection with the present Victoria public hospital, will be built in the near future. Tenders recently called were considered too high and new tenders will probably be called for immediately. Archibald Fraser.

Goderich, Ont.—The Lake Huron Steel Corporation has secured a 250-acre site along the water front, and will construct a large steel plant. Estimated total cost, $8,000,000. E. R. Wigle, mayor.

Hamilton, Ont.—By-laws will be prepared to provide for construction of Hunter St. school, $120,000, alterations to

Central school, $33,000, installation of a household science department, new memorial school, $35,000.

Indian Head, Sask.—Contract has been awarded by the department of public works, Ottawa, for construction of a brick office building for the forestry branch of the experimental farm, to Wilson and Wilson, Regina. Contract price, $30,000. R. C. Desrochers, secretary.

Ingersoll, Ont.—Council has been requested by the board of education to prepare and submit to the ratepayers a by-law authorizing construction of a new school. Estimated cost, $120,000.

Kitchener, Ont.—The water commissioners will construct and equip a new pump house over the well on Strange St. Capacity of well, 500,000 gallons per day. Superintendent Hymmen.

Kitchener, Ont.—A committee has been formed to obtain funds for construction of a Y.M.C.A. building. F. J. McKellar, secretary.

Leaside, Ont.—Tenders will be received until 6 p.m., September 10th, by the architect, for construction of houses. Plans, etc., at office of Canada Wire and Cable Co., Leaside. Architect, W. L. Somerville, Imperial Bank building, Yonge and Bloor St., Toronto.

London, Ont.—City council contemplates addition to buildings and extensions to fair grounds. A. M. Hunt, secretary, Western Fair Board, London.

London, Ont.—Loew's London Theatre Co. have received permit for construction of new building on Dundas St. Estimated cost, $210,000. Architect, T. W. Lamb, New York. Contractor, P. H. Secord and Sons, Hamilton.

Maidstone, Sask.—Contract has been awarded by the school board for construction of school to Waterman and Waterbury Co., Regina. Contract price, $12,500.

Markinch, Sask.—The school board will erect a new building. Storey and Van Egmond, architects. W. L. Leggett, secretary.

Melfort, Sask.—Tenders will be received until September 5th, by the board of the Melfort public school district No. 1,037, for construction of a four-roomed, brick, steam-heated bungalow school, with full basement. Architect, J. Melrose Morrison, 325 Drinkle block No. 1, Saskatoon.

Montreal, Que.—A committee has been formed in connection with the proposed construction of St. Mary's memorial hospital. M. J. Fennell, Jr.

Montreal, Que.—L. A. Dubrule has purchased the Dow property on Phillip Place and will build a moving picture theatre. Estimated cost, $200,000.

Montreal, Que.—The board of directors of the National Breweries have decided to enlarge their buildings. Estimated expenditure, $500,000.

Moose Jaw, Sask.—The MacLean Grocery and Lloyd's Fruit Co., Ltd., will erect a warehouse at corner of Seventh Ave. and Osler St., immediately. R. C. Bunyard, architect.

Moose Jaw, Sask.—The city council will construct a public comfort station on block No. 93, old No. 96. George D. Mackie, city commissioner.

Mullin's Brook, N.B.—A plant to manufacture hardwood lasts and furniture will be constructed. H. Mobbs, Kettering, England.

Nacmine, Alta.—Contract has been awarded by the school board district No. 3,771, for construction of school to A. P. Johnston, Drumheller. Contract price, $7,790. Rejected tenders, Allison and Gray, Calgary, $7,800; J. B. Parsons, Drumheller, $7,893; A. Buvyer, Drumheller, $8,153. C. Campbell, secretary-treasurer.

Oak Bay, B.C.—A by-law will be submitted to the ratepayers providing for construction of an eight-roomed school. Estimated cost, $94,000, of which the provincial government will grant $30,000.

Oak Ridges, Ont.—The ratepayers' association contemplates construction of a new high school building.

Oshawa, Ont.—The Pedlar People will construct modern factory buildings on Simcoe St. S.

Ottawa, Ont.—Construction of the new government building, Hunter block, Queen St., is rapidly nearing completion. Cost, $1,000,000.

Petitcodiac, N.B.—The Bank of Nova Scotia will construct a new bank building on the site of the old Mansard House.

Port Stanley, Ont.—The L. and P.S. Ry. Commission proposes to erect an amusement and recreation building on the beach, south of the incline railway. Architect Blackwell.

Prince Rupert, B.C.—Council proposes construction of a brick and stone school building on the Acropolis site. Estimated cost, $150,000. Mayor McClymont.

Regina, Sask.—Contract has been awarded by the Saskatchewan Co-operative Creameries Co. for construction of foundations for new brick and reinforced concrete creamery to Poole Construction Co. W. A. Wilson, manager.

Regina, Sask.—The Goodyear Tire Co. have awarded contract to the McKay Construction Co. for erection of a three-story brick and reinforced concrete office and warehouse on Broad and Sixth Ave. Estimated cost, $75,000. W. A. Pope, manager.

Saskatoon, Sask.—Contract has been awarded by the public school board for construction of Mayfair school to A. W. Cassidy and Co., Saskatoon.

Saskatoon, Sask.—By-law will be submitted to the ratepayers, September 4th, providing for construction of school building. Estimated cost, $175,000. R. Blackwood, architect.

Sillery, Que.—A pulp and paper mill may be established at Sillery, by American capital.

Stratford, Ont.—The park board contemplates construction of a pavilion in Queen's Park. City engineer, A. B. Manson.

Toronto, Ont.—The Hydro-Electric Power Commission of Ontario is drilling test holes to locate suitable foundations for additions to the present building on University Ave.

Vancouver, B.C.—A combined public hall and apartment house will be erected on Granville St., near Eighth Ave. Estimated cost, $15,000. T. Edwards.

Vancouver, B.C.—N. Lang has received a permit to construct a factory on Industrial Island for manufacture of electrical fixtures. Estimated cost, $3,000.

Victoria, B.C.—J. R. Thomas contemplates construction of a modern theatre for development of amateur talent. Estimated cost, $200,000.

Windsor, Ont.—A departmental store is being erected on Wyandotte St. for Paul Gilbert. Estimated cost, $30,000.

Windsor, Ont.—A new theatre and seven-story office building will be erected by the J. J. Allen, Toronto, on Ouellette Ave.

Windsor, Ont.—H. Lukos, 13 Pitt St. east, has purchased building from Dr. J. A. Menard, and will construct two additional stories.

Windsor, Ont.—By-laws granting concessions to different companies will be voted upon September 20th. The Fisher Body Co. will erect a plant costing $150,000 if the by-law is carried.

Winnipeg, Man.—The Reliance Ink Co. have decided to construct an addition to their warehouse on McGee St. Estimated cost, $8,000.

Winnipeg, Man.—The city council contemplates construction of a municipal dairy. Estimated cost, $600,000. Charles Gray, mayor.

Winnipeg, Man.—A motion picture theatre will be constructed on the site of the Fort Garry market, between Paris building and Ellice Ave. Theatre to be completed this fall. Estimated cost, $150,000.

Winnipeg, Man.—C. H. Crane and Co. will erect a new theatre on Donald St. for the Allen syndicate. Estimated cost, $205,000.

Winnipeg, Man.—Contracts have been awarded by city council for erection of show room building for city light and

MISCELLANEOUS

Berthier, Que.—Contract has been awarded by the department of public works, Ottawa, for repairs to wharf to Mozaire Le Saurneau, Montmagny. Contract price, $18,500. R. C. Desrochers, secretary.

Calgary, Alta.—The board of trade has adopted a resolution requesting the Dominion government to make such an appropriation, at the coming session of parliament, as will be sufficient to determine the location of canals, reservoir capacity, additonal acreage to become available under irrigation, acreage which can be watered for stock, etc. Areas referred to, lie between the North and South Saskatchewan, the Battle and Red Deer rivers.

Cobourg, Ont.—Town council has decided to purchase a Chevrolet fire truck fitted with two chemical tanks and 200 ft. of hose. Estimated cost, $2,650. Reeve Semple.

Coleville, Sask.—The Rural Telephone Co. will construct additions to its present system. George Manning, secretary.

Dundas, Ont.—Contract has been awarded by the Canada Crushed Stone Corp. for construction of storage bins, steel towers, etc., to F. F. Fry, Toronto.

Edmonton, Alta.—City council will receive a report from the superintendent of the streets department for construction of a new incinerator which will be so arranged as to provide steam heat to the Royal Alexandra hospital. D. Alton, superintendent.

Hamilton, Ont.—Tenders will be received until 12 o'clock noon, September 11th, by the Parks board, city hall, for reconstruction of wharf at Wabasso Park, Hamilton. Specifications and forms of tender may be obtained at office of E. R. Gray, city engineer. A. J. Wright, chairman of Parks board.

Hamilton, Ont.—The Dominion Steel Foundry Co. will open an agency for shipbuilding and railway supplies. C. W. Sherman, president.

London, Ont.—City engineer is preparing a report to council recommending purchase of several tractors to work on construction programmes. H. A. Brazier, city engineer.

Montreal, Que.—Tenders will be received until 12 o'clock noon, September 16th, by the Harbor Commissioners, Montreal, for cribwork construction timber, ship-building timber, British Columbia timber and railway ties. F. W. Cowie, chief engineer. M. P. Fennell, secretary.

North Battleford, Sask.—Tenders will be received until 1 p.m., September 8th, by the department of telephones, for the erection of a fire-proof exchange building. Plans, etc., at office of architects, Storey & Van Egmond, Regina, and at telephone exchange, North Battleford. D. C. McNab, deputy minister, department of telephones, Regina.

Oshawa, Ont.—The ratepayers have carried a by-law to purchase the present factory site of the Pedlar People for park purposes. Purchase price, $50,000.

Petit Rocher, N.B.—New tenders are being called by the department of public works, Ottawa, until 12 o'clock noon, September 16th, for repairs to breakwater at Petit Rocher. Plans, etc., office of district engineer, Chatham, N.B., and post office, Petit Rocher, N.B. R. C. Desrochers, secretary.

Port Elgin, Ont.—Contract has been awarded by the department of public works, Ottawa, to M. Clairmont, Goderich, for repairs to wharf and partial reconstruction of breakwater. R. C. Desrochers, secretary.

Quaco, N.B.—Tenders will be received until 12 o'clock noon, September 17th, by the department of public works, Ottawa, for reconstruction of eastern breakwater, Quaco (St. Martins), County of St. John, N.B. Plans, etc., offices of district engineers at St. John, N.B.; Halifax, N.S., and at post office, St. Martins, N.B. R. C. Desrochers, secretary.

Regina, Sask.—The city council will purchase tools and equipment, including three soot-blowers and an 18-ft. lathe for the city power house. Estimated cost, $12,691. Superintendent Bull.

Smith's Falls, Ont.—Town engineer is preparing plans and estimates for dredging to a navigable depth that part of the Rideau canal lying between Foster's locks and Nichols' lock and providing docking facilities on the south side. J. H. Moore, engineer.

St. John, N.B.—The following tenders were received for construction of concrete retaining wall and 3-in. tile drain on St. James St. W.: E. A. Farren, wall, $18.70 per cu. ft., drain, 30c. per lin. ft.; Louis Stevens, wall, $16.80, drain, 25c.; George and Simon, wall, $15.90, drain, 30c.; J. H. Burley, wall, $15.70, drain, 8c.; Moses, Tobias and Ferris, wall, $14.79, drain, 15c.; J. Flood and Son, wall, $14.40, drain, 15c.; R. D. Innes, wall, $14.20, drain, 10c.; H. O. Clarke, wall, $13.75, drain, 10c.; Ring and Irons, wall, $12.50, drain, 10c.

St. John, N.B.—Tenders will soon be called for extension of the grain conveyor system to berths No. 14 and 15.

Thorold, Ont.—Tenders will be received until 12 o'clock noon, September 8th, by the department of railways and canals, Ottawa, for placing stone protection on summit level of the Welland Canal, between Thorold and Port Colborne. Plans, etc., at offices of chief engineer, Ottawa, and superintending engineer, St. Catharines. J. W. Pugsley, secretary.

Vancouver, B.C.—An additional dredging scheme, which includes the reclamation of a 60-acre island in the North Arm of the Fraser river, is being considered by the municipalities. This island, if constructed, would be available for industrial sites.

Tenders Called For

MELFORT, SASK.

Electrical Apparatus and Poles, Wire and Line Material

Sealed Tenders, registered and endorsed on the envelope. Tender for (tender bidden on) and addressed to A. H. Williams, Secretary-Treasurer of the Town of Melfort will be received up to September 16th, 1919, for the supply and delivery of the following equipment and materials:—

Tender "A"—For the supply, delivery and erection of switchboard and other apparatus.

Tender "B"—For the supply and delivery of weather-proof wire and line material.

Marked cheque for five per cent. (5%) of the amount of the tender must accompany each bid. The lowest, or any tender, not necessarily accepted.

Plans and specifications may be seen at the offices of the Consulting Engineers, Saskatoon, Sask.; the Secretary-Treasurer's office, Melfort, Sask.; *The Canadian Engineer*, Toronto; and *The Canadian Engineer*, Western Office, 1206 McArthur Building, Winnipeg.

Reconstruction of Water Works at Cobourg, Ont.

Four Electrically-Driven Pumping Units, Each 750 G.P.M. Capacity, on Domestic Service—Gasoline-Engine-Driven Unit Replaces Steam as Standby—Three Mechanical Filter Tanks Operating Under Normal Conditions at Double Rated Capacity

By A. E. DAVISON
Municipal Engineer, Hydro-Electric Power Commission of Ontario

COBOURG, Ont., a town of about 5,000 inhabitants, obtains its water direct from Lake Ontario. The pumping station was originally an electric power plant, to which was added a belt-driven turbine pump for supply of water to the town, with two steam pumps, of the compound duplex type, for fire service.

The system was bought by the Seymour interests when the Trent river was developed. The electrical section of the plant was then disposed of and a layout made of a motor-driven pumping plant and pressure filter system, located in the old building.

The water entered the suction well through a 12-in. intake laid upon the rock bottom of the lake and anchored thereto, and a 14-in. suction pipe with foot valve supplied the pumps from the well. In addition to this, an auxiliary supply was available from six drilled wells adjacent to the station. This water was highly mineralized, a smell of sulphur being distinctly noticeable, and on account of its corrosive quality this source of supply was only used for

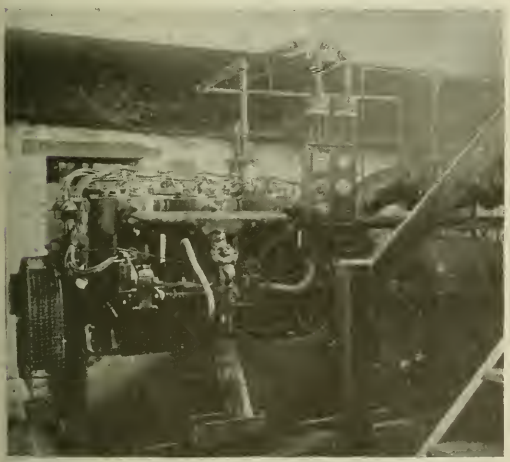

FIG. 1—GASOLINE-ENGINE-DRIVEN FIRE PUMPS

emergency and for clearing the intake of trash and ice which gave trouble in the winter season.

Four pumping units were installed, each of 750 g.p.m. capacity, arranged to operate in parallel for domestic service and in pairs in series for fire service, giving domestic capacity of 1,500 g.p.m. with reserve domestic capacity of the same amount. Pressure for domestic service is from 70 to 75 lbs., and for fire 100 lbs. at the pump-house, excess pressure under fire combination with small demand being taken care of by relief valves.

The filter plant consisted of three horizontal units 8 ft. diameter by 20 ft. long, of extra heavy construction, and with the usual connections for simple back wash. The control end of the filters is shown in Fig. 2. The rating of

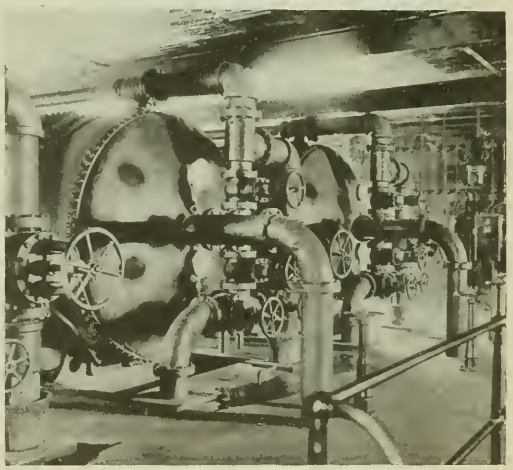

FIG. 2—MECHANICAL FILTER TANKS

each filter is 270 Imp. g.p.m. at 1.67 g.p.m. per sq. ft., which is satisfactory for muddy and contaminated water, but under present conditions, with supply taken off a clean rock bottom over 20 ft. below the surface, the quality of water is so good that the above rate can easily be increased 100%, giving a capacity of 1,600 g.p.m. under normal operation, with further increase during fire demand.

Soon after this installation was made, the town standpipe was wrecked by a fall of ice, and the system has been operated to the present time as a direct pumping proposition, without reservoir.

The location of the station is at a point on the lake shore which receives full force of all storms and there is much ice accumulation in the winter, resulting in excessive turbidity of the water near the shore and the breaking away of section of the intake pipe from time to time, so that when the system was acquired by the Hydro-Electric Power Commission of Ontario, a new intake was necessary to ensure against failure of the water supply and to relieve the

filtration plant of excessive load and constant back washing at certain seasons of the year.

A new intake was completed in 1916, of riveted steel pipe, 25½ ins. diameter, 900 ft. long, laid in a channel blasted in the rock bottom of the lake and back-filled with rock, the pipe ending in a steel intake box of ample dimensions, securely anchored in about 20 ft. of water. A new suction well was blasted in the rock 10 ft. by 30 ft. by 15 ft. deep, and covered by a brick annex to the old building. The suction main was extended to this well and the old well left for the supply of the steam reserve. The cost of the intake and suction well was about $38,000. This was higher than originally estimated, due to the impossibility of maintaining drill boats, dredges and tugs at work in the lake except in unusually fine weather.

At this time an automatic device was installed for coagulant and hypochlorite in place of the usual hand-controlled feed apparatus.

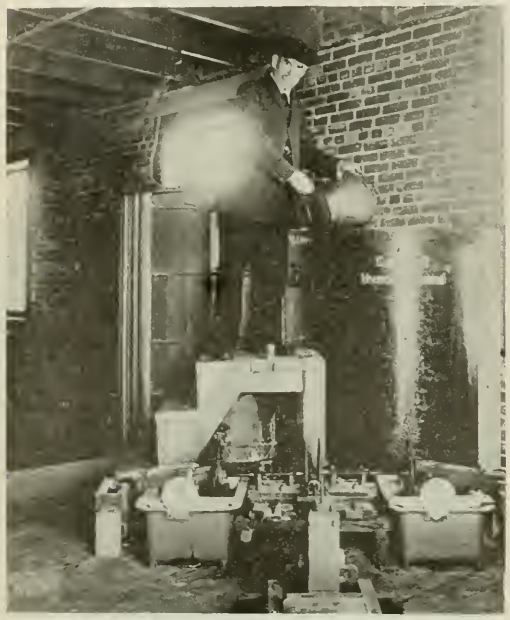

FIG. 3—AUTOMATIC DEVICE DESIGNED BY THE "HYDRO" MUNICIPAL ENGINEERING STAFF FOR FEEDING COAGULANT AND HYPOCHLORITE

The new device is mechanically driven by a turbine placed in the mouth of the intake pipe within the suction well, of sufficient size to operate the device under velocity head only, and with as low a discharge as 300 g.p.m.

The power required being extremely small, the speed of the turbine is proportional to the flow of water in the intake, and the device for feeding each chemical solution consists of a revolving disc on which are mounted small buckets which dip into the solution, the level of which is held constant by float control after the manner commonly obtaining in orifice boxes. The buckets discharge into a trough, from which direct pipe connection is made to the suction well. The speed of the buckets is adjustable over a wide range by friction disc drive from the turbine for any strength of solution or rate of dosing. The device arranged for two solutions is shown in Fig. 3.

Previous to the year 1917, it was necessary to hold steam at 40 lbs. pressure on the boilers as reserve for the steam pumps for fire service, and for occasions when electric power went off. The cost of this reserve becoming serious with the rise in price of coal during the war, it was decided to replace this part of the plant with two gasoline-operated units drawing water from the new suction well, and to abandon the old well and intake.

One of these units was installed about a year ago in place of one of the steam pumps, and consists of a 1,200 g.p.m. pump coupled to a six-cylinder engine, running at 1,500 r.p.m., complete with electric starting motor and storage battery, this battery being maintained in proper working condition by a small generator which can be operated at any time by belt from the coupling of one of the motor-driven domestic pumps. This unit is shown in Fig. 1.

The main gasoline tank is located in the usual manner, underground and outside the building, with the gasoline pump and auxiliary tank in a small concrete annex, an extension shaft and tell-tale passing through the wall for the purpose of operating the pump from inside the station.

The cost of this unit installed was about $7,000.

An automatic valve has been designed for cutting off the gasoline from the engine should the operator forget to do so when he shuts down the unit, in which case a leaking carburetor valve might allow gasoline to escape. This valve is controlled hydraulically from both the suction and discharge of the pump, and operates when the engine stops, independent of pressure on the pump from the town mains.

It has been sought by the above arrangement, and by fire walls and fire doors separating the electrical from the gasoline equipment, to make the gasoline reserve for fire thoroughly reliable and satisfactory when in charge of competent operators.

The total capacity for fire service under 100 lbs. pressure amounts to 3,400 g.p.m., made up of 1,200 g.p.m. for the gasoline unit, 1,700 g.p.m. for the electric units and 500 g.p.m. for the steam plant.

The steam unit is to be replaced with a second gasoline unit, and an additional unit for domestic service is under consideration.

The book value for the filter plant is $8,700, and for the electric pumping plant $9,200.

CANADIAN GOOD ROADS ASSOCIATION

AT a meeting held last Thursday in Toronto, the executive committee of the Canadian Good Roads Association decided that the 1920 congress and exhibition should be held in Winnipeg. Plans were also discussed for an educational campaign for the purpose of stimulating interest in the good roads movement, and to insure that full advantage will be taken of the federal grant of $20,000,000.

Details of the educational campaign will be announced after another meeting of the committee to be held September 25th in Ottawa, but it is understood that this campaign will consist of the use of a limited amount of display advertising, and the preparation of interesting articles for use by the newspapers as reading matter. An office will be opened in Montreal and a staff engaged in order to carry on the work upon a more energetic basis. Contributions will be received from any interested firms or individuals, and it is expected that aid will also be secured from the Dominion government and the various provincial governments.

Regarding the selection of Winnipeg, it is interesting to note that this will be the first time that the congress has gone west of Toronto or Hamilton. Winnipeg was selected for the place of the convention in 1917, but owing to railway congestion and other war-time conditions, plans for holding the convention there had to be abandoned, and it was held in Hamilton instead. These difficulties have now disappeared, and the Manitoba members of the association are enthusiastic about obtaining the convention next spring for their province. Interest in good roads is increasing throughout the west. Vancouver has already requested the 1921 convention.

The executive committee of the association consists of S. L. Squire, Toronto, president; Andrew F. Macallum, Ottawa, first vice-president; Geo. A. McNamee, Montreal, secretary-treasurer; Russell T. Kelly, Hamilton, director; and J. A. Duchastel, Montreal, past president.

PUMPS FOR SMALL WATER WORKS*

By Henry A. Symonds
Boston, Mass.

IN designing a plant for pumping water for a small community, it is usually the case that the per capita cost of operating and maintenance is greater than in the large city plants, and it is important that a careful study be made of the relative merits of the different forms of power available, their adaptability, first cost, and efficiency when operating to do the particular work desired.

It is usually the case that strict economy must be practised in the introduction of these works, and studies relative to first cost have usually been made to bring the cost of the work within the ability of the communities to pay. Not so much attention, however, has been paid to the question of relative efficiency and daily cost of operation, and it frequently occurs that plants are in operation which citizens of the town, and even the water works officials themselves, believe to be highly economical, and that are the reverse. The difference in cost of operation may be so great as to make it good business to pay a much higher price for an economical unit.

Water Power—The early use of power for pumping water in the small-town installations was largely by water power or steam, and it is possible that water power is coming back into use for pumping purposes, but probably through the medium of the hydro-electric plants, as it is not common to find good water privileges so located as to be directly available for pumping from the approved sources of water-supply.

Steam Pumps—Steam has been used for many years very efficiently in many small plants.

Steam Turbines—The development of the centrifugal pump, which has now found so wide a field, was closely identified with the bringing out of the steam turbine.

The Ideal Small Pumping Plant

The centrifugal pump has been known for a great many years, but for a long time after it was invented the difficulty of getting suitable drive with sufficiently high speed retarded the development of successful operation of this type of pump. The real growth of this pump has occurred in the past ten years, during which time the use of the steam turbine and the electric motor with direct connection to the centrifugal pump has brought up the efficiency of the pump to a relatively high stage. At the present time the use of the steam turbine as applied to pumping water is mainly in the large units, and the motor is generally adopted for driving the smaller plants.

The result of the use of steam is, on the whole, satisfactory, but for the small water plants it is subject to the objections that the economical pumping machines with boilers are expensive and occupy much space, and provision for large storage of coal and adequate pumping-station buildings are required, all of which conditions add to the first cost of the plant and are aggravated by the fact that licensed engineers are required to operate such a station.

To-day we consider the ideal small pumping engine that which is economical in first cost, and is self-contained; i.e., operates from a source of power which is part of the engine or at least located in the same station. It is desirable to have it occupy as small space as is practicable, be simple in operation and not require the services of licensed men, easily repaired, quickly started, using fuel which is readily available at all times, and be capable of producing power at a relatively low unit cost.

Electric Motor—Many of the conditions of an ideal plant are met by the electric motor, and the electrical installation has become more and more common. The advantages are: Low first cost; it requires little space; low cost of maintenance; no expert supervision; it is especially well adapted to drive centrifugal pumps with direct connection, which saves friction loss of gears, and prevents noise; it may have automatic control; it may operate during periods of low load at central station, thereby getting lower rates; instant starting; as it has no reciprocating parts, it can be left to operate without attendance better than any other form of drive. The use of electricity has two serious defects in the average municipal plant; namely, it is not self-contained, but depends upon a line of wires and a power plant, usually at a distance, for its operation. For this reason neither one nor two units in a pumping station operated from the same plant are satisfactory to the insurance authorities, as they rightly claim that an accident to the wire line or the power plant will put both units out of use as quickly as one and leave the town or city in an unprotected condition in case of fire.

Attendance the Large Item of Cost

The advocates of the use of motors base their claims of low cost of operation upon the fact that attendance may be a minimum and that this is really the large item in operating small water plants. The writer believes that this argument has considerable merit, and that the improvement in efficiency brought about recently in the centrifugal pumps, and the low cost of the pump and motor, with the advantages above referred to, make this form of pumping plant a very close competitor of, and in some cases it will be found actually to be a better business proposition than, the other types of pumps and engines in spite of the difference in efficiency.

Gasoline Engine—Another form of drive which has been used in some of the small pumping plants is the gasoline engine. This form of power has practically all the advantages above mentioned except cost of operation, and in this it falls down badly, as it is operated upon a fuel of such high cost as to make the operation per horsepower-hour too high for practical purposes in the ordinary municipal water works. However, in plants where an emergency unit is wanted and electricity is not available or desirable for any reason, the gasoline engine may meet the requirements in a satisfactory manner.

Producer Gas—The gas producer as a source of power corresponds to the boiler in a steam plant. It has a great many advantages, and when combined with a proper engine for utilizing the gas to the best advantage may be considered as having most of the requirements of the ideal plant.

Comparative Fuel and First Costs of Various Types of Pumping Plants for Small Water Works

*From the Journal of the New England Water Works Association.

This form of power has been used for some time, and, so far as the writer has record, with good satisfaction in all cases. Gas produced in this way may be used in various types of internal-combustion engines with slight modification. A plant of this kind can be installed at reasonable first cost, is self-contained in so far as the power is generated directly next to the engine itself, and operates at a remarkably low cost upon a relatively inexpensive form of coal. The plant takes up more room than some of the other types, and calls for a larger pumping-station space.

Fuel-Oil Engines—In the writer's experience, in nine cases out of ten fuel-oil engines have proved an ideal installation for plants from 25 to 150 h.p., and for this reason it may be proper to give some extra details regarding this engine. The term "fuel-oil" is here used to mean any oil, from the heavier crude petroleum up to kerosene.

Fuel-oil engines are to-day known under two general heads as Diesel and Semi-Diesel, or surface ignition.

Semi-Diesel Engines

The idea conceived by Diesel is the bringing into compression a mixture of air and oil vapor to a point where heat is generated sufficient to ignite the combination. The compression reached varies from 500 to 1,100 lbs. per sq. in., but when the proper temperature occurs the gases burn rather than explode, and it is the claim of the producers of the Diesel type that this slower burning conserves the power of the gases, and the energy realized is utilized almost entirely in pushing the piston through the length of its stroke. In order to permit of the great pressure produced by this process, the machine must be exceedingly heavy, and the great amount of work which is required to perfect the Diesel engine makes it too expensive for the ordinary requirements of small water-supply plants.

The Semi-Diesel, or surface-ignition engine, on the other hand, gets its power by the explosion of a mixture of air and oil gas in the cylinder under compression around 200 to 300 lbs. per sq. in. While part of the energy is undoubtedly used in the shock against the metal of the plunger and cylinder, the resulting thrust produces motion of the piston, which is connected through the crosshead, or directly to a crank shaft which gives the motion to the driving pulley or gear.

The Semi-Diesel seems to meet all the ordinary requirements of the ideal engine described above, and while the first cost of this engine is considerably greater than that of the gasoline engine or the electric motor, the operating costs are so low that this outweighs in most cases the advantages of the low first cost of the other machines.

Poor Fuel Oils Satisfactory

In the types which are considered as small pumping outfits, designed to pump the water for communities of from 1,000 to 10,000 inhabitants, the engines required ranged from 25 to 150 h.p., but in the writer's opinion there is a large field for a still larger oil engine, and there are some machines now being produced that show wonderful efficiency in operation. They are of the Semi-Diesel type, but are able to operate on the poorest grade of fuel oil, and even tar products which have to be heated before it is possible to get them into the cylinders. The oil used runs as low as 18 degs. Beaumé, while in the smaller machines—that is, below 60 h.p.—the writer knows of good results with oil heavier than 26 degs. Beaumé, and with 25 to 35 h.p. engines kerosene or light oils of that grade have seemed to give the most satisfactory results. Pre-war prices ranged from 2 cents to 7 cents for the various grades.

The ordinary time of starting with fuel oil is from 12 to 18 min., but engines of this type may be equipped with apparatus which permits of instant starting by electric ignition and gasoline, the fuel oil being turned on after a few minutes, without interruption of the operation of the engine. This latter contrivance is of especial value where but little storage of water is possible and pumps have to be operated in case of fire, as the delay in heating the cylinder head may be serious if the supply of water is not available.

It is claimed by the advocates of the electric motor, in comparison, that the motor requires little attendance, while the oil engine calls for constant supervision. This claim is not entirely substantiated in practice, for many of the oil plants are operating for long periods of time without attendance. This of course assumes that there are duplicate units which will take care of any fire hazard if repairs are necessary. It should also be considered that constant attendance does not eliminate many of the breakdowns.

Perhaps the most satisfactory combination that can be installed for a small pumping plant for general municipal needs is made up of two duplicate units, of which it is probable that the fuel-oil engine meets the needs fully as well as any other drive which has been developed up to this time.

One advantage, of considerable importance in some cases, that steam machines have over most of the other types is in the varying of speed in operation. The speed in the electric motor and of the internal-combustion engines is variable only to a small extent, except by change gears or belt pulleys, and it is sometimes necessary to pump to waste or through a bypass back into the suction, an uneconomical process, in order to keep the rate of delivery as desired.

Comparison of Costs

The writer had occasion, a short time ago, to make a comparison of different types of pumping plants, to determine which plant would best meet the needs of a community. In connection with this, the results of investigation of different units were tabulated and are given on page 289. The figures are not to be considered as exact, either of operation or first cost, but are obtained by using quotations and guaranteed efficiencies by the manufacturers of the different lines of machinery. These figures were also taken before the extreme rise of prices which occurred since the United States entered the war, and, while they are far above the averages of five years ago, it is probable that they are nearer what we may expect in the next few years than pre-war prices.

WILLIAM ARMSTRONG RETURNS TO CANADA

WILLIAM Armstrong, who was formerly Canadian representative for a number of English manufacturers, has returned to Canada after four years of war work, and is again acting as Canadian agent for several prominent overseas firms. When war was declared, Mr. Armstrong happened to be in Vancouver. He left for New York and sailed for England, where he enlisted as a lieutenant in the admiralty, and was assigned to engineering duties on board one of the warships. Shortly afterwards, however, he was appointed technical officer in charge of mine production, and when the armistice was declared he held the rank of acting-commander. Under Mr. Armstrong's direction approximately 3,500,000 mines were manufactured, largely by electric welding.

The agencies which Mr. Armstrong has undertaken are as follows:—

Quasi-Arc Electric Welding Co., covered electrodes and resistances for use in electric welding; Sturgeon Centrifuge Co., centrifuges of various types for clay drying, sewage disposal, etc.; Hick, Hargreaves and Co., condensers, Diesel engines and steam engines; Jos. Booth Bros., Ltd., electric overhead travelling cranes; T. F. Braime and Co., seamless specialities in all metals; Yeadon, Son and Co., briquetting machinery; Head, Wrightson, Ltd., colliery apparatus and blast furnace plant; Sankey and Son, Ltd., steel wheels for automobiles; British Electric Vehicles Co., electric trucks for conveying baggage at railway terminals, handling shipments from warehouses, etc.; Jos. Carter (Stalybridge), Ltd., rubber-working machinery.

The president of the Draftsmen's Association, which has been organized in Toronto, is Geo. H. Rix, of the C.N.R. staff. The secretary is Arthur E. Fetherstonhaugh, architect, 234 Kingswood Rd., Toronto. Meetings will be held the second and fourth Fridays of each month during the fall and winter.

STREAM FLOW AND PERCOLATION WATER*

By Samuel Hall
Assistant Water Engineer, Belfast

THE author, many years ago, commenced investigations of the conditions which govern and control the ever-varying flow of streams and rivers, conceiving that, even were no definite laws established, he might gain a better knowledge of the subject, and information of practical value. The author considers that the agreement between data and facts from widely different sources is such as to fully warrant the statements made in this paper. The subject is treated broadly, and in order to make it clearer many well-known conclusions are repeated.

Fig. 1 is a flow curve showing inconstant rates of discharge for a period of 24 days, and some features characteristic of probably all stream flow curves, the most noticeable being the "peaks" following rainfall, showing immediate increase of flow attributable to surface run-off. Another feature is the slowly falling parts obtaining in rainless periods, when the flow is that of percolation discharge alone. The curve shown represents the flow from a mountain catchment of between 2,000 and 3,000 acres in extent, and is taken from automatically recorded diagrams of depth of

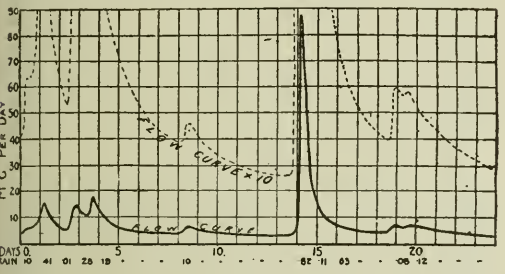

FIG. 1—STREAM FLOW CURVE

water over a weir. It shows quick "run-off" and very marked, yet not exceptional, variations of flow.

Before comparing "peaks" of different streams, it will be interesting to compare those of one stream. They are greatest in proportion to rainfall when the surface soil is moist, always large in winter and after wet weather gradually smaller as summer advances, and smallest near the end of a long period of drought, when they contrast greatly with those of other periods. The rate of rise to a peak, when other conditions are the same, is a rough measure of rainfall intensity, which affects the height of the peak and flood rates. The falling part of the peak curve is generally slightly "slower" than the rising part, and becomes still slower as it descends. It indicates the rate of surface drainage after rain has ceased, and appears to be of some approximately regular form, but is, of course, modified by the amount of percolation discharge. The gently falling and lowest parts of the curve due to percolation discharge are generally gradually higher from the autumn and lower from spring to the end of summer, being lowest at the end of a long drought. One characteristic of these parts is the steady fall of the curve, showing not only that the rate of flow decreases, but that its rate of decrease also diminishes; in other words, the curve gets flatter from day to day throughout a rainless period. Towards the end of a drought the diminution is so small that the curve might appear to have become a horizontal line, yet examination of a greater length of curve will suffice to show such a conclusion is wrong; but it appears probable that a slowly diminishing flow might be continued during perhaps a year of further absolute drought. Some streams in these islands occasionally run dry, yet the larger streams and rivers have substantial discharges in droughts which are but of short duration compared with those which occur in some other countries. Another feature to which attention must be drawn is that the position of these parts of the curve is raised after every peak occurs. To make this clear, let us imagine a prolongation of the curve obtaining before the peak, on the line it would probably have taken had the rainfall not occurred. The produced curve would, apparently in every case, lie some distance below that which actually obtains after the peak, and the amount of difference between the produced and actual curves appears to be roughly proportionate to the extent of the peak. It seems to be clear that not only has there been a large immediate yield as shown by a peak, but that the stream has gained in "staying power." The conclusion drawn is that new supplies of percolation water have increased the amount in store, with the reslut of increased discharge. The effect of frost is, in general, precisely the same as that of absence of rain. Frost does not affect the percolation discharge, except perhaps where such occurs as small surface springs, but it holds up surface "run-off." Snow, of course, does not affect flow until thawing takes place.

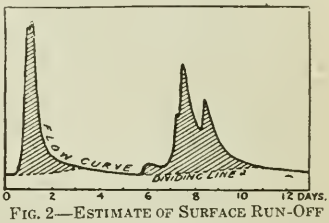

FIG. 2—ESTIMATE OF SURFACE RUN-OFF

In comparing curves of different streams it may be seen that the slope of the ground is a factor which affects the rates of rise and fall, and also the size of the "peaks," no doubt because less slope and slower "run-off" allows surface water to remain for a longer period under percolation influences. The length and slope of the stream courses are factors influencing chiefly the shape of the peaks, because after water has supplemented the flow in the upper reaches of the stream some time elapses before the effect is recorded at the gauging point. This time, roughly determinable, is a matter of hours for small streams, but of days for large rivers. Every stream course has a slight temporary storage effect, which is increased where the banks are permeable and extensive.

In order to form a rough idea of the extent to which the nature of the drainage area affects the peaks, we may assume the case of a river fed by a number of streams of similar drainage areas at various points. The effects of spates on each stream would be recorded at times, varying roughly according to the distance of the points of confluence from the gauging station. Tracing the flow curve of one stream, and altering the time for each so that if superimposed the peaks would show one after the other, the sum of these stream flow curves representing the total flow of the river, would obviously show less rates of rise and fall, and a less maximum rate in proportion to the total drainage area. Though other factors might modify the curve, the logical conclusion is that increase of size means flatter peaks and smaller maximum or flood rates in proportion to the area, whilst the converse holds for smaller areas.

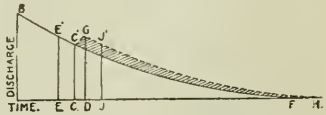

FIG. 3—TANK DISCHARGE CURVE

"Dry weather flow" is used by various engineers to mean either minimum known flow, or that for one year (average), or occasionally a supposed irreducible and constant rate which would obtain under any exceptionally adverse conditions. As a term so variously interpreted cannot lead to anything but confusion, what is meant should be expressed in other words. The minimum rate of flow is seldom the same in any different years, and any particular minimum only holds good till a lower one is recorded.

The sources of supply due to precipitation can be classed as: (1) Surface run-off; and (2) percolation discharge.

*From a paper read before the Institution of Water Engineers of Great Britain.

The chief source of deficit between rainfall on the area and resultant flow is evaporation loss. Another source of deficit is the loss of percolation water, which is inevitable, though it might be small in amount; but, on the other hand, this loss might be more than compensated for by gains of percolation water from sources outside the topographical drainage area.

(1) *Surface Run-off.*—That part of the rainfall which falls on the water surfaces as a "direct contribution" to the stream is measurable by the product of rainfall and water area. It causes the first upward turn of the curve at a peak; normally small in amount, it becomes a greater proportion of peaks towards the end of a period of drought, and might at such times be the only benefit from rainfall.

Some of the factors affecting surface run-off have been already mentioned. Absorption and percolation are factors which are probably not of equal effect over the whole of the drainage area, and also vary according to weather conditions. Surface run-off will occur when and where the rate of rainfall exceeds the rate of absorption until the surface soil is saturated; then it depends upon the difference between rates of rainfall and percolation.

The proportion of rainfall yielded as surface run-off is high when the ground remains frozen, and is generally very small in summer, sometimes very large, however, after the ground has been "baked," but whether this is actually due to the "baked" condition of the soil or to greater intensity of

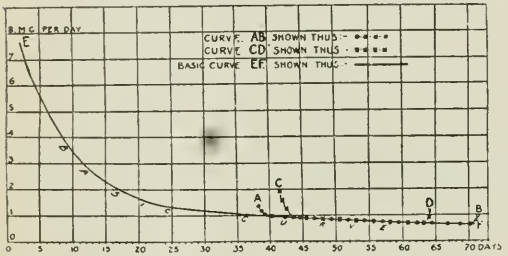

FIG. 4—BASIC CURVE OF PERCOLATION DISCHARGE

rainfall, such as obtains in thunder showers, has not been satisfactorily determined. The author has observed in ground over clay subsoil that extensive and frequent cracks develop during droughts, and it is questionable whether such cracks, at times two inches in width and more than a foot in depth, would not counter-balance the effect of baking the ground.

Whilst the ground is under the effect of recent rains, a subsequent rainfall produces a greater result in the amount of run-off. A few hours after rainfall has ceased it would be very difficult to detect, on the gathering ground, any indication of surface run-off (except where flooding has occurred), though it is quite noticeable during heavy rains from the newly formed streamlets appearing in ill-formed and miniature valleys in the drainage area.

In estimating the time at which it becomes *nil* or negligible, the fact of thin films of water being almost unnoticeable should be taken into account, and the author's estimate of the time which might elapse before the surface water has reached a stream course is given as seldom more than 48 hours, but variable according to the amount of rainfall, percolation rate, and surface slope. On this assumption dividing lines have been inserted in the flow curve in Fig. 2, to show an estimate of the increase of flow due to surface run-off; this is shown by the cross-hatched portions. By treating all the peaks in the same manner, an estimate of the yearly total of surface run-off can be made. The amount of flow, as shown by the low-lying parts of the curve, and up to the dividing line or lines is likewise an estimate of the percolation discharge. Where rainfalls succeed one another, the guide to the insertion of the dividing lines should be the estimate of percolation discharge, which has but a slowly increasing rate, and the dividing lines must obviously commence at a part of the curve which indicates percolation discharge alone. In the case of large rivers, allowance for the time taken in flowing down the river will be necessary, but percolation discharge will be the best guide for estimating purposes. It is not, of course, possible to determine accurately what proportion is due to the two intermediate sources of supply, but it will be noted from Fig. 2 that were the time of 48 hours altered to 36 or 60, it would not affect the estimate very materially.

The area from which surface run-off occurs is obviously defined by the natural water partings, but it must be noted that this area is not necessarily identical with the percolation drainage area.

Conditions Affecting Percolation Discharge

(2) *Percolation Discharge.*—Of percolation discharge there is visible and irrefutable evidence in the existence of springs discharging percolation water at the surface of the ground. There are also subaqueous springs discharging into the beds of streams, rivers and the ocean less apparent and likely to escape notice. There are doubtless similar discharges of percolation water which, from finding easy passage through alluvial deposits to open water, are perhaps outside the possibility of detection. Considering that almost all rocks are fissured, and that the beds and banks of streams are, as a general rule, extensive alluvial deposits, it is most probable that a surface discharge occurs as an exception rather than a rule. There is no better evidence of the temporary storage of considerable volumes of percolation water than stream flow when the surface soil is parched, for at such a time the whole of the flow is obviously from such sources. So far as stream flow is concerned there is no need to make any distinction between visible spring flow and other percolation discharge, as the laws which apply to one apply with equal force to the other, and to percolation discharge as a whole.

The geological conditions of the drainage area affect percolation storage and discharge, yet in the author's opinion physical conditions have often greater influence. For example, the same bed of grit may be in one locality very much fissured, and in another considerably less so, and such differences mean like differences in storage capacity. Limestone, granite, other compact rocks, and also alluvial deposits, likewise differ in storage capacity in fissures and interstices. The rate of discharge also depends probably more on physical than geological conditions, and the greater width of an outlet for percolation water might be merely accidental. The volumes of water which can be absorbed by compact rocks after they have been heated to dryness is very considerable; yet this should not be taken into account, as all the deep subsoil rocks are, and remain, moist whilst *in situ*, and the amount they can retain, despite the force of gravity, is most probably constant. For these reasons the author strongly inclines to the belief that it is the fissures, and not the compact rock, which yields the percolation discharge. There will doubtless be cases where the water percolates through compact rock; but where fissures occur, they provide much quicker drainage for the bulk of percolation water.

Percolation and Hydraulic Laws

It is not proposed to consider the subject from a geological point of view, but to consider how far percolation discharge is subject to known hydraulic laws, and in order to do that it is necessary to consider the physical conditions which affect storage and discharge. Percolation water, having passed through surface soil into permeable strata, trickles downwards through interstices and fissures until its downward progress is stopped by impermeable strata, or until it reaches an existing water surface. Its course afterwards, in either case, is most probably like that of water in open channels, to which fissures and large interstices in the strata are a rough parallel. Each fissure or miniature channel has its rate of discharge and a hydraulic gradient inseparably related to the discharge rate. The hydraulic gradient is, of course, the water surface. The surface of percolation water in a network of fissures and interstices, assumed continuous through intervening rock, has been termed the surface of saturation, but is more generally called sub-soil water level. It is really a network of hydraulic gradients, and for any particular position there is a related flow, or rate of discharge. Its slope depends partly on the size and

extent of the fissures, which, being usually of small size, will have steeper gradients than those which we usually associate with open channels. The surface of saturation is not level; it bears no relation to the surface of the ground, but inclines towards the outlets for percolation water, and it coincides with free water surfaces. Its position is not fixed, but is slowly altered by discharge and supply; and should supply disturb the hydraulic gradients throughout the surface of saturation, there is a natural tendency to settlement to some position which corresponds throughout with a particular discharge rate.

The conclusions are that where part of the rainfall can percolate to the deeper subsoil, a surface of saturation is formed in the fissure and interstices of the rocks, and that there is a rate of percolation discharge corresponding to each position of the surface of saturation, and such conditions will generally obtain. Where clay immediately underlies the surface soil, discharge conditions are perhaps slightly different, but the author has not had an opportunity of investigating such a case.

Subsoil Storage Reservoirs

The conditions of storage of percolation water may not always be the same as those mentioned, for it is quite possible there are what might be termed natural subsoil, but leaking storage reservoirs, the discharge from which might be considered as from a reservoir outlet pipe. In such a case hydraulic laws would apply, and the discharge would have its related "head" and its hydraulic gradient. The author has evidence in two cases of excavations which pointed to the existence of leaking subsoil storage reservoirs. In one of these cases the volume of water was large, and the annual variation of water level small, sufficient to show that if leakage did occur it could have been continued for at least a year of absolute drought.

In considering how the available quantity of percolation water might be approximately determined from percolation discharge, it will materially assist if we first consider conditions affecting the discharge from a tank. The discharge rate or flow curve from a pipe outlet from an irregularly shaped tank would be of some such form as shown by the firm line E^1F in Fig. 3, the rate of discharge at any time being represented by an ordinate of the diagram at that time; thus E^1E represents the rate of discharge at the time E. Having the whole diagram, the total discharge is measurable; the total discharge represents the "storage capacity" of the tank, which is thus determined by means of the flow curve alone. Let us call this curve (E^1F) the basic curve, and note that any rate of discharge denotes a related position of the water level in the tank, and some corresponding amount of storage. It is quite obvious that if the tank were again filled, the basic curve would be reproduced; and if the rate of discharge at a given time be ascertained, the subsequent rates of flow, or the total available flow, can be foretold from the basic curve, no actual observations of the water levels in the tank being necessary. When a fresh supply of water is poured into the tank, it results in a corresponding alteration in the flow curve, which repeats some part of the basic curve after the supply is stopped, and by means of the basic curve the amount of supply can be determined.

Hydraulic Similarity

This case is illustrated by the dotted line in Fig. 3, which shows the effect of a fresh supply. After the supply has been stopped, the flow curve GH is a repetition of a part of the basic curve. The rate DG being the same as EE^1 at some point on the basic curve, the curve GH is the same as the curve E^1F. It is obvious that the amount of the fresh supply has caused the increase of flow shown by the shaded portion of the diagram, and the difference between the total discharges as shown by the curves C^1GH and C^1F obviously shows the total amount of the fresh supply. The latter is also measurable in another way; the ordinates EE^1 and DG are equal, and show that the quantity of water in the tank at the times E and D was the same; hence the total discharge between the times E and D as shown by the curve E^1C^1G was the net gain, or the amount of fresh supply. Similarly, by locating the time J when the ordinate JJ^1 is equal to CC^1, the total discharge between the times C and J, shown by the curve C^1GJ^1, is also equal to the fresh supply. The last mentioned is the method which appears most convenient for ascertaining the amount of gains accruing from rainfalls.

It must be borne in mind that it is a short method of measuring total gain, which, as shown by the shaded portion in Fig. 3, causes an increase of flow over a considerably longer period than that denoted by the time CJ. The aggregate percolation discharge from a drainage area is really a number of discharges from different ill-defined and overlapping areas, and may be likened to that from a series of tanks having various rates of discharge and various rates of supply, making it doubtful whether the principles would hold good; yet the average rate of supply to each tank governs the rates of discharge to a considerable extent; thus, when supplies are small low discharges prevail, and the converse of this also holds good.

The supply to percolation storage is "available rainfall," the governing influence of which is best illustrated by the fact that streams and rivers throughout the country show lowest flows at about the same times. It is now proposed to apply the above-mentioned principles, which are based upon well-known hydraulic laws, to percolation discharge, which is believed or assumed to be subject to the same laws, and should tests indicate agreement, it might reasonably be presumed that the assumption is correct.

Basic Curve of Percolation Discharge

Let us now suppose that after a period of considerable percolation the natural storage of percolation water is as great as it can be, that the stored water receives no further supply, but is exhausted by discharge. The flow curve obtained during this period, hereafter called the "basic curve of percolation discharge," would be a parallel to the basic curve of the hypothetical tank discharge; and whenever similar conditions obtain, some parts of the basic curve should be reproduced between times of fresh supplies. Let us now test the actual stream flow curve to see whether or not it does behave in this manner; for if it does, we might, from these reproduced parts, construct a considerable length of the basic curve. The method of testing is as follows: Reproduce on a diagram the flow curve shown during an absolute drought in which the lowest flow is measured, as AB in Fig. 4. (The curve in that figure is shown by a series of dots for the sake of clearness.) Reproduce a second drought flow curve in which the second lowest flow is measured, as CD, so that the ordinate showing the second lowest rate coincides with the ordinate of the first curve showing the same rate. Then, if the principles apply, a length of the second curve will coincide with a length of the first, and the coinciding portions show a length of the basic curve. Similarly, other drought or rainless period lengths of the stream flow curve can be reproduced until the greatest available length of basic curve is obtained. It is recommended that a tracing of the basic curve be then applied throughout the stream flow to test whether the flow curve in all rainless periods reproduces a part of it. The author tested in this manner the basic curve as shown by EF in Fig. 4, and found that the discrepancies were so slight that they may have been due to variations of evaporation from the stream surface. For accuracy, fine readings are necessary, particularly where the flow curve is almost flat, but in two cases the author obtained basic curves where only rough daily gaugings were given, and these showed agreement with actual flow in rainless periods as nearly as it was possible to ascertain. The stepped curve of daily gaugings was replaced by one passing through the middle points of the horizintal portions. The basic curve as shown by EF in Fig. 4 agreed with the stream flow curve from three to five days after rainfall had ceased; towards the end of this period the difference between the two was slight, but such as to shorten the times at which the basic curve was applicable; and this period was in another case apparently from four to as much as ten days, and in each case varied as the yield from rainfall was smaller or larger.

It will be obvious that the basic curve of percolation discharge is not capable of application at times when there is both surface run-off and percolation discharge, and that

its use would be strictly limited to the times at which the flow curve of the stream has assumed the basic curve form, and it is important that this should be noted. When the former has assumed agreement with the latter for even a short distance, the basic curve can be used, in precisely the same manner as that obtained from the hypothetical tank discharge, to foretell subsequent rates of flow which would occur in the absence of fresh supplies to the limit of minimum flow previously measured, and to state the time at which that limit would be shown; also to determine the volume of percolation water available in the meantime. Where times of application permit, the fresh supplies form periods of rainfall, *i.e.*, the available percolation supplies, and occasionally that due to a particular rainfall, also the difference between the respective amounts of available percolation water in store at different times, can be determined. It may be noted that the length of the basic curve was determined only to certain limits, but this fact does not prevent its use. An estimate of its continuation could be made for the purpose of determining probable minimum flow under worse conditions, but otherwise would not be necessary.

When a tracing of the basic curve is applied to a flow curve at a time before a peak, to show how the latter would have continued in the absence of rain, the difference between the two curves shows the increase of flow which the rain has caused. So much of the increase as is due to increased percolation discharge would be of similar form to the shaded portion of Fig. 3. The maximum benefit from this source is shown to occur a short time after rainfall, but the benefit continues for a very long period (it might be contended, forever) at a slowly decreasing rate. As a corallary, it might be expected that the total percolation discharge at any time depends upon the amount of percolation which has obtained during many preceding months, and the effect of percolation during a particular month is reflected most largely in the next month, and to a less and less extent in each succeeding month. Examinations of many flow curves have confirmed this fact.

(Concluded in the next issue)

BRITISH ENGINEERING STANDARDS REPORTS

CAPT. R. J. DURLEY, secretary of the Canadian Engineering Standards Association, announces that a stock of a number of the most important publications of the British Engineering Standards Association has been received at his office, and can be obtained by any interested person upon application to him at Room 112, West Block, Ottawa. The accompanying list does not include all publications of the British Engineering Standards Association, but covers those of recent issue. Copies are for sale at twenty-five cents each excepting for the last-mentioned report (No. CL3,750) which is fifteen cents, these prices being net in all quantities. Orders for copies should be accompanied by postal note or money order payable to the Canadian Engineering Standards Association. Following is Capt. Durley's brief description of the publications now in stock:—

Report No. 15-1912. Revised August, 1912. *British Standard Specification for Structural Steel for Bridges, etc., and General Building Construction.*—This report covers process of manufacture, quality of finished steel, tensile tests, bending tests, tests on rivets, chemical analysis, inspection and other conditions.

Report No. 63-1913. *British Standard Specification for Sizes of Broken Stone and Chippings.*—This specification was formulated as a result of conferences between the quarry owners and road authorities and gives standard nomenclature, definitions and methods of measurement for broken stone and chippings.

Report No. 65-1914. *British Standard Specification for Salt-Glazed Ware Pipes.*—This report contains tables of dimensions and particulars regarding sockets, grooving, glazing, permissible variation in thickness and diameter, and methods of testing for strength and absorption.

Report No. 21-1909. Revised November, 1909. *Report on British Standard Pipe Threads for Iron or Steel Pipes and Tubes.*—This report gives definitions and tables of dimensions for British standard pipe threads. In this system the Whitworth form of thread is employed, but fine pitches are used, and both parallel and conical screw ends are provided for.

Report No. 44-1909. *British Standard Specification for Cast Iron Pipes for Hydraulic Power.*—Provision is made for two classes of this pipe, together with bends, tees and special castings. Class A: Working pressures from 700 to 900 lbs. per sq. in. Class B: Working pressures from 900 to 1,200 lbs. per sq. in. The specification covers quality of material, permissible variation of weight, marking, testing, inspection and tables of dimensions and weights.

Report No. 37-1919. Revised January, 1919. *British Standard Specification for Electricity Meters.*—This specification is intended to apply to the purchase of new meters, governing their sale by the manufacturer to the purchaser. Requirements for meters up to the largest sizes in use as well as for three-wire and three-phase meters are included. The electrolytic type of meter is not dealt with. The specification gives standard definitions and provisions regarding external characteristics, insulation, labels, standard method of marking, registering, mechanism, minimum running current, permissible limit of error and rate of registration, tests, precautions necessary in erection and other particulars.

Report No. 41-1908. *British Standard Specification for Cast Iron Spigot and Socket Flue or Smoke Pipes.*—This specification gives a schedule of dimensions and weights, with full size sections, for light cast iron spigot and socket pipes suitable for flue or smoke pipes.

Report No. 45-1917. Revised September, 1917. *Report on British Standard Dimensions for Sparking Plugs for Internal Combustion Engines.*—This report covers external dimensions only, the form of thread used being a metric thread having a 60 deg. angle. Tolerances on full diameter, effective diameter and core diameter for the thread on the plug and in the tapped hole are given, together with external dimensions of the complete plug and standard nomenclature of sparking plug parts.

Report No. 10-1904. Revised July, 1918. *British Standard Tables of Pipe Flanges.*—This report gives the British standard dimensions for pipe flanges for steam and water piping for low pressures and high pressures, dimensions of welded-on flanges for pipe lines for working steam pressures of 125, 225, and 325 lbs. per sq. in., dimensions for short flanged bends and tees of cast metal for pressures up to 325 lbs. per sq. in. and dimensions for long bends of wrought iron and steel.

Report No. 46-1909. *British Standard Specification for Keys and Keyways.*—The specification covers material, tests, definitions and tables of dimensions, for three classes of key: (a) Parallel sunk key; (b) taper key; (c) taper sunk key.

(Concluded on page 302)

Robert Weddell, a well-known contractor, died last week at his home in Trenton, Ont. Mr. Weddell's firm have been the contractors for a number of water-front improvements at Toronto, including the construction of the western channel and repairs to the intake.

The new million dollar laboratory of the United States Bureau of Mines will be formally opened in Pittsburgh, Pa., the end of this month. An elaborate programme of tests, visits of inspection, demonstrations of all kinds, etc., has been arranged for September 29th and 30th, and October 1st, and representatives of various universities and technical associations have been invited.

At the National Industrial Conference, which opens next Monday in Ottawa, the Association of Canadian Building and Construction Industries will be represented by: Fred Armstrong, Toronto; Col. J. A. Little, Port Arthur; H. T. Hazelton, Winnipeg; E. R. Reid, St. John, N.B.; G. H. Whitlock, Moose Jaw; and J. P. Anglin, Montreal. These gentlemen will be glad to receive any information or suggestions which will assist them in the discussion of the questions that will come before the conference.

PRESSURE RISE CAUSED BY GRADUAL GATE CLOSURE

By Norman R. Gibson
Hydraulic Engineer, Hydraulic Power Co., Niagara Falls

(Continued from last week's issue)

In the foregoing analysis no account has been taken of the effect of frictional losses of head in the penstock. As the velocity in the penstock is gradually destroyed, the friction head is gradually recovered and is added to the net head, producing discharge through the turbine gates.

Derivation of Formulas with Friction Included:—

In any penstock the total frictional losses may be assumed to be proportional to the square of the velocity of flow, and may be represented by a coefficient, F, such that FV^2 = total loss in feet of head for a velocity, V. The velocity head recovered at any time in the first interval, therefore, is $FV_0^2 - FV_{t_1}^2$. This head must then be added to the sum of $H_0 + h_{t_1}$, in determining the relation between velocity, gate opening, and head, as given by Equation (6).

Thus:—

$$V_{t_1} = (1 - t_1/T)B_0(H_0 + h_{t_1} + FV_0^2 - FV_{t_1}^2)^{1/2}$$

Squaring:—

$$V_{t_1}^2 = (1 - t_1/T)^2 B_0^2 (H_0 + h_{t_1} + FV_0^2 - FV_{t_1}^2)$$

Collecting:—

$$V_{t_1}^2[1 + (1 - t_1/T)^2 B_0^2 F] = (1 - t_1/T)^2 B_0^2 (H_0 + h_{t_1} + FV_0^2)$$

Solving and multiplying numerator and denominator by (a/g):—

$$V_{t_1} = \left\{ [(a/g)^2(1 - t_1/T)^2 B_0^2 (H_0 + h_{t_1} + FV_0^2)] \div [(a/g)^2 + (a/g)^2(1 - t_1/T)^2 B_0^2 F] \right\}^{1/2}$$

Substituting S_{t_1} for $(a/g)^2(1 - t_1/T)^2 B_0^2$,

$$V_{t_1} = \left\{ S_{t_1}(H_0 + h_{t_1} + FV_0^2)/[(a/g)^2 + S_{t_1}F] \right\}^{1/2} \quad ...(11)$$

TABLE 4—BY FORMULAS

Data: L = 820 ft. V_0 = 11.75 ft. per sec. H_0 = 165 ft. T = 2.1 sec. a = 4,680 ft. per sec. Friction neglected.

5¾	0.0381	216.95	0.7446
6	0.0	216.67	0.0

Inserting this value of V_{t_1} in Equ. (5) for h_{t_1}, then

$$h_{t_1} = (a/g)V_0 - (a/g)\left\{ S_{t_1}(H_0 + h_{t_1} + FV_0^2)/[(a/g)^2 + S_{t_1}F] \right\}^{1/2}$$

Solving for h_{t_1} in the same manner as that used in obtaining Equ. (7), and substituting R_0 in place of $(a/g)V_0$, and Z_1 in place of $(a/g)^2 S_{t_1}/[(a/g)^2 + S_{t_1}F]$, then:—

$$h_{t_1} = \tfrac{1}{2}\left\{ (2R_0 + Z_1) \pm [Z_1^2 + 4Z_1(R_0 + H_0 + FV_0^2)]^{1/2} \right\} \quad ...(12)$$

In a similar manner, the equation for h_{t_2} is obtained by adding $(FV_0^2 - FV_{t_2}^2)$ under the root sign in Equ. (9) and inserting the resulting value of V_{t_2} in Equ. (8). Without performing the operations, which are similar to the above, the result may be written down at once.

$$h_{t_2} = \tfrac{1}{2}\left\{ (2R_{t_1} + Z_2) \pm [Z_2^2 + 4Z_2(R_{t_1} + H_0 + FV_0^2)]^{1/2} \right\} \quad ...(13)$$

Where $R_{t_1} = (a/g)V_1 + h_1 - C_{t_2}$

$$C_{t_1} = (2a/g)(V_0 - V_{t_1})$$

$$Z_2 = (a/g)^2 S_{t_2}/[(a/g)^2 + S_{t_2}F]$$

and $S_{t_2} = (a/g)^2(1 - t_2/T)^2 B_0^2$

Similarly, the value of h, at any time in any interval, may be found.

When the gate motion is not uniform, the value S_t has to be made equal to $x^2(a/g)^2 B_0^2(1 - t/T)^2$, where x is a constant or variable coefficient, which may be determined by

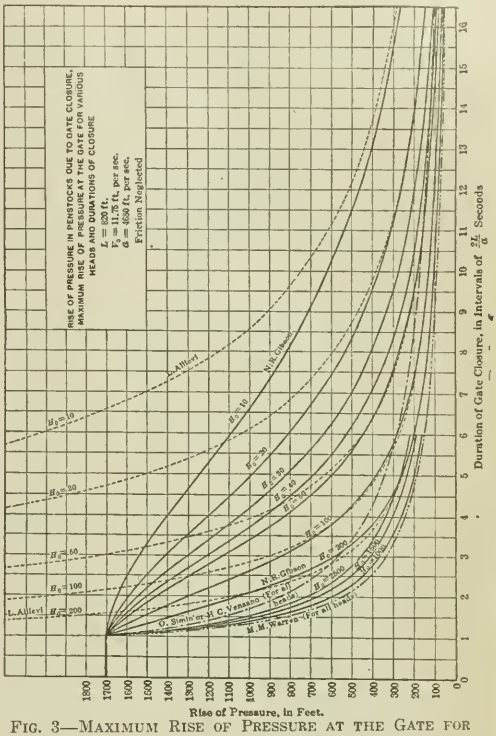

FIG. 3—MAXIMUM RISE OF PRESSURE AT THE GATE FOR VARIOUS HEADS AND DURATIONS OF CLOSURE

plotting the curve of gate opening on a time base. For uniform motion, the curve would be a straight line, the ordinate of which, at any time, t, is $(1 - t/T)B_0$. For any other than uniform motion, the ordinates of the straight line would be multiplied by the constant or variable, x, which, if the motion varied in a regular manner, might sometimes be expressed in terms of t, either graphically or analytically, from the known relation between the governor movements and the

gate opening. If the motion were not regular, a graphical solution only could be obtained.

Tables 4 and 5 show the values of h_t obtained by using the formulas in the examples worked out by arithmetic integration in Tables 1, 2, and 3.

It should be noted here, by way of caution, that, in calculating the value of h, the two terms inside the larger brackets of the foregoing formulas are frequently so large and their difference so small as to make it necessary to perform the work by logarithms. The correct result cannot be obtained in such cases by using an ordinary 10-in. slide-rule.

It is now interesting and instructive to compare the results given by the foregoing formulas with those given by other formulas which have been proposed to determine the rise of pressure caused by gradually stopping the flow of water in pipes. For this purpose Fig. 3 has been prepared. There are three such fundamentally different formulas known to the writer, namely, those of L. Allievi,* M. M. Warren,† and H. C. Vensano‡.

The formula by Allievi gives the maximum excess pressure caused by stopping the flow of a column of water, assumed as an incompressible fluid, moving in an inextensible pipe, and neglecting the effect of friction. R. D. Johnson,§ A. H. Gibson,¶ and W. F. Uhl,‖ have each presented a similar formula, with different nomenclature and somewhat differently arranged, but all give the same result as Allievi's formula. Mr. Johnson has also presented a method of determining the pressure-time curve resulting from the same assumption,** and A. H. Gibson has shown how friction may be taken into account by successive calculations.***

The limitations of the Allievi formula are well known to these authors, as they specifically refer to them; they are known, also, no doubt, to many others who use that formula, because it is readily seen that, for zero duration of closure, the formula gives an infinite pressure rise, and this cannot be so because the finite value of maximum water-hammer, for instantaneous closure, has been proved by Professor Joukovsky. Allievi's formula takes into account the effect of the net head on the phenomena that occur during closure. In Fig. 3, there are shown in dotted lines a series of Allievi curves for various heads, and, for the data assumed, these show the maximum rises of pressure as ordinates, and durations of closure as abscissas. For convenience, the time abscissas have been marked off in intervals, instead of seconds. The curves, it will be noted, become very steep as the duration of closure becomes short, and, in the limit, appear

FIG. 4—MAXIMUM RISE OF PRESSURE AT THE GATE FOR VARIOUS HEADS

*The writer was unable to obtain an English translation of Mr. Allievi's paper, but his formula is commonly given as follows:—

$$h = NH/2+H(N^2/4+N)^{1/2}$$

where h = rise of pressure, in feet, above normal;
H = normal net head, in feet;
$N = (LV/gTH)^2$;
L = length of penstock, in feet;
V = velocity of water in penstock, in feet per second;
T = duration of gate closure, in seconds;
g = acceleration due to gravity, in feet per second per second.

†"Transactions," Am. Soc. C.E., Vol. LXXIX, pp. 238, 242. Mr. Warren's formula is $h = (LV/g)(T-L/a)$, where a = velocity of the pressure wave, and the other symbols have the same significance as in this paper.

‡"Transactions," Am. Soc. C.E., Vol. LXXIX., pp. 289-299; and Vol. LXXXII., p. 185. Mr. Vensano's formula is: $h = 2LV/gT$ with the limitation that h can never be greater than Va/g.

§"Transactions," Am. Soc. C.E., Vol. LXXIX., pp. 277-281. Mr. Johnson's formula is:

$$H_{max.} = (2MV/N^2)[M+(M^2+N^2)^{1/2}]$$

where H_{max} $M = LV$ = maximum rise of pressure, in feet, above normal; and $N = 2gVT$, in which V is the normal net head in feet, and the other symbols have the same significance as in this paper.

¶"Water Hammer in Hydraulic Pipe Lines," by A. H. Gibson. Mr. Gibson's formula is (in order to prevent confusion with the foregoing, some changes have been made in the nomenclature):

$$p' = (w/g)\{[(L/A)(A_1/T)]^2+(L/A)(A_1/T)[2gH+(LA_1/AT)^2]^{1/2}\}$$

where p' = rise in pressure, in pounds per square foot, behind the valve at the instant where closure is complete, and therefore when p is maximum;
A = cross-sectional area of penstock, in square feet;
A_1 = maximum effective area of valve opening, in square feet;
w = weight of a cubic foot of water;
and the other symbols have the same significance as in this paper.

‖"Transactions," Am. Soc. Mech. Engrs., Paper No. 1354. Mr. Uhl's formula is:

$$DH/H = \tfrac{1}{2}n[n+(n^2+4)^{1/2}]$$

where DH = rise of pressure, in feet, above normal;
$n = LV/gTH$, in which the symbols have the same significance as in this paper.

**"Transactions," Am. Soc. C.E., Vol. LXXIX., pp. 277-281. Mr. Johnson's formulas, to be solved as indicated in his discussion, are:

$$t = T[(x-1)^{1/n}/x^{1/n}]$$

where $x = R\{[H+(y_0)^{1/2}]/[J-(y_0)^{1/2}]\}$,
R being $[J-(Y)^{1/2}]/[H+(Y)^{1/2}]$,
and $n = [(2gT)^2/LV)^2+1]^{1/2}$
$H = [LV/2gT(Y)^{1/2}](n-1)$
$J = [LV/2gT(Y)^{1/2}](n+1)$

***"Water Hammer in Hydraulic Pipe Lines," by A. H. Gibson.

to approach infinity as the duration of closure approaches zero. For low heads Joukovsky's limit of maximum water-hammer is passed by these curves at points of relatively long duration of gate closure. In Fig. 3, a similar series of curves for various heads has been plotted from the result obtained by using the writer's formulas, and these are shown in full lines. It will be noted that these curves show maximum water-hammer for any duration of closure from zero up to one interval $2L/a$, and, as the duration of closure becomes longer, the resulting rise of pressure finally approaches, within certain limits, the value shown by the Allievi curve. For low heads and short durations of closure, the Allievi curves generally show higher values of pressure rise than the writer's; but, for high heads and short durations of closure, they show lower values of pressure rise. This interesting fact will be referred to later when discussing the pressure-time curves.

The formulas of Messrs. Warren and Vensano do not include the net head as a factor, and, therfore, each may be represented, as shown in Fig. 3, by a single curve for all heads. Although these two formulas are objectionable, because they neglect the influence of the net head, it is evident, from the position of the curves representing them in Fig. 3, that under certain special conditions they will give, at least approximately, correct results. These conditions will be referred to later when discussing the pressure-time curves, but it is interesting to note here that Mr. Warren's formula gives approximately the correct results when the net head is such that the excess pressure will be a minimum for any

given duration of closure. Mr. Vensano's formula gives approximately the correct result when the net head is very high with respect to the velocity destroyed.

Fig. 4 has been drawn to show the manner in which the rise of pressure varies with the net head. The results shown by the curves in Fig. 3 are plotted for a given duration of closure, ordinates representing excess pressure, but abscissas representing net head (H_0). It is thus seen that, for a given duration of closure, the excess pressure becomes less as the head increases, until at a certain value of H_0 the minimum rise of pressure is reached, and, as H_0 continues to increase, the rise of pressure also increases until it reaches a final value, when H_0 is infinite. In the example shown in Fig. 4, L is only 820 ft., and this length would represent the limit of gravity head. The curves, however, have been extended for higher heads, on the assumption, of course, that the head is produced by applied pressure. The corresponding curves obtained from the results of the Allievi, Warren, and Vensano formulas are also clearly shown in Fig. 4.

Pressure-Time Curves

The pressure-time curves, Figs. 5, 6, and 7, show clearly the changes in pressure that take place during the closure

of the gates under various typical conditions. The corresponding curves obtained from the formulas of Allievi, Warren, and Vensano have been shown in these figures for the purpose of comparison with those of the writer, and in order that the various results may be studied and explained. In some cases velocity-time curves have also been drawn, in order to show the variable rate of retardation caused by uniform gate closure.

It will be noted first that R. D. Johnson's pressure-time curve, based on Allievi's formula, or indeed Allievi's formula itself, gives the maximum pressure rise always at the end of the closing time. Mr. Warren's curve shows the excess pressure rising uniformly to a maximum at the end of the first interval and then remaining constant until the end of the closing time. Mr. Vensano's curve shows the excess pressure rising uniformly to a maximum at the end of the first interval, falling uniformly to zero at the end of the second interval, and repeating this vibration until the end of the closing time. The writer's pressure-time curves may be similar to any one of these three, depending on the duration of closure and the net head acting on the orifice, or on both of these factors.

Commencing with Fig. 5, it is seen that the pressure-time curve, under the conditions stated, is almost identical with that given by R. D. Johnson, as far as can be detected by the eye. A careful consideration of the writer's formula, however, will reveal the fact that the pressure-time curve obtained from it is not continuous, but is made up of a series of curves, each being one interval long, and cusps or changes of curvature occur at the end of each interval. Under other conditions, the cusps are plainly visible, as, for example, in Figs. 6 and 7. For any finite conditions, these cusps, theoretically, do not disappear, that is to say, the tangent at the end of one interval never exactly equals the tangent at the beginning of the next interval. Furthermore, the slope at the beginning of the writer's curve is never exactly the same as the slope of the Johnson curve. For all practical purposes, however, the pressure-time curves shown in Fig. 5 (and numerous other curves for similar conditions) are almost identical, and the maximum pressure rise occurs in both of them at the end of the stroke. This is interesting because the two theories from which the respective formulas are derived are totally different. When the conditions are such as to produce practically identical pressure-time curves similar to the foregoing, it indicates that the effect of the compressibility of water, the elasticity of the pipe walls, and the resulting harmonic vibrations in the water column may be neglected, and in such cases the assumptions, on which the Allievi formula has been based, are practically sufficient.

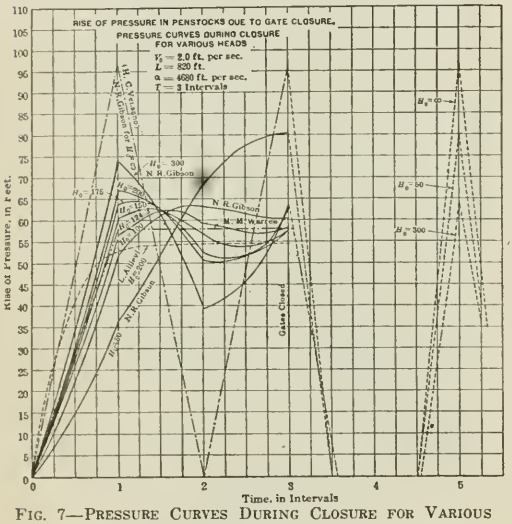

FIG. 7—PRESSURE CURVES DURING CLOSURE FOR VARIOUS HEADS

The results obtained from the Warren and Vensano curves are much at variance with the foregoing, as indicated in Fig. 5, and the writer is of the opinion that neither of these formulas can apply for all values of H_0, and, only under certain conditions, which will be mentioned later, are they approximately correct.

As shown in Fig. 3, the maximum pressure rise given by the writer's formulas, as would be expected, is nearly always less than that given by the Allievi formula when the duration of closure is short and when H_0/V, the ratio of head to velocity destroyed, is small. When the ratio of head to velocity destroyed is large, the reverse is the case, and, when H_0 becomes infinitely large, the writer's formulas agree with that of Mr. Vensano and give results twice as great as Allievi's formula for any finite duration of closure greater than one interval. Even when the values of maximum pressure-rise, as given by the Allievi formula, are in close agreement with those of the writer, both for short and long durations of closure, the respective shapes of the pressure-time curves may be different. Figs. 6 and 7 show clearly the characteristics of the pressure-time curves in a number of typical cases, and a close study of them, together with Fig. 4, will make clear the relation that exists between the rise of pressure and the net head for any velocity destroyed. The shapes of the pressure waves that continue after the gates have been closed, until damped out by friction, are also indicated in Figs. 2 and 7. (See last week's issue for Fig. 2).

Referring now to Fig. 7, it will be noted that the particular case when Mr. Warren's formula gives approximately correct results is when the head is such that the rise of pressure due to gate closure is a minimum for the particular velocity destroyed. This occurs when $H = (3/7)(aV/g)$.

FIG. 8—FROM VENSANO'S FORMULA

Fig. 7 shows, also, the shapes of the pressure-time curves for various heads, and indicates the variation in time when the maximum pressure occurs during closure.

The foregoing examples, except Tables 2 and 5, have all been calculated for uniform gate motion. As the writer's formulas may be applied for any variable rate of gate motion, it is interesting to determine the nature of the gate motion for various heads that would be required to produce diagrams similar to those proposed by Messrs. Warren and Vensano. A diagram of the shape proposed by Mr. Warren may be produced by the simple expedient of increasing the speed of gate travel at the end of the first interval to double the rate of its motion during the first interval and maintaining this double rate until the end of the stroke. Such an operation, though giving the same shape to the pressure-time diagram, will not, of course, give the same rise of pressure as for the same duration of uniform closure, but the latter is given by a gate motion similar to that shown in Fig. 9. If a pressure-time diagram of the same shape as

Time, in Intervals

FIG. 9—FROM WARREN'S FORMULA

Mr. Vensano's is desired for a low head, a very complicated gate motion would be required, such, for example, as that shown in Fig. 8. In a similar manner, the gate motion required to produce any suggested form of pressure-time curve may be determined.

The manner in which excess pressures vary from gate to origin has been explained in Miss Simin's translation of Professor Joukovsky's paper, although therein worked out on the erroneous assumption of uniform retardation of the velocity of the water flowing in the pipe.

O. V. Kruse, who was associated with the writer at the time this paper was first written, has made an original study of the variation in excess pressure from gate to origin, based on the writer's application of Joukovsky's theory to slow-closing gates. The results of this study prove that when the duration of uniform closure is less than $2L/a$ the maximum pressure is exerted along the pipe to a point where the distance to the origin is equal to $Ta/2$. From that point to the origin the pressure reduces uniformly to zero. When the duration of uniform closure is equal to, or greater than, $2L/c$, the maximum rise of pressure occurs at the gate, and from there to the forebay or origin reduces to zero, uniformly along the length of the pipe.

Fall in Pressure

Professor Joukovsky's theory of pressure waves applies also to the fall in pressure produced by opening a valve or gate at the end of a pipe line, and the application of his theory to the case when a valve is gradually opened may be made in a similar manner to the foregoing. It is obvious, of course, that the fall in pressure caused by opening a valve in a certain time is not precisely the same as the rise in pressure caused by closing the valve in the same time, because the rate of acceleration cannot be the same as the rate of retardation. It would lengthen this paper unduly, however, to do more than state here that the formulas for fall in pressure may be obtained in a similar manner to those given herein, the principles being the same in both cases.

Experimental Results

The writer has not yet had an opportunity of testing the formulas presented in this paper by experiments, to show, not only the correctness of the values of maximum pressure rise, but also the shapes of the pressure-time curves under various conditions. It is expected, however, that an opportunity of doing so may possibly occur in the not too distant future. In the meantime this paper is presented in the hope that it will receive criticism or confirmation from those interested in the subject.

The experimental results obtained by Mr. Vensano, and presented in his paper entitled "Pulsations in Pipe Lines," give some striking confirmation of the correctness of the writer's formulas, not only as regards the maximum pressure rise, but also as indicating the resemblance between the calculated and observed pressure-time curves, both before and after the gate was completely closed, and at various points along the pipe line, as well as at the gate.* These, however, were carried out under a very high head (1,260 ft.), and could hardly be accepted as a general proof.

The writer also proposes to show how the pressure-time diagram may be used to determine the velocity of flow in a pipe, for the purpose of measuring the rate of discharge previous to the closing of the gate. This will be made the subject of another paper to be written at a future time.

In conclusion, the writer desires to accord credit to O. V. Kruse for the valuable help he has given in the preparation of this paper, to R. L. Hearn for the work of preparing Figs. 8 and 9, and to R. D. Johnson for the many helpful suggestions he has kindly made.

*See discussion by Norman R. Gibson in *Transactions*, Am. Soc. C. E., Vol. LXXXII., p. 236.

Jeffrey Mfg. Co., of Montreal, P.Q., and Columbus, Ohio, have opened a new branch office in Detroit, Mich., in charge of O. B. Westcott, who for many years past has been in the company's sales, engineering and construction departments.

RENSSELAER VALVE CO. APPOINTS AGENTS

ANNOUNCEMENT has been made by Irving A. Rowe, general manager of the Rensselaer Valve Co., Troy, N.Y., that he has appointed the General Supply Co. of Canada, Ltd., as sole representative for the Dominion of Canada with the exception of the city of Winnipeg and the province of British Columbia. For these two territories Mr. Rowe is under contract with other representatives.

The General Supply Co. has been rapidly building up a very strong water works department. Following are some of the firms it is now representing:—

Wallace & Tiernan Co., Inc., who are manufacturing an apparatus for controlling chlorine gas for treating water and sewage.

Electro-Bleaching Gas Co., who manufacture liquid chlorine.

Pitometer Co., makers of all types of instruments, recording and otherwise, operating on the pitot principle. This firm also makes complete water works surveys for detecting any leaks or excessive use of water on city supplies.

Pittsburgh Filter & Engineering Co., manufacturers of all types of filters and controlling apparatus.

Builders' Iron Foundry, who manufacture venturi tubes and recording devices, and special equipment for controlling and recording flows of any nature.

National Water Main Cleaning Co., who have perfected a mechanical apparatus for removing all deposits and encrustations of any nature from the interior surface of pipe lines.

The head office of the General Supply Co. is located at Ottawa, with G. B. Greene as general manager. The company has branches in Montreal, Toronto, Winnipeg and Vancouver. Among the technical staff in its water works department are J. Van Benschoten, formerly engineer with the Wallace & Tiernan Co.; R. L. Haycock, formerly water works engineer of Ottawa and superintendent of transportation with the Algoma Steel Corporation, Sault Ste. Marie; A. G. Wilkins, an engineering graduate of McGill University; and C. Laurendeau, an engineering graduate of Laval University, Montreal.

The Rensselaer Valve Co. manufactures gate valves for all pressures and types of operation and control, check valves, bronze valves, valve indicators, indicator posts, floor stands, valve boxes, air valves and Corey-type fire hydrants. The Rensselaer factory is in Cohoes, near Troy, N.Y., with sales branches in New York, Pittsburgh, Chicago and Louisville. The firm was established in 1853.

New materials for use as concrete aggregates (such as iron-ore tailings, graphite tailings and garnet tailings) are being investigated by Sub-Committee No. 7 of the Committee on Concrete and Concrete Aggregates, American Society for Testing Materials. H. S. Mattimore is chairman of the Sub-Committee.

The Canadian Engineering Standards Association has formed committees dealing with wire rope, steel bridges and their construction, rails and track, electrical work and aircraft parts, with a view to obtaining an agreement of Canadian specifications or standards that will be acceptable to nearly all concerned. In this work consideration will first be given to existing specifications or standards that have proved satisfactory in this country, Great Britain or the United States.

Lord Kelvin, lecturing to his class in Glasgow University, getting his eye on a student whose thoughts were evidently far from the class-room, pounced on this man and asked, "Will you please tell me what electricity is?" The startled student stammered and replied, "Please, sir, I have forgotten." Kelvin then turned to his class and said, "Gentlemen, behold this sad spectacle. The only man that ever knew what electricity is, has forgotten."—From an address to the London Rotary Club delivered by E. V. Buchanan, general manager of the Public Utilities Commission, London, Ont.

ROAD DRAINAGE AND FOUNDATIONS*

By Geo. Hogarth
Chief Engineer, Ontario Department of Highways

IN building any roadway, whether for light or heavy traffic, two of the most important points to be considered are drainage and foundations.

The stability of the entire road surface depends upon the foundation and the strength and life of the foundation largely depends upon the facilities provided for drainage. While proper attention may be given to the drainage of the surface of the road by giving the roadway sufficient crown to shed the water, the great importance of subsurface drainage may be entirely overlooked. There are, therefore, surface and subsurface methods of drainage and the very great importance of each must be realized and used to the fullest extent if we desire a permanent foundation. A sound and enduring foundation cannot be secured on subsoil saturated with water, but a good foundation can be secured by the simple means of keeping the subsoil dry. If water is not excluded from the foundation it will sooner or later destroy the road surfacing, since no road ever built could escape destruction should the foundation become yielding and soft.

Earth Loses Sustaining Power

The ordinary clays and earths form a naturally strong foundation when dry, but where the ground is wet and springy a good road cannot be constructed without proper subdrainage since when wet the earth loses its sustaining power and the surface formation goes to pieces. Where the subsoil is gravelly, underdrains will usually not be required, but where it is sandy, give close attention to the damp or wet spots and provide ample subdrainage.

It may be said that the whole problem of improvement and maintenance of ordinary country roads is one of drainage. Upon earth roads drainage is especially important because the material of the road surface is very susceptible to the action of water and so, more readily destroyed than are the surfaces of the better class of roads. An undrained earth road offers a splendid opportunity to the frost, and a spring thaw may result in such a road being impassable for days or weeks. A road on a wet undrained bottom will always be troublesome and expensive to maintain, and it will be economical in the long run to go to considerable expense in making the drainage of the subsoil as perfect as possible.

There are three systems of drainage, namely: Underdrainage, side ditches and surface drainage, and the objects of each will be stated.

Underdrainage will lower the water level in the soil and keep it at a safe distance from the foundations. This aids the action of the sun and wind, which tend to dry the surface of the road, but if the foundation, due to lack of underdrainage, is soft and spongy, the road will soon become a mass of mud.

Underdrainage dries the ground quickly during the spring when otherwise a saturated condition of the soil would exist.

Underdrainage intercepts the subsurface flow of water beneath the crust of the road.

Reduce Heaving and Cracking

In many cases it will be noticed that though the ground is dry, when it freezes in the fall, it is very wet and soggy in the spring when the frost comes out. The reason for this condition is that after the ground freezes, water rises slowly in the soil and if it is not drawn off by underdrainage it saturates the subsoil and rises further as the frost goes out. Underdrainage not only removes the water but reduces and will in many cases prevent the destructive heaving effects of frost.

The heaving and cracking of pavements may be entirely attributed to the freezing of water in the subgrade under the pavement. Underdrainage will greatly lessen the damage done in this way by the frost, but entirely to prevent such destructive action may be very difficult. It may be said that when underdraining a section of road known to have a wet subgrade it is well to provide a liberal number of drains. Too many cannot be laid. Particular attention to the underdrainage should be given at points on the road from 50 to 200 feet or more down grade from the top of a hill or slope and particularly so if the roadway is in excavation. Water will usually filter out to the surface at such points and the entire skill of the roadbuilder will have to be exercised in locating subdrainage to prevent heaving and cracking. In all such cases do not curtail the underdrainage, but rather put in every foot of tile that can be placed.

Wherever underdrainage is provided be careful to provide proper grade and good outlet for the tile since poor results will come from tile that are indifferently laid and improperly vented.

Tile drains furnish the usual means for subdrainage, but in some cases a blind drain may be used to good advantage. The construction of a blind drain is accomplished by opening a trench several feet deep along or across the road and afterwards filling the trench with stone. The depth, distance apart and location of such trenches will depend entirely upon the conditions encountered and the result desired. Careful attention to the subdrainage of the road if of great importance and money spent for such work is always a splendid investment.

Side ditches for all country roads are essential. Their object is to receive the water from the surface of the travelled roadway and the grade of the ditch should be such that the water is carried rapidly to a good outlet. Such ditches also intercept and carry away water that would otherwise flow from the side hills upon the road. Side ditches need not be very deep; a depth of 2½ or 3½ feet below the crown of the roadways will usually be found sufficient and the sides should be given a slope flat enough to prevent caving. In order to be effective, ditches should have as great a grade as possible, they should be well cleaned out and have free outlet in some creek or stream.

Surface drainage of the traveled portion of the road affects mainly the maintenance of the road and is accomplished by giving the road or pavement surface a crown which tends to shed the water to the side ditches. The slope of the crown should be sufficient to carry the water freely and quickly to the side ditch. The proper crown to use will vary with the nature of the roadway; when a good surface is maintained, a moderate rise will be found sufficient. For earth, clay or gravel roads a usual crown is one inch per foot, while for bituminous or concrete pavements ½ or ¼ of an inch per foot is ample.

Foundations

While drainage is undoubtedly one of the first essentials of good highways, the foundation of a road is also of great importance and one of the first substantial advances in road building was made when the laying of a course of stone for the base of a road was adopted.

The foundation of a road should normally last a number of years while the cost of maintenance should be for replacing and renewing the worn out surface. Such conditions are difficult to obtain since the foundation of 4 inches of crushed stone to-day may be entirely inadequate to-morrow under more severe traffic. The heavy loads using highways to-day require an abundance of material in the foundation of the roads and if our work is to be enduring we must see to it that strong and sound foundations are provided.

Frequently the taxpayer may enquire as to why so much material is required in a road and a demand will be made for more surface with a smaller amount of stone hidden in the foundation. Such an enquiry loses weight when the same ratepayer states that a concrete road 6 inches thick is too heavy and his idea of a concrete road is a surface of concrete about an inch thick spread over the entire space between the fences.

Roads built only a few years ago are in many cases in poor condition or destroyed to-day because a shallow, weak foundation was provided. Improved roads naturally draw traffic and people will go many miles out of their way in order to travel over a section of good road. This fact should be

*Paper presented to the Canadian Good Roads Association.

given full consideration in designing a road and any traffic census made prior to reconstruction should be considerably increased in order to estimate the travel on the improved surface. A road is not rebuilt to provide only for present traffic but it is rebuilt to carry present traffic together with whatever vehicles may use it when improved and in some cases it may be found that the traffic on an improved road immediately after reconstruction is ten or more times the original number of vehicles using the road.

Soil Determines Foundation Depth

The strength of the foundation of a road is greatly affected by the supporting power of the different soils and in order to obtain a road surface having a uniform resistance, the thickness of the crust will need to be varied. A greater depth of foundation will be required on soft clay than on gravel and for soils of intermediate strength a varying thickness will be required. Soils of poor supporting power will carry safely a load of about 600 pounds per square foot while gravel subsoil is safe under a loading of about 3,000 pounds per square foot.

Many kinds of foundation courses are available in the construction of roads, such as crushed stone, screened gravel, pit gravel, field stone, quarry stone or Telford. Before placing a foundation course the subgrade should be properly rolled in order to solidify the surface and prevent the material of the foundation being forced into the soil. This point is as important with a gravel road as it is with more permanent types of construction. A smaller amount of crushed stone or gravel will be required to build the foundation of a road on a consolidated subgrade and the rolling and compacting of the subgrade before placing the foundation is therefore an economy. A compacted subgrade also enables the foundation of the road to better withstand the effects of heavy traffic, whereas a soft and yielding subgrade tends to cause a sinkage of the foundation with consequent hollows and holes in the road.

Crushed stone where used as a foundation for a macadam road should be not less than 6 inches in thickness when compacted and the size stone will usually be about that passing a 2½ inch ring.

Screened gravel of 1 inch to 3 inch size may be used in place of crushed stone and when placed in the road a filler containing some clay or loam should be spread in order to thoroughly consolidate the stones.

Such gravel does not interlock as crushed stone does and a thicker foundation course of gravel is therefore required.

Field Stone and Telford

Field stone used for a foundation may be laid in one course from 6 inches to 12 inches in depth and the inequalities between the stones filled with coarse gravel or crushed stone. The depth of the course should in all cases be suited to the average size of field stone available as it is not economical to break them to a definite size. A variation of an inch or so in the size of the stone is of no consequence since the surface stone will serve to even up all inequalities.

The Telford base may be composed of quarry stone which has been broken to size with a stone hammer. Such foundations have given good satisfaction when used but the cost of hand placing the stones seems to have outweighed the advantages of this type of construction.

In conclusion it may be said that the adequate drainage of a road is the first requisite to permanence and if we add to proper drainage a sound foundation, the cost of maintaining the surface of the road will be greatly lessened. Drainage and foundations are two very essential details of road construction and close attention to these points when designing and constructing a road will lead to better, more durable and more satisfactory roads.

The Minister of Labor has created a Board of Conciliation to deal with the dispute between the Bedford Construction Co. of St. John, N.B., and its employees engaged on the Courtney Bay construction work. Sir Ezekiel McLeod will act as chairman, and Brig.-Gen. C. L. Hervey, of Montreal, will represent the company, and J. E. Tighe the employees.

COST-PLUS-FIXED-FEE CONTRACT

Building Construction a Huge Gamble Except Under This Form of Agreement—Co-operation for a Better Building, Plus Greater Speed and Security

By A. E. Wells
President, Wells Bros. Construction Co.

IF a half dozen street urchins are caught by a burly representative of the law while engaged in the pastime of shooting craps, the law against gambling acts. Lawmakers have recognized that gambling is an unnecessary evil and have, so far as possible, put a stop to it. Yet an owner and a contractor can gamble with a million times the stake of the street urchins without fear of the law, and it is done constantly under the guise of the lump-sum contract.

Under its terms the contractor agrees that for a certain sum of money he will guarantee the owner against all the unknown conditions involved in putting up a structure. Whether he makes his figured profit or whether he loses so heavily as to be put out of business rests partly on his ability to figure costs, but largely on his luck in failing to meet those conditions which would increase costs.

Both parties to this contract stand to gain or lose. If the job costs 20% more than estimated, the owner gains to the other's loss. If conditions make considerable saving possible, then the contractor gains to the owner's loss.

Should Contractor Guarantee Cost?

Many contractors who in times past have built extensively in your field are no longer operating. Others have taken their place. Perhaps the majority of the missing firms are those who were expected not only to build according to specifications and within the time limit, but to gamble that their costs would fall within a fixed contract price. Gambling against variables such as the forces of nature and the conditions of labor—they lost. In many cases their failure involved an added investment on the part of the owner or possibly the surety company. No one gained.

The contractor is an expert retained to assemble certain materials into a finished structure. The question being asked to-day is, "Should the contractor insure the owner that his structure will not exceed a definite contract price?"

In competitive bidding the cost of this insurance is paid generally by the low bidder out of profits or, as frequently happens, out of his capital, for the reason that he is more likely to get the contract as he scales down his allowance for contingencies. In fact the man whose bid includes a safe allowance for insurance against higher costs cannot expect to obtain work under the competitive bidding system. The inevitable result is the bankruptcy of many contractors and an additional cost to the owner or the surety company to complete the unfinished contract. This situation has come to such a point that surety companies are refusing to write surety bonds on fixed-price contracts except under specially favorable conditions, and frequently recommend to owners the cost-plus-a-fixed-fee contract.

Reliable Estimate More Valuable

But from the owner's standpoint is it not preferable to know in advance what a certain project will cost? It is true that a careful estimate is due him. It should be made by a reliable contractor and checked by owner's architect and engineer. Such a figure should be more satisfactory than a competitive bid which does not necessarily show the cost of the building but only what some contractor is willing to gamble is the cost of the job.

An issue of bonds for an office building or other structure can as well be based upon a careful preliminary estimate in either case. It can only run below the estimate under the cost-plus-fixed-fee plan. Is not the owner entitled to the possible saving?

Additional financing may be an unfortunate necessity, but is there reason why the contractor should be asked to under-write the accident of greater cost?

At the Chicago meeting of the Associated General Contractors of America, this topic was discussed and Brig.-Gen. R. C. Marshall, Jr., chief of the construction division of the U.S. War Department, pointed out the fault of the usual pre-war basis of contract. He showed the impossibility on recent war work of asking for competitive bids, because speed was the essence and detailed plans and specifications were never complete at the time when construction had to start.

On such work it was, therefore, out of the question for a contractor to bid on a flat contract price basis. It would not have been fair to either side. As a result, there was developed a form of contract known as the cost-plus-sliding-scale-fee contract.

Gen. Marshall said that early in the spring of 1918, the program of work before the construction division was so extensive that it seemed advisable to have the merits of this form of contract again passed upon, and a committee of eminent business men unqualifiedly endorsed this form of contract. In Gen. Marshall's own words at the convention of general contractors:—

"Unjust, Inequitable and Uneconomic"

"No contractor should be called upon nor permitted to undertake the performance of any contract that within the four corners of the paper upon which it appears is, or may be, written the financial bankruptcy of the contractor. It is unjust, it is inequitable, it is uneconomic. The great lesson of this war on the subject of the relationship between the contractor and the owner is the cost-plus contract. This represents the only equitable basis under which a contractor may perform constructive and economic services for the owner. It is the only form of contract which affords protection to both parties. To me all the energies, the thought and the experience of this country within its own continental lines during the past year and one-half of this world struggle, shall have been in vain unless out of it shall grow, as a permanent institution, solidifying the economic relationship between the contractor and the owner, the cost-plus contract."

We have been operating under this plan almost exclusively for several years. We know that it is possible to convince most business men of the perfect fairness of the cost-plus contract, and among our clients are several who would be the last to tie themselves up with us on any basis of contract likely to be unfair or dangerous. We have built on this basis for the Robert Simpson Co., Ltd., Toronto, five separate buildings; for the William Davies Co., Ltd., Toronto, six buildings; and for Montgomery, Ward & Co., four successive times.

For these firms we have been able to start actual construction much earlier than otherwise would have been possible, which means early occupancy. The reason for this is that we can start the foundations just as quickly as the foundation plans are complete, and further design and construction may go on coincidently.

Complete Plans Not Necessary

Money tied up during construction earns nothing until the building is ready for occupancy, and the interest often amounts to a considerable sum. When we have opportunity to work with the owner, engineer and architect from the very inception of the plans, and when we begin foundations as soon as the general contour of the building and equipment are determined upon, we are able materially to cut down the period during which the owner's capital is unproductive. Under the lump-sum contract it is necessary that the plans be complete before bids are taken, which may delay occupancy for months, and without occupancy a building investment is poor as a dividend producer.

But, while speed is of first importance in most building contracts, yet fairness to both parties is an equally good reason for the general adoption of the cost-plus contract, and on that basis our company is now operating almost exclusively.

Unquestionably the contractor is called in because he is an expert in building, and not to absorb the risk entailed in the lump-sum contract. If it is not the purpose of the owner to buy price insurance along with his building, then cost-plus-fixed-fee is a better basis.

BRITISH ENGINEERING STANDARDS REPORTS

(Concluded from page 294)

Report No. 71-1917. *Report on British Standard Dimensions of Wheel Rims and Tire Bands for Solid Rubber Tires for Automobiles.*—This report gives standard sizes of wheel rims and corresponding internal dimensions of solid rubber tires, for sizes of wheel varying from 670 mm. to 881 mm. Metric dimensions are used throughout.

Report No. 72-1917. Revised September, 1917. *British Standard Rules for Electrical Machinery* (excluding motors for traction purposes).—This important report is intended to define the conditions which characterize British standard electrical machinery, including transformers but excluding traction motors, and to provide the purchaser and manufacturer with a general specification indicating the information which should be forwarded with an enquiry or an order for an electrical machine. Methods of defining the rating or rated output are formulated, and in this connection are in substantial agreement with the corresponding rules of the American Institute of Electrical Engineers. Enquiries based on these rules will enable the purchaser to compare tenders received from various manufacturers.

Report No. 74-1917. Revised September, 1917. *British Standard Specification for Charging Plug and Socket for Vehicles Propelled by Electric Secondary Batteries.*—This report contains the provisions necessary to secure interchangeability between any charging plug and any socket of the concentric type. Dimensions of the contact portion of the plug and socket, and dimensions of the gauges needed to check these are given.

Report No. 75-1916. *British Standard Specifications for Wrought Steel for Automobiles.*—This important report contains definitions of terms used, methods of testing, and specifications for ten grades of carbon, nickel and nickel-chrome steel, each specification giving chemical composition, tensile and brinell tests.

Report No. 76-1916. *British Standard Nomenclature of Tars, Pitches, Bitumens and Asphalts Used for Road Purposes and British Standard Specification for Tar and Pitch for Road Purposes.*—This valuable report defines tars, pitches, bitumens, and asphalts for road purposes, distinguishing between the tar products and bitumens and asphalts. In this respect the practice of the B.E.S.A. is not in accordance with that usual in the United States, where the term bituminous is applied in a wider sense than in Great Britain. The specification gives definitions, properties and methods of testing for two qualities of tar, and for pitch suitable for pitch-grouting.

Report No. 82-1919. *British Standard Specification for Starters for Electric Motors* (face-plate type).—This report covers definitions, pressures, methods of enclosure, standard sizes and ratings, general construction, marking and tests

Report No. 84-1918. *Report on British Standard Fine (B.S.F.) Screw Threads and Their Tolerances.*—This report gives revised tables of dimensions for British standard fine screw threads and covers theoretical dimensions and standard sizes and tolerances of bolts and nuts for two grades of fit. The report also contains an appendix dealing with methods of determining and compensating for errors in pitch, form of thread and diameter. Much information is given regarding methods of gauging screw threads.

Report No. 88-1919. *British Standard Specification for Electric Cut-Outs for Low Pressure, Type O.*—This specification covers dimensions and standard sizes of cut-outs for low pressure and ordinary duty. A separate specification is contemplated for heavy-duty cut-outs.

Report No. CL3,750. *Interim Memorandum on French Metric Screw Threads for Aircraft Purposes.*—This memorandum describes the system of screw threads for aircraft purposes used by the French military authorities, and is accompanied by tables showing limits of size, tolerances, etc., for two grades of fit. The form of thread is that of the Systeme Internationale, in which the crest is cylindrical while the root of the thread is curved in section. The finer tolerances are provided for cases where great accuracy is required. The second grade tolerances are suitable for ordinary bolts and nuts.

ESTABLISH AN "INTERESTING CORNER"

ONE of Cleveland's leading financial institutions, the Cleveland Trust Co., whose building is at a very prominent corner in the business section of that city, has offered the use of a space adjoining its head-office building, for exhibitions of machinery and other products of Cleveland factories. The idea conceived by the Cleveland Trust Co. will prove of interest to many other municipalities where exhibitions of products manufactured locally will be of educative value and will also arouse civic pride and add to local knowledge of civic affairs. The more that citizens know of the products that are manufactured within their own town, the more likely are they to be boosters for their own municipality and to realize better its advantages for themselves and their children.

The corner which the Cleveland Trust Co. devotes to these exhibits is semi-circular, slightly above the sidewalk level, and enclosed with a low but heavy ornamental metal arilink. Each firm is allowed to continue its exhibit for a week, and there is no charge for the space. Exhibits are booked in the order in which applications for the space are made to the trust company.

The public has taken so keen an interest in these demonstrations that the spot has been popularly named "Cleveland's Most Interesting Corner." At this corner the public can obtain a close view of the operations and processes entering into the manufacture of all their home products. The exhibitions are much like those interesting ones in the Process Building at the Canadian National Exhibition, which annually proves one of the strongest attractions of that great show.

The Canadian Manufacturers' Association is spending large sums of money in advertising to the Canadian people that they should buy Canadian-made goods and so reduce our adverse trade balance. To assist this advertising campaign, one of these interesting corners should be established in every city throughout the Dominion. They would show the people, by practical demonstrations, the care and accuracy with which Canadian products are prepared, and the quality of the materials used in their manufacture. Not only would these exhibits be of benefit in increasing the sales of Canadian goods, but they would also add greatly to the knowledge possessed by Canadians of Canada's resources and manufactures.

CLASSIFICATION OF E.I.C. MEMBERS

AT present the Engineering Institute of Canada is composed of honorary members, members, associate members, juniors, students and associates. The council of the Institute might advantageously consider an amendment to the constitution and by-laws, changing the title of "member" to "fellow," and of "associate member" to "member." Should the vote favor such an amendment, the Institute would then consist of honorary members, fellows, members, juniors, students and associates.

The advantages of these changes in titles are several. One of the most important is the abolition of the misleading and inaccurate title, "associate member." The general public, and all excepting those thoroughly conversant with the Institute's affairs, are likely to think that an associate member is one who is merely associated with the Institute, and who is not an active member. As is well known within the profession, an associate member is just as much a corporate member of the Institute as is a member, but a layman is not likely to grasp the full significance of the classification, and as a result the associate members are unquestionably suffering in professional status.

We believe that the classification of "fellow" would be popular among the present "members." The word "fellow" in all scientific societies is a mark of distinction and eminence. The public are familiar with the term and are accustomed to respect it. They know that in connection with many other societies, fellowship is the highest grade of membership obtainable. There is something about the title that resembles a technical degree. A "Fellow of the Engineering Institute" would more readily obtain public respect than a "Member of the Engineering Institute." The public has always associated "fellow" with distinguished and learned men, excepting when used as a slang term. The title, "member," is so common in connection with so many different societies of a general nature for which the only entrance qualification is an annual fee, that it carries no distinction whatever. Many laymen do not realize the vast difference between being a member of a Board of Trade, for example, and being a member of the Engineering Institute of Canada. But church, political and other societies include no fellowships; the term, "fellow," is reserved by almost universal consent for learned members of respected scientific and professional societies.

There are many associate members of the Institute who could readily qualify as members but who have never applied for the transfer because the annual fees for members are heavier than for associate members. The attraction of the title, "fellow," would undoubtedly induce scores of these men to apply for transfer, and in this way the funds of the Institute could be considerably augmented in an entirely legitimate manner.

If the rather long abbreviation "A.M.E.I.C." could be abolished, there would be more uniformity in the abbreviations indicating the different degrees of membership within the Institute. F.E.I.C., M.E.I.C., J.E.I.C., S.E.I.C., and A.E.I.C. would be readily recognized as the abbreviations respectively for fellow, member, junior, student and associate.

Another advantage would be the avoidance of confusion in regard to "associate members" and "associates," another point of difference which the public does not grasp and concerning which apparently the members of the Institute themselves are often careless. Return post cards have often been mailed to members of the Engineering Institute, on

which the members were supposed to write their name and the rank held in the Institute, the cards being required for branch purposes or other official work. Many associate members merely write the word "associate" after their name. On the other hand, we have knows instances where one's statement that he was an associate of the Institute was understood to mean that the speaker was an associate member, although no such meaning was intended or implied. There is a wide distinction between the requirements for membership in the two classes, but there is entirely insufficient distinction between the two titles, in all fairness to the associate members.

The classifications above suggested, including fellows and members, but containing no associate members, is the classification that was adopted some time ago by the American Institute of Electrical Engineers, and which apparently is giving excellent satisfaction among the members of that very strong organization.

The necessary amendment to the constitution and by-laws is so simple that it would not cause any confusion. It would merely be necessary to substitute the word "fellow" wherever the word "member" now appears, and the word "member" wherever the words "associate member" now appear.

PERSONALS

SIDNEY APPLETON has entered private practice in Toronto in partnership with Willard Chipman, the firm to be known as Appleton & Chipman, with offices at 58 Wellington St. East. Mr. Appleton was born January 10th, 1883, in London, Eng., and is a graduate of the East London Technical College, subsequently spending two years in an engineering course at London University. Prior to his technical education, he spent three years as an apprentice machinist, fitter and erector, and one year as a switch board operator at the Ilford Municipal Electric plant. After three years at sea as a marine engineer, Mr. Appleton was engaged for six years with R. & H. Green & Silley Weir, Ltd., as chief draftsman and manager of the Royal Albert Dock Works, London, in full charge of ship repairs. He resigned that position to become chief engineer of Trinidad Oil Fields, Ltd., in the British West Indies, where he was in charge of railway, jetty and building construction, pipe lines, power plant and all field engineering work. After one year in Trinidad, Mr. Appleton came to Canada and became town engineer of Camrose, Alta., which position he occupied for two years, resigning to become shop superintendent of the Dominion Cartridge Co., who were then engaged on war contracts, and with whom he spent two years. In June, 1917, he left the Dominion Cartridge Co. to became assistant chief engineer of the marine engine department of the Imperial Munitions Board, Ottawa, where he was in charge of the drawing office in which designs were made for use by the various shipbuilders. He requisitioned all the necessary material for the construction of the ships, and was in charge of the production of same, having under him for that purpose a large staff of executives, engineers and clerks. Mr. Appleton is an asociate member of the Institution of Mechanical Engineers of Great Britain.

J. N. FINLAYSON, professor of civil engineering, Dalhousie University, has been appointed professor of civil engineering at the University of Manitoba.

A. B. CLARSON has resigned as general secretary of the Association of Canadian Building and Construction Industries. Mr. Clarson was formerly city engineer of Verdun, P.Q. J. C. Reilly has been appointed as acting secretary, with temporary quarters at 65 Victoria St., Montreal.

W. H. TAYLOR, who has been on the staff of Frank Barber, consulting engineer, Toronto, for the past twelve years, has resigned in order to undertake water works and sewer contracting on his own account.

MAJOR N. M. HALL has been appointed lecturer in civil engineering at the University of Manitoba. Major Hall graduated in 1907 at McGill University. Until he enlisted in the Royal Engineers in 1915, he was engaged with the Western Canada Power Co. and with Ducane, Dutcher & Co., consulting engineers, Vancouver.

J. PENROSE ANGLIN, of Montreal, president of the Association of Canadian Building and Construction Industries, has just perfected the merger of the Anglin and Norcross companies, which was announced some time ago, and last week made a public issue of preferred stock in the new concern, Anglin-Norcross, Ltd. Mr. Anglin has been elected president of the merged companies.

L. P. BURNS, who recently purchased all the outstanding interests in the firm of Burns & Roberts, Ltd., Toronto, announces a change in the firm name. This company will be known in the future as L. P. Burns, Ltd., the head office address remaining the same, namely, 301 Bank of Hamilton Building, with warehouse and shops at Ritchie Ave., Toronto. The firm is manufacturing and repairing steel plate work of all kinds, and light structural work. They are also acting as agents for the Chapman Valve Mfg. Co., Pittsburgh Piping & Equipment Co., American Cement Machine Co. and the Northwest Expanded Metal Co.

The fifth general professional meeting of the Engineering Institute of Canada is being held this week in St. John, N.B.

Montreal's building permits were valued at $1,541,245 for the month of August, an increase of $482,981 as compared with August, 1918. For the eight months of this year the total was $5,913,668, a gain of $2,205,790 as compared with the same period of last year.

A. E. Doucet, director of public works of the city of Montreal, states that 33½ miles of roadways have been given one coat of bituminous oil this season, and it is his intention to apply a second coat this month. This is the first time that Montreal has used road oil instead of water as a dust preventive on macadam roads.

Frederick Law Olmstead, of Boston, Mass., will address the town planning meeting at Ottawa, October 17th and 18th, on "The Fundamental Principle of City Planning." This meeting will be jointly held by the Canadian and United States town planning institutes, and many prominent town planners and architects from the United States will likely be in attendance.

A. W. Campbell, Dominion Highways Commissioner, addressed the Union of Nova Scotia Municipalities August 27th at Yarmouth, N.S., on "Federal Assistance in Road Improvement." Among the other speakers were W. G. Clarke, chairman of the Nova Scotia Highways Board, and J. W. Roland, the board's chief engineer, both of whom discussed the work of the board in its relation to the roads of the province.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

TENDERS PENDING

BRIDGES, ROADS AND STREETS

Amherstburg, Ont.—County Council will construct bridges over the Faucher drain, the Botsford bridge at Rose Hill cemetery and on the 7th concession of Malden. W. H. Knister, superintendent of good roads.

Amherstburg, Ont.—Imperial Bank is preparing plans for a bank and office building. C. A. Cuddy, manager.

Belleville, Ont.—City council intends to construct an asphaltic concrete pavement on part of West Bridge St., estimated to cost $11,665, and a Portland cement sidewalk on the west side of Ann St., from Bridge St. to Dundas, estimated to cost $1,582.68. City clerk, J. Wilfred Holmes.

Brockville, Ont.—Preliminary construction work has commenced on grubing and draining the provincial highway, from Brockville to Gananoque. Culverts, ditches and underdrainage will be commenced soon. The final surfacing of this road will not be completed until next season. Engineer Baldwin, Gananoque.

Caughnawaga, Que.—Tenders addressed to Duncan C. Scott, Deputy Superintendent-General of Indian Affairs, Department of Indian Affairs, Ottawa, and endorsed on the envelope, "Tenders for Road Work, Caughnawaga Indian Reserve, Que.", will be received up to noon, September 19th, 1919. Plans and specifications may be seen at the office of the Indian agent at St. Constant, and at the post-office at Caughnawaga, and may also be examined at the department in Ottawa.

Chatham, Ont.—Board of works contemplate construction of pavement on Queen St. South. H. A. Hammond, mayor.

East Oxford, Ont.—Tenders will be received by F. G. Jackson, clerk, East Oxford, Oxford Centre P.O., Ont., until noon, September 15th, for the construction of the Tuttle drain.

Fort William, Ont.—The federal government will improve trunk roads and the highway through the Thunder Bay district and the road from Nipigon to Fort William this season. Estimated cost of roads and bridges, $115,000. C. W. Jarvis, M.L.A.

Galt, Ont.—City council passed by-law for the construction of a pavement with curb and gutter on part of Wellington St. City engineer, W. H. Fairchild.

Hawkesbury, Ont.—Tenders will be received until 8 p.m., September 15th, by town council for construction of permanent roads, both of bituminous and macadam on Main, McGill and Regent St. Engineer, V. E. A. Belanger, L'Orignal. Town clerk, Eug. Paquette.

Kingston, Ont.—City council will construct sidewalks on Stephen St., North St., and Mack St. Ald. Graham, chairman, board of works.

Kingston, Ont.—The Kingston Suburban Road Commission, who received tenders last Monday for seven miles of water-bound macadam highway, are contemplating the award of further mileage, as the commission has a total of about forty-four miles of road to be built, some 16 ft. and some 9 ft. in width. It is the intention of the commission to surface this macadam with bituminous or other material at a later date.

Leamington, Ont.—Tenders for the dredge cutting and embankment, reinforced concrete and other works, and furnishing and installing a new submerged centrifugal pump in the repair and improvement of the Big Marsh drainage system in the Township of Pelee Island, Ont., will be received by Alex. Baird, C.E., Leamington, up to 12 o'clock noon, Thursday, September 18th, 1919. Plans and specifications may be seen at the office of the engineer.

Minitonas, Man.—Tenders will be received until noon September 15th, by the council of the rural municipality, for construction of the following roads, from N.E. corner, section 12-35-27 W., southerly to S.E. corner, section 1-35-27 W. Thence westerly to S.W. corner, section 1-35-27 W. From N.E. corner of N.W. ¼ section 15-36-24 W., along road diversion north of C.N. Ry. right-of-way, to point east of section 13-36-25 W. From N.E. corner, section 10-36-25 W. easterly to N.E. corner, section 12-36-25 W., thence north to C.N. Ry. track. From N.E. corner, section 32-36-25 W. northerly to N.E. corner, section 20-37-25 W. From N.E. corner, section 35-37-26 W., to N.E. corner, section 11-38-26 W. From N.E. corner, section 11-38-26 W. to N.E. corner, section 8-38-26 W. J. H. Cannon, secretary-treasurer.

Montreal, Que.—Tenders will be called for the reconstruction of Guy St. and Cote des Neiges Rd., and for the repair of Notre Dame St. West, between Chaboillez Sq. and Dominion St. City engineer, Mr. Doucet.

Montreal, Que.—The reconstruction of St. Lawrence Blvd., from Craig St. to Ontario St., and of St. Denis St., between St. Catherine St. and Ontario St., is to be undertaken by the Public Works Department at once, and the work is to be rushed through to completion before the fall.

Odessa, Ont.—Contract has been awarded for construction of bridge to Gibson & McGinnis. Construction will commerce as soon as the bridge contract at Westbrook, Ont., has been completed. Charles Grass, county superintendent, Westbrook.

Orillia, Ont.—Town council will construct pavements at the intersections at Penetanguishene, Neywash and West St., and contemplate paving Matchedash St. from Coldwater to Colborne St. D. C. Anderson, mayor.

Orillia, Ont.—Tenders will soon be called by town council, for construction of sidewalk on north side of Mississaga St. from Matchedash to Front St. D. C. Anderson,

Orillia, Ont.—A new concrete and steel bridge over the Narrows is being constructed by the G.T. Ry.

Oshawa, Ont.—Contract has been awarded by town council for construction of concrete sidewalks to T. B. Mothersill, Oshawa. W. G. Worden, town engineer.

Pembroke, Ont.—Council contemplates construction of granolithic sidewalks on south side of Cemetery St., from Dominion St. to James St. W. J. Moore, town engineer.

Rosser, Man.—Tenders will be received by W. H. Beachell, secretary-treasurer, up to 12 o'clock noon, September 15th, 1919, for the following work: Grading about 10,000 yards on the Lilyfield Rd.; for grading and ditching about 1,000 yards on the C.P.R. Rd., between Bergen and Rosser; gravelling about five and one-half miles on C.P.R. Rd., and for gravelling about one and one-half miles on the Rosser Rd. Specifications can be seen at the office of the Highway Commissioner, Winnipeg.

St. Armand Sta., Que.—No tenders were received by the Good Roads department, Quebec, for gravelling roads in parish of St. Armand West. G. Bradley, secretary-treasurer.

St. Bruno de Montarville, Que.—Tenders will be received until 7 p.m., September 15th, by Frederic Huet, secretary-treasurer, for the construction of a gravel road, the road known as "Chemin des Vingt," culverts and ditches included, over a distance of about 12,363 feet. Plans and specifications can be obtained at the office of the secretary-treasurer.

St. John's, Que.—Contract has been awarded to the Richelieu Quarry Co., for improvements of St. Luc Rd. from city limits of St. Johns to town limits of Laprairie.

Trail, B.C.—Contract has been awarded by city council for construction of sidewalks and retaining wall to the Grand Forks Concrete Co. Contract price, $7,900. Rejected tenders, J. H. Freney, Rossland, $15,845; Medby & Vestauney, $13,025, R. D. MacDonald, $12,600. The following tenders were received from cross-walks, J. H. Freney, $1,112; Grand Forks Concrete Co., $1,160; R. D. MacDonald, $1,056. W. E. B. Monypenny, clerk.

Vancouver, B.C.—On September 30th ratepayers will vote on a by-law to provide $160,000 for rebuilding and repairing the Connaught bridge, and another for $100,000 for street improvements. City clerk, W. McQueen.

Windsor, Ont.—On Sept. 20th, the ratepayers will vote on by-laws to raise $30,000 for sidewalks, and $20,000 for the purchase of two street flushers.

Windsor, Ont.—City council proposes to construct the following concrete sidewalks: Gladstone Ave., e.s., Ontario St. to Terminal Ry., 2,900 ft., w.s., Giles Blvd. to Terminal Ry., 2,800 ft.; Moy Ave., both sides, Giles Blvd. to Terminal Ry., 2,800 ft.; Hall Ave., both sides, Giles Blvd. to Terminal Ry., 2,800 ft.; Benjamin St., w.s., Ottawa St., 300 ft.; Langlois Ave., e.s., Ottawa St. to 200 ft. s. of Banwell St., 800 ft., w.s., Ottawa St. to Tecumseh Rd., 3,600 ft.; Huron St., s.s., alley w. of Pierre to Hall Ave., 400 ft., and from Moy Ave. to easterly city limit, 450 ft.; Ottawa St., s.s., eastern city limit to Pierre Ave., 1,200 ft., n.s., Pierre Ave. to Marion Ave., 350 ft., and from Moy Ave. to Gladstone Ave., 350 ft.; Goyeau St., e.s., end of walk to Ellis Ave., 400 ft., w.s., end of walk to 300 ft. w. of Shepherd St., 650 ft.; Dufferin Pl., w.s., Tecumseh Rd., w. 100 ft., and Ellis St., 400 ft. w., e.s., Giles Blvd., s. 500 ft., and from Wyandotte St. to Ann St., 900 ft., Pelissier St., w.s., end of walk to 1,100 ft.; e.s., from Giles Blvd. w. 300 ft.; Janet Ave., w.s., end of walk s. 100 ft.; Louis Ave., e.s., Erie St. to Giles Blvd., 1,260 ft., and w.s., end of walk to Giles Blvd., 800 ft.; Cameron Ave., e.s., end of walk, 200 ft. s. of Wyandotte St., 850 ft.; McKay Ave., e.s., Wyandotte St. to Union St., 850 ft.; Pine St., s.s., Dougall Ave. to Janet Ave., 900 ft.; Ontario St., w.s., Church St. to Bruce Ave., 400 ft. Estimated cost, $30,000. M. A. Brian, city engineer; M. A. Dickinson, city clerk.

Winnipeg, Man.—City council intends to construct granolithic sidewalks on several streets. City clerk, C. J. Brown.

Winnipeg, Man.—City council intends to construct the following asphalt pavements: Logan Ave., from East St. to McPhillips St., estimated cost $128,948; Montrose St., from Academy Rd. to Wellington Cres., estimated cost $6,955; and Montrose St., from Academy Rd. to Kingsway, estimated cost $14,386. City clerk, C. J. Brown.

Winnipeg, Man.—A. McGillivray, Provincial Highway Commissioner for Manitoba, who recently returned from an inter-provincial conference of government good roads representatives, announced that Manitoba's share of the $20,000,000 appropriation by the federal government for construction of good roads will amount to $1,602,265.

Woodworth, Man.—Tenders will be received by W. V. Stevenson, secretary-treasurer, Woodworth Municipality, Harding, Man., up to noon, September 13th, for the construction of three concrete culverts. Plans and specifications may be obtained from the office of the Highway Commissioner, Parliament Buildings, Winnipeg, or from Mr. Stevenson.

York Township, Ont.—Township council intends to extend Woodville Ave. from its present westerly terminus, westerly to Don Mills Rd. W. A. Clarke, township clerk.

York Tp., Ont.—By-laws calling for the building of three miles of concrete sidewalks, four or five feet wide, with a 6-inch curb, have been adopted by the township council. Township clerk, W. A. Clarke, 40 Jarvis St., Toronto.

WATER, SEWAGE AND REFUSE

Amherstburg, Ont.—By-law is being prepared providing for construction of extensions to the Watson Iler drain, 1st concession, Township of Colchester South. Estimated cost, $2,351. J. H. Madill, township clerk.

Belleville, Ont.—City council intends to construct sanitary sewers on several streets. Estimated cost, $13,891.57. City clerk, J. Wilfred Holmes.

Galt, Ont.—City council passed a by-law for the construction of a sewer on Simcoe St. City engineer, W. H. Fairchild.

Gravelbourg, Sask.—The town council has made application to the Local Government Board for permission to construct a waterworks and sewage disposal plant. Town clerk, George Hebert.

Lethbridge, Alta.—The ratepayers defeated a by-law to spend $35,000 for the installation of water meters.

Lindsay, Ont.—Engineer Oliver Smith presented a plan to the town council, showing a system of storm sewer construction. Estimated cost, $6,000. The matter will be dealt with later.

London, Ont.—City council intends to construct a sanitary sewer system estimated to cost $88,737.50. City clerk, S. Baker.

London, Ont.—Tenders will be received until 4 p.m., (daylight saving), September 15th, for construction of approximately 1,700 lin. ft. 15-in. tile, sewers, 1,800 lin. ft. 12-in. tile sewers, 800 lin. ft. 10-in. tile sewers, and 7,000 lin. ft. 8-in. tile sewers. H. A. Brazier, city engineer.

London, Ont.—Manager Buchanan, of the Utilities Commission, says the commission will not undertake anything further than the building of a new reservoir at Springbank in connection with the plan to increase the water supply of the city next year. His estimate on the cost of this work is $200,000. An outside engineer will be asked to prepare an estimate before the plans are completed. In connection with the new reservoir it is planned to build a new supply line from Springbank to the city, but this part of the work will not be undertaken until 1921 in all probability.

Moose Jaw, Sask.—Tenders for the construction of the Britannia Park infiltration gallery project were received as follows: C. U. McManus Co., $27,709.40; Carter-Halls-Aldinger Co., $33,653, and P. W. Graham, $35,761. City council awarded contract to C. U. McManus Co. G. D. Mackie, city engineer.

Moose Jaw, Sask.—Four tenders were received for extensions to sewer and water connections as follows: A. E. Hamilton, $15,373.79; C. U. McManus, $15,934.75; Carter-Halls-Aldinger Co., $18,129.30; P. W. Graham, $19,435. City council awarded contract to C. U. McManus Co. G. D. Mackie, city engineer.

Nelson, B.C.—In a report to council, which was adopted, A. L. McCulloch, engineer, recommended the present 14-in.

Brant Road, Galt, Ont. Tarvia modified modern pavement built in 1911. Treated with "Tarvia-B" in 1916.

A view of St. Andrews Street, Galt, Ont. Surface-treated with "Tarvia B" in 1916 and 1918.

Tarvia

Preserves Roads Prevents Dust

Tarvia Streets in Galt, Ont., have made good—

BRANT ROAD, shown above, was constructed in 1911 with "Tarvia-X." In 1916 it was treated with "Tarvia-B." The photograph was taken two years later, and a finer street would be hard to find. Not a hole or a patch or a ravelled spot in the whole stretch !

And this street can be *kept* in first class condition for many years with an appropriate Tarvia treatment at very small cost.

The small photograph in the oval shows St. Andrew's Street, built originally as a waterbound macadam street and treated with "Tarvia-B" in 1916 and again in 1918.

This street shows what can be done by surface-treating old water-bound macadam with Tarvia if it is taken in time. Systematic surface treatments with Tarvia will keep this road in fine condition indefinitely.

Tarvia is ideal for city and town residental streets because a Tarvia street is dustless and mudless and easy to keep clean. Taxpayers like Tarvia streets because of these features, and also because they can be maintained very economically.

Galt is only one of the scores of Canadian cities and towns that are solving their street problems with Tarvia.

If your community is facing any road construction or re-construction problems, or if you require an efficient dust preventive, road preserver or patching material, it will certainly pay you to investigate Tarvia.

Special Service Department

This company has a corps of trained engineers and chemists who have given years of study to modern road problems. The advice of these men may be had for the asking by anyone interested. If you will write to the nearest office regarding road problems and conditions in your vicinity, the matter will be given prompt attention. Booklets free.

MONTREAL TORONTO WINNIPEG
VANCOUVER ST. JOHN, N.B.
HALIFAX, N.S. SYDNEY, N.S.

pipe line, supplying water to the town, be overhauled until such time as it is found possible to replace the entire pipe line. Surveys to be undertaken to ascertain amount of water available from Cottonwood Creek for waterworks purposes. In the near future, to construct a new conduit from a point below east fork of the creek, an additional length of 4,000 or 4,300 lin. ft., giving an increase of 200 ft. head. Total length of new line, approximately 14,500 lin. ft. Pipe recommended, 10-in. to 12-in., 14 gauge, steel pipe. Estimated cost of repairs, $42,000. Estimated cost of new pipe, $44,000 to $50,000. Present capacity of conduit, 1,750,000 gals. per day. Future capacity, 3,000,000 gals. per day.

Orillia, Ont.—Town council has decided to construct a storm sewer along Neywash St. to the lake. D. C. Anderson, mayor.

Oshawa, Ont.—Contracts have been awarded by town council for construction of 15-in. sanitary sewers to J. H. McKnight Construction Co., Ltd. Contract price, $27,880.W. G. Worden, town engineer.

Regina, Sask.—It is stated that the provincial government is considering a scheme to divert water from the South Saskatchewan River, near Elbow, to supply Moose Jaw, Regina and other cities and towns along the line.

St. John's, Que.—City council authorized construction of a sewer on Jacques Cartier St. from St. Charles to St. Paul.

Windsor, Ont.—The Essex Border Utilities Commission has awarded the contract for the construction of the Walkerville sewage pumping station to the R. Westcott Co., Ltd., of Windsor. The construction is to be started at once. Contract price is in the neighborhood of $13,000.

Windsor, Ont.—City council will submit by-law to ratepayers providing for construction of water mains on the following streets: Howard Ave., from Tecumseh Rd. to south limits; Martin St., from McEwan Ave. to Campbell Ave.; Brant St., from Pierre Ave. to alley east of Langlois; Ottawa St., from Gladstone Ave. to Hall Ave.; Moy Ave., from Ottawa St. to south limits; Hall Ave., from Ottawa St. to south limits; Windsor Ave., from lot No. 31 to Shepherd Ave.; Shepherd Ave., from Windsor Ave. to McEwan Ave. M. E. Brian, city engineer.

York Tp., Ont.—The Municipal and Railway Board has approved of the plans submitted for 12-inch trunk water mains on Bathurst St. and Connaught and Lonsdale Aves.

"EXTENSION OF TIME"

The time for receiving tenders for the "Office Furniture" for this building, is hereby extended to Noon, September 13, 1919.

JOHN A. PEARSON, Architect,
J. O. MARCHAND, Associate,
Centre Block, Parliament Hill, Ottawa.

Ottawa, September 5, 1919. 348

WANTED.—A first-class, Experienced, Operating Engineer, to take full charge, and be capable of managing Water Works Plant in Ontario City, with High-Duty Pumps; also Steam Turbine and Electrically Driven Motor Pumps, with Staff of Operating Engineers and Firemen. None but thoroughly competent man need apply, stating experience and references. Address Box 7, *The Canadian Engineer*, Toronto.

PATENT NOTICE.—Any one desiring to obtain the invention covered by Canadian Patent No. 179219, granted September 11th, 1917, to Dennis H. McBride, of New York City, U.S.A., for rosary, may do so upon application to the undersigned, who are prepared to supply all demands on the part of the public for the invention and from whom full information may be obtained. Fetherstonhaugh and Co., 5 Elgin St., Ottawa, Canada. Russel S. Smart, resident. 349

York Tp., Ont.—The township council awarded contracts for over four miles of 6-inch water mains and passed by-laws providing for several miles more. The contracts, amounting in all to $100,000, were awarded to Peter Iles, the Murphy Contracting Co. and Angelo Cavotti. The work is for Oakwood, Mount Dennis and Swansea. This year the council will have spent $350,000 on water mains. Previous expenditures have amounted to $600,000.

York Tp., Ont.—Preliminary steps will be taken by the township council to lay water mains over a mile in length in the Spadina Road district, as follows:—Forest Hill Road from Spadina Road to Huron Street, 800 feet; Huron Street, from Coulson Street to Forest Hill Road, 2,800 feet; Burton Road, from Kendal Avenue to Brunswick, or to the west end, 320 feet; Clairmont Road, from Bathurst to east end, 496 feet; Westmount Drive, from Bathurst east and south to the south end, 1,291, a total of 5,707 feet. Engineer, Frank Barber, 40 Jarvis St., Toronto.

LIGHT, HEAT AND POWER

Cobalt, Ont.—The Wendigo Power Co., with head office in Guelph, Ont., has been incorporated under the laws of the Dominion for the purpose of developing hydro-electric power on Wendigo Lake and certain parts of the Blanche River, including the storage rights on upper waters. The company's plant will be located some twenty miles south of Larder Lake, and officials claim that a ready sale of 2,000 horse-power, to be developed immediately, is assured. The intention of the management is finally to develop 3,000 to 4,000 horse-power.

Hanley, Sask.—Tenders addressed to A. Holm, secretary-treasurer, Hanley, Sask., will be received up to 6 p.m., September 24th, 1919, for the supply, delivery and erection of machinery and materials and the performance of certain works. Murphy and Underwood, Saskatoon, Sask., consulting engineers. (See official tender advertised in this issue.)

Minitona, Man.—Tenders addressed to J. W. Pugsley, secretary, Department of Railways and Canals, Ottawa, will be received until 12 o'clock noon, Monday, September 29th, 1919, for the Bobcaygeon Section, Trent Canal. Plans and specifications can be seen at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer, Trent Canal, Peterborough, Ont.

Winnipeg, Man.—Thomas Kelly and Sons, contractors, are the successful contractors for the Big Turkey Creek sewerage construction, Kansas City, Missouri. Contract price, $2,500,000.

Welland, Ont.—By-law has been passed by city council providing for extensions and improvements to the Hydro-Electric Power system. Estimated cost, $35,000. C. M. Stapf, clerk.

York Township, Ont.—Township council contemplates purchase of lines of the Toronto Electric Light Co., located in township. Construction of the Hydro lines will begin immediately.

RAILWAYS

Hamilton, Ont.—Plans have been prepared by the Hydro-Electric Power Commission for construction of radials from Hamilton to Toronto. It is expected that work will commence soon.

London, Ont.—According to an announcement recently made by Sir Adam Beck, western Ontario is to have a new hydro radial running from Hamilton through Brantford, Burford, Woodstock, Ingersoll and Dorchester to join the municipally-owned London and Port Stanley Railway between this city and St. Thomas, probably in the vicinity of Westminster.

Preston, Ont.—Construction of track has commenced on the Preston-Kitchener and on the Preston-Hespeler lines of the Grand River railway.

Prince Albert, Sask.—The railway from Fort McMurray country to Prince Albert, proposed by Lord Rhondda, previous to the recent war, may now be constructed.

Toronto, Ont.—Works Commissioner R. C. Harris has sent on to the city solicitor, to be forwarded to the Ontario Railway Board, the plans for the Mount Pleasant car line. The plans provide for an expenditure of slightly under $1,000,000 for three miles of track, via St. Clair Ave. and Mount Pleasant, to Glen Echo.

FACTORIES AND LARGE BUILDINGS

Barons, Alta.—Board of education will erect an eight-room school. Architect, Mr. Whiddington, Lethbridge.

Belleville, Ont.—Tenders addressed to H. F. McNaughton, secretary, Parliament Buildings, department of public works, Toronto, will be received until Tuesday, September 16th, 1919, for a single and double cottages to be erected on the grounds of the Ontario School for Deaf, Belleville. Plans and specifications may be seen at the office of the bursar at the school and at the department of public works, Toronto.

Calgary, Alta.—Construction work will start October 1st on a new "Allen" theatre, to be located on Eighth Ave. Including the cost of the property, the new theatre will be erected at an expenditure of approximately $500,000. Architect, C. Howard Crane, Windsor, Ont.

Cap de la Madeliene, Que.—Contract for building a new office for the Banque Nationale has been awarded to Joseph Blais, of Levis, P.Q., for $19,000.

Charlottetown, P.E.I.—H. and S. Lowe have been awarded the contract for building a new machine shop for Bruce Stewart and Co., Ltd.

Edmonton, Alta.—Board of education will erect a two-roomed school at Forest Heights, extension to Parkdale school $15,000, repairs to King Edward school $2,000, eleven portable schools of one room each at Norwood, Oliver, Alex. Taylor, McAulay, Allendale and Riverdale. Total estimated cost, $62,000.

Fort William, Ont.—A. Snelgrove has purchased a site for the erection of an elevator. Construction work will probably begin next spring.

Fort William, Ont.—A company has been formed to construct and operate a large, modern skating rink building, to be completed and in operation by December 1st. Estimated cost, $75,000. Charles Birkett, chairman of committee.

Guelph, Ont.—A movement is on foot for the construction of a new skating rink.

Hamilton, Ont.—A new theatre is to be erected at the Delta, and will be controlled by the same management which now operates the Queen's and Empire on Barton St. and the New Strand on King St. East.

Hamilton, Ont.—It has been announced that the T. Eaton Co., Ltd., has decided to erect an addition to its factory here at a cost of $100,000, and that Wood, Alexander and James will shortly begin the erection of a warehouse at the corner of King William St. and Fergus Ave. costing $280,000.

Kitchener, Ont.—Application has been made by the Ames Holden Co. for a permit to erect in this city a two-story factory 100 by 145 ft. The contract has been let to Dunker Bros.

Montreal, Que.—Contract has been awarded by the Montreal Locomotive Works, to D. G. Loomis and Sons, for extensions to plant.

Montreal, Que.—Contract has been awarded by the United Shoe Machinery Co. to D. G. Loomis and Sons, for extensions to plant. Contract price, $44,000.

Montreal, Que.—I. H. Laing has awarded contract for construction of stores and warehouses to Archambault and Co., 610 Lafontaine Pk. Contract price, $60,000.

Montreal, Que.—Contract has been awarded by the National Breweries, Ltd., for addition to plant, to Atlas Construction Co. Contract price, $450,000.

Moose Jaw, Sask.—City council awarded the following contracts for the erection of comfort station: General work, H. E. Forbes, $6,558.60; heating and plumbing, Moose Jaw Heating and Plumbing Co., $3,493; marble and tile work, Regina Marble and Tile Co., $2,773.25.

Orillia, Ont.—Plans have been prepared and tenders will soon be called for construction of a new stone memorial hospital on Mississaga St. Architect, E. Bird, Toronto. G. Thomson, chairman of hospital board.

Oshawa, Ont.—The purchase of all material for the new buildings of the General Motors Co. is in the hands of the general contractors for the work, Canadian Stewart Co., Ltd., Dominion Bank Building, Toronto.

Oshawa, Ont.—Tenders have been called by B. H. Prack, Lumsden Building, Toronto, for excavating, structural steel, steel sash, roofing and mechanical trades in connection with the erection of five new buildings at the plant of The Pedlar People, Ltd. The buildings will be of the following dimensions: 2 storeys, 80 by 360 ft.; 2 storeys, 80 by 365 ft.; 2 storeys, 70 by 285 ft.; 1 storey, 60 by 285 ft.; 1 storey, 70 by 250 ft. All will be steel construction with brick walls and concrete floors.

Ottawa, Ont.—The time for receiving tenders for the office furniture for the Parliament Buildings has been extended to noon, September 13th, 1919. Architect, John A. Pearson, Centre Block, Parliament Hill, Ottawa.

Point Grey, B.C.—Plans have been prepared for a new building on Fourth Ave. for the Boys' Industrial Home. Estimated cost about $80,000. Government architect Middleton.

Provost, Alta.—Tenders will be received by the Board of Trustees School District No. 2670, Provost, at the office of Andrew Steele secretary-treasurer, Edmonton, up to noon, Saturday, September 20th, for the erection of a school house. Plans and specifications may be obtained from the secretary-treasurer.

Quebec, Que.—Contract has been awarded by the department of public works, Ottawa, for construction of marine warehouse at Quebec, to Peters, Ltd., Quebec.

Regina, Sask.—H. G. Smith, Ltd., will build a warehouse building, 75 by 112 ft., on Broad St., between Sixth and Fifth Avenues, at a cost of $30,000.

Regina, Sask.—Tenders will be received by D. C. McNab, deputy minister, department of telephones, Regina, until one o'clock p.m., Monday, September 15th, 1919, for the erection of telephone exchange buildings at Kamsack, Indian Head, Maple Creek, Melville and Moosomin. Plans and specifications may be seen at the office of Storey and Van Egmond, architects, Regina, or at the telephone exchanges in the towns above named.

Renfrew, Ont.—The Renfrew Refrigerator Co. will construct immediately new additions which will double their present floor space. M. C. Fuller.

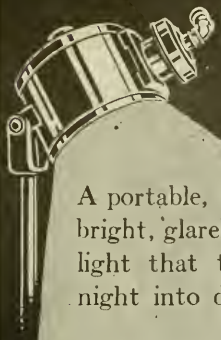
Sarnia, Ont.—The Board of Education authorized the chairman and secretary to sign the amended contracts with S. B. Coon and Son, architects, for the construction of the new Collegiate and Technical School.

Saskatoon, Sask.—A lagre skating rink building, with seating accommodation for 3,000 people, will be erected immediately at the corner of Fourth Ave. and Spadina Cres.

Selkirk, Man.—School board will erect collegiate building. Architect, E. D. Tuttle, McArthur building, Winnipeg.

St. Catharines, Ont.—The Board of Education will purchase a site for the erection of a new Collegiate Institute. Building operations will likely commence next spring. Estimated cost, $180,000 to $200,000.

St. John, N.B.—Gandy and Allison will construct a reinforced concrete and steel warehouse.



ELECTRIC DAYLIGHT

WITH THE

Northern Electric

DAVIS

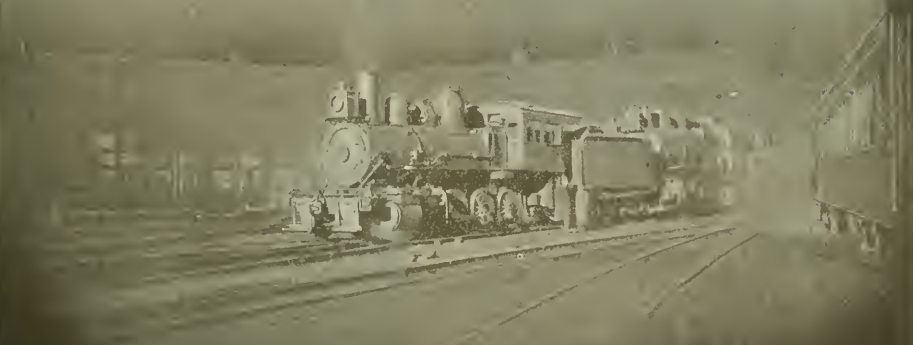
FLOOD LAMP

A portable, bright, glareless light that turns night into day.

It can be diffused over large areas or projected in a solid beam.

The light that lights Niagara

These Flood Lamps are ideal for lighting railroad terminals—freight yards—round houses—transfer yards and platforms—wrecking equipment – wherever working light is needed.



They can be used anywhere—no arc lamp trimming—no moving parts—no permanent wiring.
Write for our folder and tell us your lighting problems.

Northern Electric Company

LIMITED

MONTREAL OTTAWA WINNIPEG CALGARY
HALIFAX TORONTO REGINA VANCOUVER

St. Thomas, Ont.—Tenders will be received until 12 o'clock noon, September 17th, by the board of education for masonry, carpenter work, etc., required in construction of a one-story, six-roomed annex to Myrtle St. school. N. R. Darrach, 430 Talbot St., St. Thomas, architect.

Sydney, N.S.—Contract has been awarded by the Sydney Hotel Co. for construction of concrete and steel hotel building to the G. A. Fuller Co. Capacity of hotel, 170 rooms.

Toronto, Ont.—Board of control sent on to the city council a by-law providing for an issue of debentures amounting to $500,000 for new schools.

Toronto, Ont.—The city architect has issued a permit for the erection of a public school on the corner of Glen Grove Ave. and Rosewell, at a cost of $147,000.

Toronto, Ont.—According to an announcement made by Mayor Church the citizens may probably be asked on January 1st next to vote $1,500,000 for new buildings at the Exhibition grounds, including a live stock arena, estimated to cost $1,000,000.

Toronto, Ont.—Wood, Gundy and Co., C.P.R. Building, have purchased from Strathy and Orpen for $140,000, the five-story building at the north-east corner of King and Victoria Streets, and will spend $70,000 upon internal alterations to the building.

Toronto, Ont.—Esenwein and Johnson, 775-797 Ellicott Sq., Buffalo, are the architects, and Dickie Construction Co., Ltd., Ryrie Bdg., Toronto, are the contractors for the construction of new 500-room extension to the King Edward Hotel. These firms have handled all the construction work, in Canada, of the United Hotels Co.

Trail, B.C.—The Trail Athletic Association intends to construct a large grandstand and improve the athletic grounds.

Waterloo, Ont.—The town council passed a by-law placing the town under the Ontario housing act, and appointing a housing commission. This was done in connection with an offer from the Dominion Rubber Co., to build 100 houses in Waterloo.

Windsor, Ont.—It has been announced that Max Allen, manager of the Windsor Theatre, and ex-alderman Simon Meretsky have purchased property at the corner of London St. and Elm Ave., upon which a $50,000 modern film playhouse will be erected in the spring.

Winnipeg, Man.—W. A. Irish is erecting a brick factory at the corner of Notre Dame Ave. and Erin St., for J. H. Parkhill. Cost, $49,900.

Winnipeg, Man.—The city is going ahead with its housing scheme immediately, and is prepared to spend up to $276,000 on the scheme this year.

Winnipeg, Man.—The C.N. Ry. plans to construct a number of hotels in the mountains along the railway. First hotel to be constructed at Jasper Park, B.C. W. Pratt, manager of hotel services.

Woodstock, Ont.—Canadian Linderman Co. will resume operations on completion of alterations to plant. F. Backstrom, Muskegon, Mich.

Woodstock, Ont.—Bell Telephone Co. will construct a two-story central exchange on Graham St. Construction will probably commence this fall.

Windsor, Ont.—On September 20th the ratepayers will vote on a by-law to grant certain concessions to the Lamb Railway Service Co., in return for the company undertaking to erect a $10,000 factory and to the Fisher Closed Body Co., who propose to erect a five-story building.

Yorkton, Ont.—Arrangements have been completed with H. Bronfman, of this city, for the erection of a new "Allen" theatre. The erection of the Yorkton theatre is said to be the first step in the erection of a large number of theatres in the small cities and towns of Canada by the Allen theatre enterprises.

York Township, Ont.—By-law has been passed by township council providing for construction of two school houses for school section No. 15. Estimated cost, $172,650. W. A. Clarke, township clerk.

MISCELLANEOUS

Comox, B.C.—Contract has been awarded by department of public works, Ottawa, for construction of wharf to the Fraser River Pile Driving Co. Contract price, $17,358. R. C. Desrochers, secretary.

Hamilton, Ont.—Tenders addressed to H. F. McNaughton, secretary, Department of Public Works, Parliament Buildings, Toronto, will be received until Monday, September 15th, 1919, for concrete reservoir to be built on the grounds of the Ontario Hospital, Hamilton, and for an addition to Nurses' Home, Ontario Hospital, Kingston. Plans and specifications may be seen at the office of the Bursar at the above institutions, and at the Department of Public Works, Toronto.

Humboldt, Sask.—Town council will install a centrifugal, direct-connected motor-driven pump, complete with automatic switch. Capacity of pump, 100 gals. per min. F. W. D. Thompson, town clerk.

Kingston, Ont.—Board of works recommended to council purchase of a Sawyer-Massey single tractor 20 h.p. engine. Estimated cost, $2,200. Ald. Graham, chairman, board of works.

Lasalle, P.Q.—Ratepayers defeated the by-law which provided for the borrowing of $131,000 for road improvements, extending and grading of streets and laying water pipes.

Lindsay, Ont.—Tenders will soon be called by the department of railways and canals, Ottawa, for rebuilding wharf. Estimated cost, $10,000.

Little River, N.S.—Tenders, addressed to R. C. Desrochers,, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Thursday, September 25th, 1919, for repairs to the breakwater at Little Brook, Digby County, N.S. Plans may be seen, and specification obtained at the department of public works, at the office of the district engineer, Halifax, N.S., and at the post office, Little Brook, N.S.

Naramata, B.C.—Tenders will be received until 12 o'clock noon, September 22nd, by the department of public works, Ottawa, for construction of wharf. Plans, etc., at offices of district engineer, Chase, B.C., post offices at Vancouver and Naramata, B.C. R. C. Desrochers, secretary.

Scotch Cove, White Point, N.S.—Tenders will be received until 12 o'clock noon, September 17th, by the department of public works, Ottawa, for construction of extension to breakwater at Scotch Cove, White Point, Victoria County, N.S. Plans, etc., offices of district engineers, North Sydney, N.S., Halifax, N.S., post office White Point, N.S. R. C. Desrochers, secretary.

St. Johns, Que.—City council has authorized the city engineer to purchase a cut-off valve for the water tower.

St. Thomas, Ont.—Tenders, addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until 12 o'clock noon, Thursday, September 18th, 1919, for alterations to plumbing and toilet rooms, post office, St. Thomas, Ont. Plans and specifications may be seen at the offices of the chief architect, department of public works, Ottawa; the caretaker, public building, St. Thomas, Ont., and the superintendent of Dominion buildings, Postal Station "F," Toronto, Ont.

Welland, Ont.—Council proposes purchase of a fire truck for the new fire station under construction at corner of Hellems Ave. and Division St. Estimated cost of new equipment, $15,000. Deputy fire marshal Shannahan.

Winnipeg, Man.—City council will purchase 3,000 lin. ft. of 2 x 5 in. cotton rubber-lined fire hose. C. J. Brown, city clerk.

Winnipeg, Man.—City engineer has been authorized to call for tenders for concrete mixers. W. P. Brereton, city engineer.

Winnipeg, Man.—City council will purchase a small batch concrete mixer, capacity, about one-third yard. C. J. Brown, city clerk.

Windsor, Ont.—On September 20th, the ratepayers will vote on a by-law to raise $15,000 for the purchase of a motor-driven fire engine.

The Canadian Engineer

A Weekly Paper for Civil Engineers and Contractors

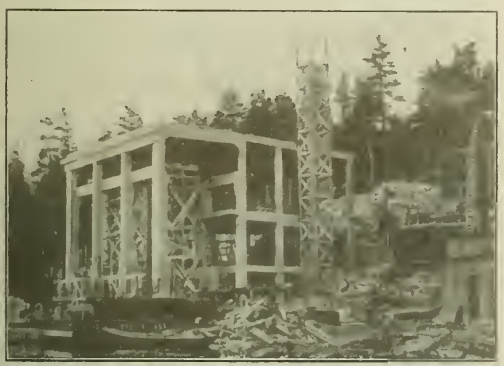
Kipawa Co.'s Pulp Mill and Power Development

First Unit of Bleached Sulphite Pulp Mill Nearing Completion — Ultimate Capacity, 30,000 Tons of Pulp Per Annum — Development of Gordon Creek Utilizes Approximately 200 Ft. Net Head — Wood Stave Power Pipe Line 8 Ft. in Diameter

WITHIN a couple of months the Kipawa Company, Ltd., will have completed the first portion of their construction program in connection with the new pulp mill and townsite at Timiskaming, P.Q.

Situated on the Ottawa river, at the outlet of Gordon creek and adjacent to the Dominion government dams forming the toe of Lake Timiskaming, the site of this new pulp mill is ideal. Pulpwood may be obtained from any or all of four distinct sources of supply: (1) From the northern end of Lake Timiskaming by towing; (2) from the Kipawa Lake district through Kipawa river and chutes to Lake Timiskaming, and thence to plant by towing; (3) from the Kipawa Lake district through Gordon creek, which is an improved creek for lumber interests; and (4) from the south by rail over the Mattawa-Timiskaming branch of the Canadian Pacific Railway.

Upon completion of the full program of construction at Timiskaming, the Riordon Pulp & Paper Co., Ltd., which controls the Kipawa Company, Ltd., will have three large plants supplying material for the pulp and paper industry,



POWER-HOUSE ON LAKE TIMISKAMING

the existing plants being at Merritton, Ont., and Hawkesbury, Ont.

The new plant is being developed under a charter obtained from the province of Quebec, which has leased from the federal government all water rights in connection with the Kipawa lakes for power development or logging on either the Kipawa river or Gordon creek.

The interests of John Lumsden, owner of Lumsden's mill, and of other property owners were purchased, and a compact area of about eleven square miles was brought under control. (See *The Canadian Engineer*, issue of February 27th, 1919, page 260).

Ewing, Lovelace & Tremblay, consulting engineers, Montreal, were instructed to prepare topographical surveys, and Thomas Adams, town planning adviser to the Commission of Conservation, prepared preliminary plans for the model townsite. Upon this plan were located sites for approximately 280 buildings, including churches, hospital, convent, club, hotel, school and institute.

The first portion of the construction program includes the gate house and dam on Gordon creek at Lumsden's mill; a continuous, wood-stave pipe line of 8 ft. diameter; reinforced concrete forebay; riveted steel penstock; power house; combined railway and highway steel girder bridge; barking house; spur lines from the Canadian Pacific Railway; sidings in piling ground; wood room; digestor house; acid

SOME OF THE MILL BUILDINGS—FROM LEFT TO RIGHT, ACID TOWERS, DIGESTORS, SCREEN ROOM, MACHINE SHOP AND SHIPPING ROOM

towers; storage tanks; screen room; bleachery; press room; machine shop; transformer sub-station; boiler house; chimney; shipping room; elevators; office building; dwellings; roads; culverts under the Canadian Pacific Railway line to Kipawa; a continuous, wood-stave pipe line of 4 ft. diameter for supply of water to the mill; revolving screen house on mill supply line; sewers; water mains; pressure filter unit and pumping station.

Construction of the above-mentioned works is expected to be complete by the end of November, and the first unit of the mill will likely be in operation early in December. The first unit represents about 30% of the ultimate planned mill construction, but the work now being done on the townsite is only about 10% of that planned by Mr. Adams and the consulting engineers.

Future construction will include a second 8-ft. continuous wood-stave pipe line to the forebay, or else a tunnel through the hill from the dam at Lumsden's mills to the forebay, or possibly both tunnel and pipe line; four more steel penstocks; additions to power house and its equipment; sewage disposal works or sewage-chlorinating plant; street lighting system; filtered water mains crossing Gordon creek to mill; domestic water storage reservoir; hospital; school; churches and hotel.

To control the waters of Gordon creek at the site of the old Lumsden mill, the Kipawa Company have constructed a reinforced concrete dam with wing walls and foundations anchored to solid rock. The crest of the spillway, elevation

801.12 ft. above mean sea level, raises the level of the impounded water 10 ft. On the south side of the dam is constructed a brick gate house over a 48-in. cast iron gate, which will control the domestic supply through the 4 ft. continuous wood-stave pipe line to the mill. A Bristol recording thermometer has been installed in this building. Adjoining is the log chute opening required by the government

Dam at Lumsden's Mill

for use of the combined lumber interests along the Kipawa lakes. This opening is controlled by a wooden gate, hand operated.

The spillway of the dam consists of 5 bays, each approximately 6 ft. in width. Adjoining the spillway is a control chamber from which connection may be made in the future for operating a new mill, which may be erected on the site of the old Lumsden mill. This chamber is the source of supply for the old hydraulic turbine in the Lumsden mill, which drives the generator that supplies power for the

View of Kipawa Mill from Ontario Shore of Ottawa River, Looking Across Ontario Dam

electric lighting system now being used in the town and on the construction work.

Adjoining this chamber, and at the northerly end of the dam, is the inlet chamber which supplies water for the 8-ft. wood-stave power pipe line. This water is also controlled by a wooden gate, hand operated. The usual trash racks are fitted into both chambers.

Power Pipe Line

The 8 ft. power pipe line, which is completed, is of British Columbia fir, with continuous staves, bound by circular bands and supported on 10 by 10 in. wooden sills and blocks, with wedges in rock cuts and bents for fills.

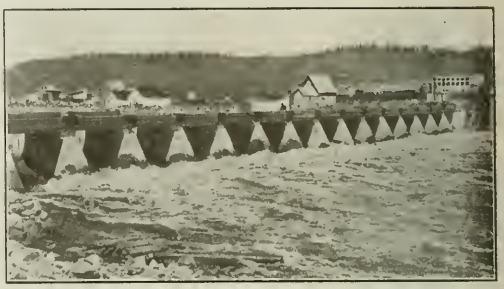
For the greater part of the length, the trench floor was lined to a depth of approximately 12 ins. with one-man-stone and fillers.

From inlet to forebay, the drop in elevation of the pipe line is approximately 20 ft. Along the line has been located 4-in. cast-iron, screw-flange connections, fitted with 4-in. screwed valves, to provide for emergencies such as fire. It was found advisable to clear the ground for 50 ft. on each side of the pipe line to reduce danger from forest fires, one fire which scorched the pipe for a short distance, having threatened the entire line with destruction.

A connection with the pipe line will be constructed to supply the proposed filtration and pumping station with water for domestic use throughout the town, and eventually for domestic use in the mill. The 4-ft. pipe line will continue to supply the mill with water for manufacturing purposes.

Forebay

The forebay is located on side hill. The foundations for the walls and the approaches to the penstock entrances, were drilled out of solid rock. The walls and superstructure are constructed of plain and reinforced concrete, being 36 ins. in



Another View of the Ontario Dam

width at the top and about 20 ft. in width at the base. In plan, the forebay is approximately square, with an area of about 10,000 sq. ft. and a depth of about 25 ft. from crest of spillway, which is 3 ft. below the top of the wall.

This forebay also serves as a surge tank and overflow chamber.

The northerly wall will eventually contain the outlet from the proposed tunnel, which will be approximately one mile in length through the hills to Gordon creek, with intake a short distance above the dam at Lumsden's mill.

Quebec Dam, Ottawa River

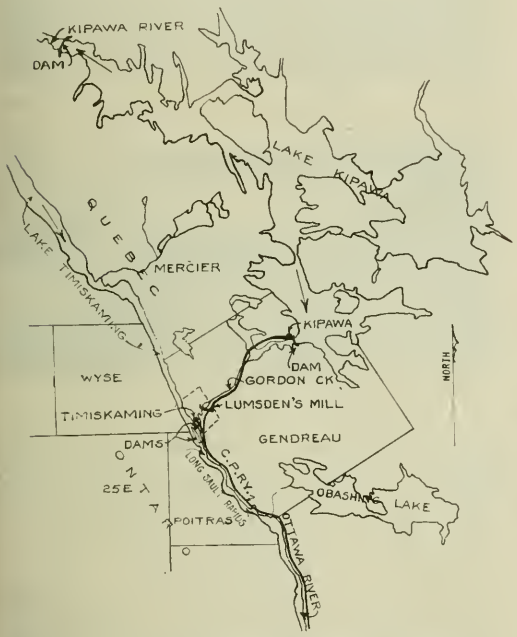
A channel has been drilled and lined with concrete in the rock within the forebay, from the proposed point of entry of the tunnel to the centre line, whence the excavation was carried to full depth and for the entire width. The rock forming that portion of the floor area that was not drilled and blasted, was capped with mass concrete.

The easterly wall contains two hexagonal openings providing for entrance of the present 8-ft. pipe line and for future duplication. The westerly wall contains spillway to Lake Timiskaming; one 36-in. dirty-water drainage-tile pipe; and three vertical rectangular gates, about 36 ins. in width, one of which is a high level, and the other two low level, overflows, hand operated.

The south wall contains the orifices leading through massed concrete to the penstocks, and controlled by hand-operated double gates. It is expected that these gates will later be fitted with electrical controls for rapid closing in emergencies.

Penstocks

At present, only one penstock has been constructed. It is an 8 ft. steel pipe, field riveted, with double-riveted lap joints. This penstock was constructed in a channel about 16 ft. in width by 10 ft. in depth, which was blasted from solid rock, and leads from the northerly orifice of the forebay to the power house, a drop in elevation of approximately 190 ft. Massed concrete anchor piers, four in number, are located between the two structures, and together with the penstock, will eventually be backfilled, thus reducing to a minimum the leakage in joints due to expansion and contrac-



MAP OF THE KIPAWA LAKE DISTRICT, SHOWING KIPAWA CO.'S TOWNSITE AT TIMISKAMING

tion. Within the power house, the flow from the penstock is divided by installation of a wye-branch, controlled by hydraulically-operated butterfly valves. The branches are designed to feed the present hydraulic turbine, No. 1, and a future turbine, No. 2.

Power House

The power house is located on the shore of Lake Timiskaming, about one-quarter mile north of the Canadian Pacific Railway station, and was constructed partially in cofferdam which extended into the lake in water of a depth of 35 to 40 ft. The building is massively constructed in steel and reinforced concrete, with curtain walls of pressed brick, and is plentifully supplied with windows fitted with interlocked double sash. It is divided into two main parts, separated on all floors by fire-resisting doors. The southern, or main, part of the building houses the turbines, generators, switchboards, pumps, governors, excitor and crane, while the remainder houses the transformers, storage room, oil storage, lightning arrestors and disconnecting switches (each of which is housed in a separate concrete box).

WOOD-STAVE PIPE LINE, 8 FT. DIAMETER

The turbine is of standard vertical type, 1,800 h.p. capacity, equipped with Lombard governor.

The capacity of power house will eventually be increased to 18,000 h.p. The southern wall is a wood curtain to permit extension.

Barking House

A short distance above the Dominion government's Quebec dam, and behind the Canadian Pacific Railway's main

POURING WALLS OF CONCRETE FOREBAY

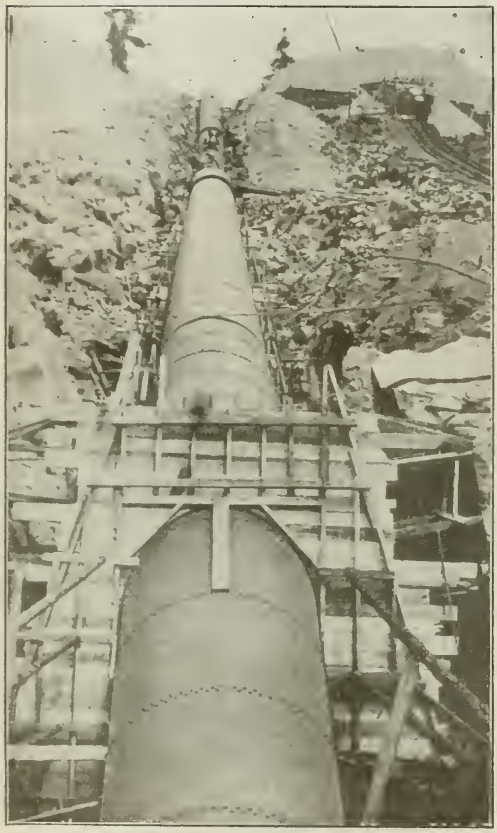
track from Timiskaming to Mattawa, is located the barking plant. The logs are lifted from the lake by endless conveyors, forming a jack ladder to an overhead conveyor platform crossing the railway. The logs are dumped into U-shaped troughs and are continually sprayed with water. In these troughs are revolving discs which rip the bark and pass the log from trough to trough to a loading platform on the spur line and thence to the piling ground. It is to be

DRILLING CHANNEL IN FOREBAY FLOOR

noted in connection with the barking house, that the logs are being handled in 16 ft. lengths instead of the customary shorter lengths. Experiments with this system of rotating discs were made with 4 ft. logs, and the idea has been enlarged to include logs 16 ft. in length.

Piling Ground

After passing through the barking house, the logs are conveyed over the Kipawa Co.'s sidings to the piling ground, in which are constructed five standard gauge tracks with 72-lb. rail. Straddling each track is a wide-gauge



Riveted Steel Penstock

track for an overhead traveller. The centre lines of the five standard gauge tracks have been located about 60 ft. apart to enable the overhead cranes to pile three rows of logs between the tracks and a fourth row on the track as the cars pull out. From the piling ground, the logs are reloaded and conveyed to the wood room, where they are chipped into pieces about ¼ in. by 1½ ins. in size. These chips are carried by an outside, closed conveyor to the top of the digestors.

Digestors and Acid Towers

The digestors, three in number, are housed in a reinforced concrete and brick building, six stories in height. Each digestor is constructed of steel plate, is 17 ft. in diameter and 56 ft. high, and is brick-lined for protection against acid corrosion. The capacity of each digestor per run is approximately 20 tons, and the ultimate capacity of the battery will be about 100 tons a day.

The acid towers are of reinforced concrete, circular, 9 ft. in diameter and 80 ft. high, and at present two in number. They, also, are lined with brick and are insulated by sheet lead. The limestone is loaded into these towers by an elevator located in adjoining rectangular structure. The acid, diluted, is stored in separate tanks which are located near the digestor building.

Screen Room, Bleachery and Press Room

The chips, after passing through the digestor, continue in pulp form through the screen room, where the pulp is thoroughly washed and screened. From the screen room, the pulp goes to the bleachery, and then to the machine shop, where it is rolled into sheets of convenient sizes and pressed into blocks ready for shipment to the paper mills, the hydraulic presses removing nearly all of the moisture.

Boiler House

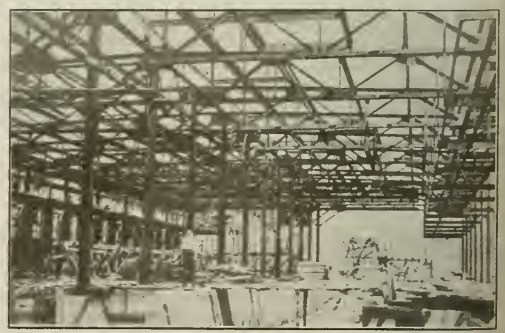
The acid towers digestor room, screen room, bleachery, machine shop and shipping room, are constructed to a uniform street line. Across this street are located the transformer sub-station, boiler house and chimney. The boiler

Jack Ladder and Conveyor Platform

house, also constructed in concrete and brick, contains five Babcock & Wilcox boilers of the superheater type, fitted with economizers, automatic stokers and appliances for using bark as fuel. The chimney, which is about 16 ft. in diameter at the base, is approximately 200 ft. high and was erected by the Canadian Custodis Co.

4-ft. Wood-Stave Pipe Line

The water to be used throughout the mill will be obtained from the dam at Lumsden's mill through a continuous



Machine Room During Construction

wood-stave pipe line 4 ft. in diameter, constructed on bents and sills, supported by a 12-in. floor of boulders and stone, and situated on the southerly side of Gordon creek. The water, controlled by a cast-iron valve in the gate house at

the dam, passes through revolving screens in a building at present under construction immediately adjacent to the gate house. These screens are horizontal, 5.5 ft. in diameter, and 11 ft. long, revolving at 5 r.p.m., and are electrically controlled.

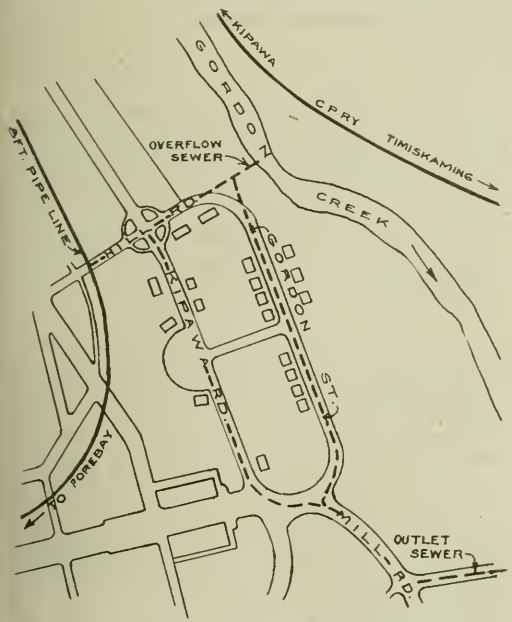
Sewer and Water Mains

Following the recommendations of R. S. & W. S. Lea, consulting engineers, Montreal, it was decided to construct

ANOTHER VIEW OF THE MILL BUILDINGS—WHEN COMPLETED THE CAPACITY WILL BE 100 TONS DAILY

sewers and water mains along Hill Road, Kipawa Road, Gordon Street and Mill Road.

Mains along these streets serve the section upon which are being erected the 36 semi-detached brick houses comprising the first unit of the housing program. Water is obtained by tapping the 8-ft. power pipe line, whence it flows through cast-iron piping into the suction well at the pumping station.



PLAN OF THAT PORTION OF THE TOWN THAT IS NOW UNDER CONSTRUCTION, SHOWING SEWERS

An electrically-driven pump (with a gasoline-engine-driven pump as a standby) will supply the required pressure. Eight-inch and six-inch cast-iron pipe are being laid on these streets, together with necessary hydrants, valves, tees, bends, etc.

Provision has been made for future extensions in any direction required by growth of the population.

Excavation for water and sewer pipe, which are being laid in the same trench, was through a heavy boulder soil, and in many cases solid rock was encountered, necessitating almost constant use of explosives.

The overall difference in elevation between the pumping station and the end of the first section, a distance of about 1,200 ft., is 50 ft. which gives an average grade of 4.2%. Future extensions will cover, possibly, the remaining sections of bench land leading toward the power dam at Lumsden's mill. The pumping station, when completed, will house a small, modern fire station, a filtration unit, suction well and water works equipment.

The sewer pipe commences at the pumping station (the highest point on the system at present), where a 10-in. tile

GORDON CREEK—ONE OF THE FALLS IN THE TOWNSITE OF TIMISKAMING

pipe has been laid. At the intersection of Hill and Kipawa roads, the diameter is increased to 24 ins. and the pipe continues along Hill Rd. to the centre line intersection with Gordon St., at which point an overflow chamber and manhole has been constructed. The overflow will empty over the nearby high bank into Gordon creek. The normal flow will continue down Gordon St. and at Mill Rd. will intersect the main line along Kipawa Rd. From the intersection, the sewer continues about 1,530 ft., ranging from 8 ins. to 24 ins. in diameter, all constructed in vitrified tile. The remaining 309 ft. to Gordon creek is a 24-in. creosoted continuous wood-stave pipe, with outfall at Gordon creek. Suitable concrete manholes, catch basins and stubs for future extensions have been liberally provided.

Turbine Runner Develops Crack

Water was turned into the 8-ft. power pipe, forebay and penstock August 30th, 1919. The installation tested perfectly

with the exception of the runner of the hydraulic turbine. It is said that the runner functioned for only a very short time, when it jammed at full gate opening. Upon examination it was found that the runner had developed a crack from the shaft both ways to the vanes. Fortunately a spare runner had arrived the same day and is now being installed, so it is expected that power will soon be available.

By the end of this month the barking house will be able to handle logs and to prepare a stock for storage at the piling ground. Work is being carried on day and night on some portions of the undertaking, in an effort to produce pulp before December 1st, 1919.

Future extensions to the main mill buildings will be facilitated by the fact that the wall at one end of each structure is merely a wooden curtain wall.

Personnel

The consulting engineer for the Kipawa Co., Ltd., is Hardy S. Ferguson, of New York City, who is represented on the ground by B. T. Weston. C. B. Thorne, chief engineer and technical manager of manufacture of the Riordan Pulp and Paper Co., Ltd., is in active control of the work at Timiskaming. W. L. Ketchen is resident engineer and local manager, with F. O. White as his chief assistant. Allan K. Grimmer is town engineer. The G. A. Fuller Co., of Montreal, are the chief contractors, constructing the mill, with the exception of the acid towers and acid tanks, power house and dam. The Dickie Construction Co., of Toronto, are erecting the houses. McAuslan & Anderson, of North Bay, Ont., are contractors for the sewers and water mains, tracks in the piling ground, outside piping in mill yard, superstructure of bridge crossing Gordon creek, and screen house on 4-ft. pipe line. The Sherwood Construction Co., of Toronto, are constructing the tracks leading to the coal and sulphur storage, which involves considerable rock cut and fill, and also installing the fire protection in the piling ground. Among the other contractors are the Stebbins Engineering Co., Philadelphia, acid towers; Danforth Co., Buffalo, inside piping; Dominion Bridge Co., Montreal, combined railway and highway bridge crossing Gordon creek, and the coal and the chip conveyors; Pacific Coast Pipe Co., Vancouver, both of the wood-stave pipe lines; Rensselaer Valve Co., Troy, N.Y., and Chapman Valve Mfg. Co., Indian Orchard, Mass., gate valves and sluice gates; I. P. Morris Co., Philadelphia, hydraulic turbine; Canadian General Electric Co., Toronto, and Canadian Westinghouse Co., Hamilton, electrical equipment; Herbert Morris Crane & Hoist Co., Niagara Falls, Ont., crane for power house and chain hoists.

Undeveloped Water Powers of New Brunswick

List of Possible Sites Totals 23,000 H.P. (24-Hour Power), Not Including the Grand Falls of the St. John and Nepisguit Rivers—Paper Read Last Week at the Engineering Institute's Fifth Professional Meeting

By C. O. FOSS, M.E.I.C.
Chairman, New Brunswick Water Powers Commission

LAWS governing hydrostatics and hydraulics are so simple that the way-faring may readily understand them, yet I think I may safely say that there are no other natural laws so little understood even by people of high intelligence. There is no engine of equal power which is so simple of construction and installation, so uniformly sure in action, and subject to so little wear and tear and depreciation, as the modern up-to-date hydro-turbine. I need not say that there is nothing miraculous about water power; and that in a comparison of water with other methods of power generation, we may easily make the mistake of spending so much money in the purchase, development and transmission of hydraulic power that the output may cost more than power generated in some other way, especially when the consumption is small and limited. However, these exceptions only serve to prove the very general rule that hydro power is cheaper, surer and more flexible than any other form of power that can be developed in considerable units.

As regards water power possibilities in New Brunswick, it has been considered by the people generally that there are no power possibilities of any value outside of the Grand Falls of the St. John, and a very moderate possibility at the Grand Falls of the Nepisguit, and this opinion has been strengthened by statements to that effect by parties who are supposed to be authorities upon the subject.

Grand Falls Too Remote

If this were true, the distribution of hydro-electric power in centres of population would be well nigh hopeless, for the cost of developing the Grand Falls of the St. John would be so great, and its location is so remote from the centres of population, with the market at present in sight so limited, that the interest and overhead would make the cost greater than power generated by other methods.

To make these powers commercially possible of development and use, the output must be used at or near the site in the manufacture of pulp and paper, the logical large industry for this province. In the case of the Nepisguit power the Bathurst Lumber Co. are having plans prepared for the development and transmission to their pulp and saw mills in Bathurst, and the big power at the Grand Falls of the St. John will be developed in the near future for the same purpose. The parties now controlling the latter power site have a year from the close of the war to start the development, failing which the provincial authorities will take away the control and arrange for the development by other parties.

Then, having disposed of the large power possibilities at the two grand falls, the question naturally occurs: "Where is power to be found for distribution and use in the centres of population?"

For Distribution to Municipalities

The centres of population requiring, and not at present supplied with, hydro-electric power, are three:—

First, Fredericton and vicinity; second, St. John and vicinity; third, the towns on the north shore from Chatham to Campbellton.

Moncton and vicinity has cheap power generated from natural gas.

St. Stephen has hydro-electric from the St. Croix.

Edmundston has a municipal plant on Green river. The Frasers have a development on the Madawaska for use in the pulp mill they have lately constructed. The capacity of this site may be considerably increased by storage on the Temiscouata, and they will be able to get any additional power they may need, when they enlarge their plant, from Grand Falls when that is developed.

Woodstock also has a good hydro plant.

Taking the requirement of Fredericton:—

There are two streams falling into the St. John north of Fredericton, the Pokiok and Shogomoc, 37 and 40 miles, respectively, following the highway which parallels the river, and 30 and 33 miles in an air line.

These streams each drain about 50,000 acres. The Shogomoc falls 300 ft. in the last two miles, and the Pokiok falls 200 ft. in 1½ miles and 100 ft. more in about 500 ft.

Both these streams have excellent opportunities for storage, as they drain a country which is comparatively flat to a point about 2 miles from the St. John river. In other

words, the St. John has eroded a valley 300 to 350 ft. deep, and on this flat country there is opportunity for storing large quantities of water by the building of comparatively inexpensive dams.

These two streams, if fully developed, with all possible storage provided, will yield at least 7,000 h.p. (24-hr. power), or 14,000 h.p. (12-hr. power); or assuming that the working day of the future will be 8 hours, then 20,000 h.p. if the pondage at the different plants be sufficient to take care of the fluctuations.

The plan is to develop a small unit on the lower 100-ft. drop of the Pokiok, protected by the storage which is already provided by the existing dam at the outlet of Lake George. This will give power enough to cover the present requirements of Fredericton, with quite a margin for increase of requirement. When more power is demanded, the first unit can be more than doubled by building a new storage dam about 4½ miles from the St. John. When this is outgrown, the 200-ft. fall can be developed; and when that has been absorbed, the Shogomoc can be developed. This should put Fredericton on the map as a manufacturing centre just as it already is a railway centre.

St. John's Hydro-Electric Possibilities

The second and largest centre of population requiring hydro power is St. John. All the power generated in St. John is by coal, and the New Brunswick Power Co. had to be given a very substantial increase in its rates to meet the greatly increased cost of coal and labor. They have been investigating possible water power for some time and now that the war is over they will have to go ahead with the development very soon.

The Lepreaux river empties into the Bay of Fundy about 20 miles from St. John. The drainage is about the same as the Pokiok or Shogomoc, but the run-off is nearly twice as much. We have three years' continuous run-off records, and we are greatly puzzled to account for the phenomenal run-off, being 133% of the total rainfall recorded in St. John.

The engineer who installed the gauge and took the first two years' records, explained the phenomenal run-off by assuming that the stream is receiving a large amount of subterranean drainage from the watershed of an adjoining stream, but we, having taken several checks of the run-off of this stream find the same phenomenal run-off, which proves conclusively that there must be a much larger rainfall on the watersheds of these streams than there is in St. John, only a distance of a few miles away. There are three power sites on the Lepreaux, two of 90 ft. fall and one of 64 ft., and having in mind the very great run-off of this stream, these three sites will produce at least three times the amount of power now used by the New Brunswick Power Co.

There is one power site known as big falls which can be made to generate 40% more power than they used last year. When St. John and vicinity has absorbed and put to use the 5,000 to 6,000 h.p. that can be developed on the Lepreaux, the Maguadavic, 20 miles further away, can be made to produce as much more. There is no reason apparent why the development of this power should not be put in hand in the near future.

Conditions Along North Shore

The third district where hydro power is required is along the North Shore. Bathurst alone has a small and very indifferently developed and distributed system of hydro-electric power.

Campbellton and Dalhousie drive their plants with gas engines, using gas produced from anthracite coal, and the cost of that makes their power very expensive.

Newcastle uses steam at big expense, and Chatham uses oil engines.

In addition to the requirements of these several towns, the Dominion pulp mill at Chatham requires some 400 or 500 h.p.

The Tete-a-gouche river, which enters Bathurst harbor a little north of the town, drains about 100,000 acres and has an ideal opportunity for very large storage. About 8 miles above its mouth, it enters a deep and narrow gorge of nearly perpendicular rock walls; the fall through this gorge admits of four power sites, each created by a dam built to the top of the walls and flowing the water back to the next dam up the stream. At the first or upper site, a dam 70 ft. high will give a head of 105 ft., there being a sheer fall of 35 ft. in the flow of the gorge. It will flow the water back for about 4½ miles. At the second site a dam can be built to a height of 130 ft.; the third, 65 ft.; and the fourth 35 ft.; or a total of 335 ft. These four sites will put out 6,000 h.p. (24-hr. power), or 18,000 h.p. (8-hr. power).

So it will be noted that while it was represented to the provincial authorities only a few years ago that there is no water power in New Brunswick aside from Grand Falls, we have already been able to locate and fairly well prove (apart from Grand Falls) the existence of 23,000 h.p. (24-hr. power), or nearly 70,000 h.p. (8-hr. power), which if all put to work would produce a big change of conditions in this province.

This commission has only been in existence for a little over a year, and is composed of three men busy with their regular work and so unable to give any considerable amount of time to the matter. Our people in the Maritime Provinces are surely if slowly awakening to the fact that we may overcome to a considerable extent the handicap which the upper provinces hold over us in manufacturing, due to their enormous water powers, by developing what we have discovered and looking for more.

THE BEAR RIVER BRIDGE*

By A. T. Macdonald, A.M.E.I.C.

PRIOR to 1912, the Bear river was crossed by the Dominion Atlantic Railway by a bridge consisting of about 750 ft. of wooden trestle on pile bents and five-Howe truss spans, 150 ft. long, on concrete piers with pile foundation, the piles being cut off about 2 ft. above the original bed of the river. This bridge was used for upwards of 25 years, but the piers were disintegrating rapidly between low and high water marks from the action of the river ice, and were also gradually moving downstream.

This bridge was what one might call "ripe," and certain tired souls had been known to leave the train at Deep Brook and drive by road to Bear river station, or Digby, continuing their journey the next day, in order to avoid crossing the bridge. These people, no doubt, exaggerated the state of affairs, but their nerves were not equal to the strain of travelling over 1,600 ft. of bridge at the rate of two miles an hour.

Our first work there was to make the old bridge safe for traffic until it could be replaced by the new one. This in itself was a very costly proceeding. A double row of piles were driven first, clear of the footings of each pier, and framed bents of 12 by 12-in. spruce erected on these and braced to form a tower. The bottom chord of the truss was given a bearing on this tower about 10 ft. away from the end of the truss, which was reinforced to suit this new bearing.

In this way the old piers, which were increasing their downstream movement, were largely relieved of their loads. The pier supporting the swing span slid downstream to such an extent, 10½ ins. if I remember rightly, that it became impossible to operate it. This necessitated another opening to permit vessels to pass.

Towers on pile bents were therefore erected to support a 40 ft. plate girder about 200 ft. east of the existing swing span, and when everything was in readiness, an opening was cut in the bridge and the girders dropped into position. With the aid of the Dominion Bridge Co.'s derrick car, this was accomplished without any interruption to train traffic.

---

*Paper read at the fifth professional meeting of the Engineering Institute of Canada, September 10th-12th, St. John, N.B.

This span was operated as a lift span whenever the occasion arose, the derrick car furnishing the power. The clearance for vessels going through this opening was just about the minimum, and called for expert seamanship on the part of the skippers. On one occasion a 400-ton schooner frightened everyone badly. Part of her rigging fouled the deck of the bridge, and only some very lively play with axes and prompt action by the tug, saved a very nasty situation.

Construction of a new bridge 50 ft. downstream and parallel to the old one was begun in June, 1912, and completed in June, 1914. The design, starting from the west end, called D. T. swing span, one 150-ft. D. P. G., one 100-ft. D. P. G.; one 156-ft. D. P. G.; one 144-ft. D. T. swing span; three 156-ft. D. P. G.; six 100-ft. D. P. G.; and one 85-ft. D. P. G.; the total weight, 2,500,000 lbs. of steel. These spans are carried on concrete piers on pile foundation, with the exception of piers 3, 4 and 5, which rest on a bed of coarse gravel and boulders.

Proximity of Old Bridge

The proximity of the old bridge to the proposed work provided another reason for the expenditure of money to strengthen its foundations. With a distance of only 50 ft. between lines, the noses of corresponding piers on the two bridges lay side by side, and as dredging proceeded for the new pier, in some cases being carried below the points of the piles in the old, the tendency was for the old pier to slide bodily into the excavation. Therefore the work had to be carried on with the greatest care and divers were freely employed to keep the old foundations under close observation. Of course the old bridge in many ways helped in the construction, the contractors being able to utilize it for the running of water lines and trolley lines for conveying materials, etc., and the engineering party for laying out the work and as a ready means of communication from shore to shore. But it was not a blessing, as the cofferdams were on several occasions hung up by old timber and piles.

Layout of Work

From pier 8 to the west abutment, the bridge is on a 6 deg. 10 min. curve to the left, with a central angle of 59 degs. 20 mins. A base line was carefully run over the centre line of the old bridge, and permanent hubs set on each bank, well clear of the work, from which the bridge tangent was located by off-setting 50 ft., and marked by permanent hubs which were used for giving the centre line of all piers on tangent. The transverse centre line of these piers were given from points on the deck of the old bridge. Owing to the movement of the deck, as mentioned above, these points had to be located anew for each day that it was necessary to use them. In order to eliminate as much as possible any chance of error in locating the piers on the curve, it was decided to determine the exact geometric centre of the curve and erect there a sight which would be visible at all stages of the tide. The transverse centres of the piers, being on radial lines, could then be located from hubs on the semi-tangent, using the centre of the curve as a foresight.

Accordingly the P. I. of the curve was found, and as it came on the beach at high water mark, a concrete pedestal 18 by 18 ins. and 2 ft. high was put in on pieces of 4 by 4-in., 8 ft. long, as piles, and on this the P. I. (hub A) was definitely set after repeated checking.

To establish the centre of the curve was more difficult, as the water only left it for about two hours each day. With the transit on A and backsighting on T on the west end of the bridge tangent, an angle of 60 degs. 20 mins. was laid off, and the point of intersection found with a line at right angles to the tangent of the curve at the E. C. Around this point a rock-filled crib 6 ft. square and 4 ft. high was built, and a 2 in. pipe, 24 ft. long, was securely guyed there. (Hub C).

As a check, the calculated distance from P to C was measured on the ground with 100 ft. steel tape over stakes driven to the same elevation and 100 ft. apart. The distances along the semi-tangent from P, where the radial lines for each pier intersected, were then calculated and hubs set.

The distances along the radial line from the hubs to the curve were also calculated and recorded for use when required. A hub was put in at M, the mid-point of the curve, from which the angles of the centre of each pier could be turned as a check on the above method. All measurements were made with a 100-ft. steel tape and corrections made for temperature.

Foundations

The west abutment and piers 1 and 2 were built on solid rock, and the concrete poured in the dry, no pumping being necessary. The foundation of the east abutment is on sand and gravel. The excavation for this was taken down 6 ft. below original ground and piles driven to refusal at a penetration averaging 18 ft.

Piers 12 to 14 were on typical Bay of Fundy mud and dry at low water. Cofferdams of 10 by 10 in. hemlock were built in place and sunk as the excavation progressed, being loaded with old rails to a depth of 18 ft., and piling driven. The penetration averaged 25 ft., the penetration under the last blow being from ½ in. to ¾ in., a 2,400-lb. hammer being used, with a fall of 25 ft. These cofferdams were pumped out and the piling cut off 2 ft. above the bottom and the concrete poured in the dry.

The foundations of piers 9 to 11 inclusive were built in the same manner, but the penetration and number of the piles used increased as they approached mid-stream.

In pier 8 the cofferdam was 21.7 ft. deep and the average penetration of the piles 58 ft. The piles, about 90 in number, were cut off under water and the concrete deposited with a bottom dumping bucket; the bottom of this pier covers an area of 749 sq. ft. and there are 451 cu. yds. of concrete in the footing course. In all the piers the footing course is carried about 4 ft. above low water. Between low water and extremely high water the concrete is sheathed with 4 by 6-in. southern pine, with ½-in. iron plates 2 ft. wide on the angles, attached by galvanized iron bolts 15½ ins. long. All concrete below high water mark is 1:2:4: mixture; above 1:3:6.

The remaining piers, 3 to 7 inclusive, were a somewhat different proposition. At extreme low water the depth of water varied from 20 to 27 ft., and with a rise of the tide of 28 ft., this meant a depth of 55 ft. at high water for pier 3. Borings showed for piers 3, 4 and 5, a belt of fine sand about 8 ft. thick, followed by 8-ft. of mud and then 5 ft. of gravel. At pier 6, 12 ft. of mud, 5 ft. of sand and 60 ft. of mud.

The borings were taken after the work of construction had begun and were very hurried and the information obtained not very dependable. They were taken from a platform in some cases, or from a scow moored over the site of the pier. A 3-in. casing pipe with a 1-in. water pipe attached to a force pump working inside of it, to which the bit was attached, was driven down and the washings examined. A diamond drill was used to penetrate the gravel.

No Solid Rock Encountered

At pier 7 a penetration of about 90 ft. was obtained, at which depth solid rock was reported. The platform from which the borings were taken had to be above high water mark so that the work might go on continuously; so after penetrating the overlying mud there would be about 70 ft. of casing pipe when the gravel was reached. When the inner pipe was raised and allowed to drop on this compact mass of gravel, it bounced up again, giving the impression that solid rock had been encountered. This idea was strengthened when the drilling made no further progress until the diamond was put on. I may say here that no solid rock was encountered at any of these piers when the work was completed.

It was finally decided to sink foundations for piers 3, 4 and 5 down to the gravel, or about 20 ft. of excavation by open dredging. Pier 3 was started first. A double wall cofferdam was constructed with a space of 4 ft. between the walls. The inner wall stopped about 12-ft. short of the outer and they were connected by a solid floor of 10 by 10 in. hemlock, forming a cutting edge. Projecting below this was about 16 ins. of ½-in. steel plate. The cofferdam, about 30 ft. high, was floated into position, the space between the walls filled with concrete, and old rails piled on. Dredging was

(Concluded on page 320)

STREAM FLOW AND PERCOLATION WATER

By Samuel Hall
Assistant Water Engineer, Belfast

(Continued from last week's issue)

LET us now assume that before and after a particular rainfall the stream flow curve has assumed the basic curve form, and at particular times before and after the peak the rate of 2 M.G. per day is recorded; the gain is the total discharge between those two times, because the available amount of percolation water, as indicated by the basic curve, was the same at both times; thus the benefit accruing from a particular rainfall is measured. In this case, should the stream flow curve assume the basic curve form, but not continue so far as to show the rate of 2 M.G., but only, say, 4 M.G. per day, the basic curve can be applied to the flow curve to continue the latter to the time at which the rate of 2 M.G. per day is shown. Then the total discharge, as shown by the flow curve and its continuation, between the two times represents the amount of gain.

Supply and Discharge

This case is illustrated by Fig. 5, which shows an inserted curve EF, which is a reproduction of a part of the basic curve. The time J is fixed by the rate IJ, which is the same as GH. A, B and C show the total gain due to the particular rainfall. A is the estimated surface run-off, whilst B and C show the gain of percolation water. The curve at G must be of basic form, otherwise the principles are not applicable to this case. It was not necessary to draw the portion C, as its equivalent was measurable between ordinates of the basic curve, in this case representing 4 and 2 M.G. per day, but it suffices to illustrate plainly how much more percolation water was in store at the time K than at the time H, and shows what might be called the "correction" for percolation storage. It is suggested that this correction be made in figures representing calculated evaporation loss; and as in cases where these figures are taken over a period the correction might be equivalent to two inches of rainfall, it is plain that uncorrected figures may be inaccurate. Were the basic curve only approximately obtained, it would be of some value for making this correction. The basic curve serves to illustrate the fact that over a period when percolation supply becomes reduced, "depletion" of percolation storage takes place, and this will continue until the average rate of supply and the average discharge are roughly balanced, though neither is actually constant. Conversely, when percolation supply over a period becomes increased, the "filling up" of percolation storage takes place before supply and discharge roughly balance. From another point of view, it might be seen that the average rate of discharge does not immediately change to equal an average rate of supply, but the difference goes to; or is taken from, storage, until the surface of saturation is at such a level that average supply and discharge are about balanced; thus a year's minimum can only occur after a period of small supplies, and a year's maximum only after a period of large supplies.

Maintaining Constant Supply

It occurred to the author originally that if one could determine the available percolation water stored in a drainage area at the end of a winter period, there would be something of value in estimating the amount of artificial storage required to maintain a constant supply, because with a greater amount of natural storage less artificial storage would apparently be necessary. The available percolation storage can be ascertained with the assistance of a basic curve, no doubt in many cases within near limits; yet the author thinks this figure would be of doubtful value, for it is obvious that before percolation discharge can become equal to its average rate, supplies from subsequent rainfall must first replenish the depleted percolation storage according to the amount which has been temporarily available from that source. And for the same reason it is doubtful whether the figure of minimum rate of flow is of much value where a large proportion of the mean flow is required for a constant supply.

The author suggests another use for the basic curve in which it might be of more value. As evaporation during the winter is small and the gains from rainfall should nearly equal the rainfall, the former is the discharge, plus or minus the difference in percolation storage at the beginning and end of a test period. If the difference between the rainfall and the total gain could be accounted for by evaporation, it would be safe to presume that the drainage area was water-tight; if not, there might be proof that percolation water from outside sources was feeding the stream, or, on the other hand, indications of a serious loss of percolation water from the drainage area. In the latter case there would be warning that the installation of a dam might be unfortunate, or even disastrous. There has been sufficient evidence put forward by observers to show that the percolation drainage area is in some cases considerably different from the topographical drainage area, and to consider them as equivalent without satisfactory evidence that such was the case might be an unsound presumption.

Evaporation

The rate of evaporation from water surfaces appears to follow an ill-defined relation to the power of the sun and the duration of sunshine, whilst wind also has a slight influence; but evaporation from a drainage area is influenced by other conditions, such as the soil, percolation rate, elevation and vegetation. The most important factor other than the sun is probably the capacity of the surface soil for moisture. The power of the soil to retain water is known as capillary attraction, and it is a power which defies to some extent the force of gravity. When these conflicting forces are balanced, the amount of water retained in the soil is relatively large (no doubt often equivalent to three inches of rainfall), but very variable, according to depth and fineness, and perhaps also variable with weather conditions. The power of evaporation, due largely to the influence of the sun, appears to be a stronger force than that of the capillary attraction of the soil, for the soil is robbed of part of its moisture, and therefore makes a toll of subsequent rainfall. It is doubtful whether the soil can take its full share from a particularly heavy fall as it requires too much time to do so, and consequently part of the rainfall percolates before the soil is fully satisfied. Though this latter point remains in doubt, it is quite clear that a large part of the evaporation loss in a dry period is replaced from subsequent rainfall, and at times there is but a small balance available to supplement stream flow. In hot, dry months evaporation loss from a drainage area is smaller in the absence of rain than it would otherwise be, because the moisture is not available for evaporation. The surface soil probably draws to some extent upon the subsoil immediately below it, for even vegetation which derives supplies from some depth below the surface has at such times difficulty in maintaining life. Evaporation cannot reduce the percolation storage where the latter is in deep subsoil, but may reduce very slightly the discharge from such a source by evaporation from the stream surface.

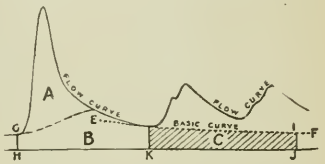


FIG. 5—FLOW AND BASIC CURVES

Figures quoted as calculated evaporation losses from drainage areas, though amended by the correction already suggested, would also include losses due to percolation water escaping from the drainage area, and for these reasons they are of doubtful value. The same remarks apply to the figures given in certain text-books to represent evaporation losses due to different forms of vegetation, as they are probably based on differences between rainfall and stream flow.

Investigations of loss by evaporation have been made by means of percolation gauges, but there does not appear to be such definite agreement between the records as might enable accurate conclusions to be deduced therefrom. It is difficult to see how soil and subsoil can be disturbed and placed in a percolation gauge in a condition equivalent to

Sept 18, 1919

that in which they originally existed, and as in the usual form of percolation gauge no surface run-off is possible, the surface water is exposed to absorption and to evaporation influences for a longer time than it would be on a steep drainage area.

Lag

This term appears to be frequently used to denote the time taken for percolation water to influence flow, and apparently is the result of investigations of the flow of the River Thames, in which there was shown to be a lag of five months between the maximum rainfall and the maximum flow, and the minimum rainfall and the minimum flow respectively. These results were obtained from average monthly figures of a period of twenty years, and it is very questionable whether it is correct to say that percolation water takes five months to reach the river. It is clear that it is not the total rainfall which constitutes flow, but only so much as is available after accounting for losses. If we were able to determine monthly evaporation losses and deduct them from the total monthly rainfall, we might make a diagram of "available rainfall," which from established facts would be relatively very small in summer, and very little different from total monthly rainfall in winter. If five months lag were allowed for, the minimum monthly flow from averages over a number of years would be expected about December, and the maximum flow about May; as this is so different from what actually occurs, it seems clear that the period of five months is incorrect, and moreover it is not even supported by actual monthly records of rainfall and flow. From monthly records of the flow of the Thames, it appears clear that there is no marked difference in point of time between the flow curve of the Thames and those of other British streams and rivers from areas in which geological conditions are a remarkable contrast. It might be reasonably expected that percolation from rain which falls near the banks of the river would feed the surface of saturation close to the river, causing some increase of flow within a very few days at most. It may be noted that percolation equivalent to one inch of rainfall might raise the surface of saturation by several feet if the fissures were of small size. The monthly records of the flow of the Thames appear to the author to show a measure of agreement with his conclusions based on observations from totally different sources; there are indications of depletion of percolation storage towards the end of the summer, and the filling up towards the end of the winter, where the maximum percolation discharge is most liable to occur in not only the Thames, but in every British stream or river.

Snow

Snow is another source of error in calculating evaporation losses from drainage areas; its presence, or any doubt as to its presence, spoils the value of comparisons of precipitation, flow and evaporation. Wherever gaugings are taken, weather conditions, and especially the existence of snow, should be recorded.

Floods

The maximum flood rate, or average rate of a short period, is of importance as the basis for determination of sizes of reservoir culverts and weirs. It is the custom to base calculations on the highest flood rate which obtained in a particular drainage area, and allow a little more to be "on the safe side." Though it may be safe, it is not a very scientific method of determination, for figures which apply to one area do not correctly apply to another. Flood discharge is chiefly surface run-off and is dependent upon a factor which varies for each area, and probably largely on intensity of rainfall, so that unless the latter has been observed in conjunction with stream flow, reliable estimates cannot be made for possible maximum rates.

Springs

The flow curve of a spring is that of percolation water alone. The author would expect a spring flow curve to have similar features to that of a stream flow curve were the "peaks" of the latter removed, and would expect the principles stated to be capable of application in most cases.

There should be little need to repeat what many observers have already stated, that to apply to any one area figures obtained from another is obviously wrong. Evaporation loss is known to vary considerably in different areas, and percolation loss cannot be determined by a mere inspection of a drainage area. Thus calculations and estimates of storage capacity, size of weir and outlet culvert, based on "rule-of-thumb" formulæ and so-called "judgment" are liable to lead, and have in some cases led, to waste of money. On the other hand, stream flow data can be had at a cost which is small in comparison with that of a water supply scheme, and which might often be saved many times over in the reduction of the size of the weir and outlet culvert. There is much need for further investigation of stream flow and evaporation, subjects which particularly concern water engineers, and which have been sadly neglected up to the present. Every drainage area has its peculiarities due to conditions therein, and all the conditions, so far as they concern water engineers, can probably be determined by investigation of the flow curve. To investigate the smaller rates of flow, it is advisable to use V notches, or a small weir in conjunction with a larger one at a higher level, also automatic recording apparatus.

TOWN-PLANNING IN WESTERN CANADA*

UNFORTUNATELY, owing to the conditions under which municipalities in Saskatchewan may borrow, it has not been practicable to put the federal housing scheme in operation in that province. Commissioner C. J. Yorath states that the chief stumbling block in western Canada for the carrying out of a housing scheme is the fact that the provincial government intends to make any loans which may be advanced for this purpose part of the municipalities' debt. In the matter of town planning and control of municipal affairs Saskatchewan has perhaps the most advanced legislation in the Dominion. The Town Planning and Rural Development Act is administered by the Department of Municipal Affairs. The comprehensive nature of this act may be gathered from the following list of regulations which have been issued under it:—

Regulations Under Saskatchewan's Act

(1) Town Planning and Rural Development (Scheme) Procedure Regulations;

(2) Town Planning and Rural Development (By-law) Procedure Regulations;

(3) Regulations applicable to new development within the jurisdiction of municipalities which have not made regulations as authorized by section five of the Town Planning and Rural Development Act, and to new development in unorganized territory;

(4) Model regulations respecting new development for adoption by urban municipalities;

(5) Model regulations respecting new development for adoption by rural municipalities.

The object of the act is effectively to control the development of cities, town and rural municipalities. The importance of this being done is fully realized in Saskatchewan. Not only has the necessary legislation been obtained, but M. B. Weeks, Director of Surveys, has been appointed Director of Town Planning, and W. A. Begg, formerly Townsite Engineer for the Department of Highways, has been appointed Town Planning Engineer. The services of both will be available to local authorities to assist and advise in the preparation of schemes and development by-laws.

Conditions Similar in Alberta

The conditions regarding the housing scheme are the same in Alberta as in Saskatchewan and, consequently, no action is being taken to put the scheme in operation.

The preparation of town planning schemes for the larger cities is proceeding.

---

THE KELLEY SYSTEM OF PAYMENT TO CONTRACTORS FOR ESTIMATING*

SINCE the "Nelson Plan" was conceived, other plans which contemplate payment for estimating have been proposed and put into operation. One of these which has received some attention, particularly in the middle west, is the so-called "Kelley Plan." This is a plan owned and controlled by "The National Contractors' Association, Inc.", a private corporation operated for profit, which acts (1) as organizer in keeping contractors in line as regards charging for estimates on a particular project, and (2) as agent for all contractors bidding on a project, in pooling and dividing the amount charged for estimating.

The plan derives its name from J. J. Kelley, president and chief stockholder of the "association." The chief elements of the plan are briefly as follows:—

Definite Schedule of Charges

A definite schedule of charges for estimating the cost of projects valued at from $2,000 to $1,000,000 or over has been established by Mr. Kelley. A contractor, party to the plan, submitting an estimate on a job, adds to his original estimate a sum equal to as many times the cost of estimating that job, as indicated by the schedule, as there are contractors party to the plan bidding on the job. Ordinarily, however, no contractor adds this amount to his bid unless all contractors bidding agree to do so. After the contract has been awarded and the job has progressed to a reasonable stage of completion, the successful contractor pays the total amount which he has added to his estimate, to the local agent of the "association." The agent divides that amount equally among the bidders, except 15%, half of which goes to the local agent and half to the "association" as commissions.

Contractors, party to the plan, must be "members" of the national "association." Membership dues were originally $10 for life; recently it has been announced that membership is free to any contractor, "general" or "sub," who will agree to adopt the schedule announced by the "association," add the proper amount to each estimate to which the plan is applied, and "divide up" with the unsuccessful bidders if he is awarded the contract.

For example:—Ten contractors, members of the "association," are bidding on a project approximating $75,000 to build. The average cost of estimating such a job has been set at $125. Each of the ten bidders then estimates the job in his own way and adds $1,250 to his bid, or ten times $125. After the contract has been awarded and the job has progressed to a reasonable stage of completion, the successful bidder pays $1,250 to the local agent of the "association." The agent gives each of the ten bidders $106.25, keeps $93.75 himself, and pays $93.75 to Mr. Kelley, of the national "association."

Results of Week's Operation

A further example of what this may amount to can be seen from the following figures, given by Mr. Kelley as the results of one week's estimating among "association" members in Toledo from March 16th, 1918, to March 23rd, 1918:—

Total received for estimating		$6,487.10
"Dues" in "National Association" for 19 members at $10	$ 190.00	
7½% commission to local agent	486.53	
7½% commission to Mr. Kelley	486.53	
85% returned to 19 members to cover cost of estimating in amounts varying from $51 to $1,095, average $280.21	$5,324.04	$6,487.10

In favor of the Kelley system are urged most of the arguments advanced in favor of any plan providing payment for estimating, especially that the owner thereby pays for estimates on his job only, that he can have just as many estimates as he is willing to pay for, and that the contractor thereby gets a fair fee for his professional services.

In contrast to the "Nelson Form" it has been urged by Mr. Kelley that his system encourages competition, which tends to reduce ultimate building costs 10%. An investigation of the operation of the system in one city in the middle west brought out the information that whereas formerly five contractors was the average bidding on work, since the Kelley system has been adopted, the average is nearer twenty.

Weakness in Kelley System

On the other hand, this very fact is urged against this particular system, and it is further stated that it encourages unscrupulous and irresponsible men to enter the field with the purpose of receiving sufficient bidding money to make a considerable profit on estimating without really contracting at all. Various elements in the Kelley system make this appear inevitable.

First, the contractor's fee for estimating is part of his bid on the job, which he controls and pays himself, rather than a separate fee paid by the owner for his services in estimating. This makes it possible for contractors to agree among themselves without the consent of the owner or the architect, to add to their bids a sum equal to the cost of estimating. So long as this is possible, there is bound to exist a tendency to do so secretly, and to "let in" on the job as many as are desired or "the traffic will bear."

With this possible, there is nothing to prevent an unscrupulous contractor from making a rough guess, high enough to insure his bid being rejected, add on the cost of estimating, and receive a share in the payment for estimating.

It is no case to state that the system is designed to be operated in co-operation with the architect and with the full approval of the owner, who would eliminate such a possibility, for, despite the good intentions of the originator and the honesty of most contractors, the actual facts show that the system falls down seriously at just this point.

Investigation in cities where the Kelley system is in operation shows that, while the number of bidders increases on some jobs because the architect is willing to pay for estimates, frequently it increases because he is unaware that he is being charged for the bids.

Accepted More Than Cost

A local agent in one city recently stated that the system did not work on a particular job where the owner took bids directly, as the contractors then had no means of finding out who was bidding in order to line everybody up, and apparently did not care to inform the owner of the plan. In another instance, where two of the announced bidders on a public contract failed to submit bids, their share of the total cost of estimating, instead of being returned to the state, was divided among the remaining bidders, showing clearly that the charge for estimating was being made without the knowledge of the engineer in charge, or else in collusion with him, to the detriment of the state. Where such secrecy is possible, excessive bidding by irresponsible contractors is also possible, and the whole system is thus brought into disrepute. This is the fundamental weakness of the Kelley system.

Other minor elements contribute to establish this fundamental weakness. According to the system, *all* or *none* of the bidders on a project must be party to the plan unless undue advantage is given those who do not include a charge for estimating in their bids. This makes it essential to employ a middleman, whose business it is to "line up" all the bidders on a project. The commission of this agent increases directly as the number of bidders increase. No matter how honest, therefore, may be the principles on which the plan is based, it is to the agent's advantage to increase the number of bidders, either as a party to the plan to charge for estimating secretly or in collusion with the owner's representative. The possibility and the actual existence of practices of this sort again bring the plan into disrepute.

*From a report of the "Committee on Methods" of the Associated General Contractors of America.

In answer to these objections, it is urged that the co-operation of the architect and the approval of the owner, if sought and gained in each instance, will remove all chance of excessive bidding. True; but it will also remove to a great extent all need for a middleman at a fancy commission. If recognition of the right to charge a fee for estimating is made by the architect or the owner, there is no reason for including the fee in the bid. If it is not included in the bid on the contract, it will not affect the total estimate, and hence it will no longer be necessary for *all* or *none* of the contractors to agree to charge for estimating. Thus will be removed the necessity for a middleman as organizer. If a fee is paid each contractor for estimating, there will be no necessity for the contractors to form a pool from which their payment may be made. Thus will be removed any necessity for a middleman as broker. Except, therefore, to educate small and irresponsible contractors in good business methods, there will be no need of special agents to make payment for estimating possible, once architects, owners and contractors see that it is desirable. Then if a system can be developed with the proper checks and balances, its adoption will be a matter of good business for all concerned.

Some General Considerations

To date, only the "Nelson Form" has proposed anything that would make the plan applicable to public work, which involves a reconciliation of the principle of free and open competition with payment for *all* estimates. If applied under the Kelley system, it must be applied secretly as noted above, or else the state would acknowledge no limit to the amount it would pay for estimates on any project. This is one of the most important and difficult problems involved in the whole situation, and one which deserves particular attention.

Another important consideration is the extension of the principle to the sub-contractors on a project where the general contractor submits the final estimate. Here again the "Nelson Form" is particularly interesting.

General contractors, in an effort to reduce their overhead costs, have been asking: "If an owner is willing to pay for plans and specifications in order that he may see how his ideas work out on paper, why should he not also pay contractors for the benefit of their experience and efforts in determining what it would cost to transfer these ideas on paper into a concrete structure?"

Since "the owner reserves the right to reject any and all bids," contractors frequently submit bids where the work does not proceed, and where no remuneration is thus paid anyone for the expense of bidding. On the other hand, while it is true that the cost of estimating is a legitimate overhead expense, it is likewise true that modern business methods teach the segregation of general overhead expense as closely as possible, and charge as many items as possible directly against the account where they belong. Applied to the expense of estimating, this means that each job should bear its full share of such cost.

With these views in mind, the "Committee on Methods" presents the following questions to general contractors and others interested, with the desire to secure as much advice as possible in formulating their conclusions on this problem:—

Questionnaire

1. Is estimating a service for which a fee should be charged, regardless of who gets the contract?

2. Is it fair to have owners of jobs undertaken pay costs of estimate (a) on projects which are not constructed, or (b) on jobs that his successful contractor has figured for other owners?

3. If selected architects are each paid for architectural competition, would a similar plan work for payment of bidding by selected contractors?

4. If this plan is not universally adopted, will not architects select contractors who do not endorse it to save these bidding fees, and thus possibly eliminate the chances of the latter on such work?

5. Should payments for bidding be based on the lowest bid submitted if work is not awarded; on the accepted bid if awarded; or on what basis?

6. If payment for bidding is appropriate and possible for building work, is it also feasible for railroad work or industrial work let on the unit price basis?

7. Should bids submitted be so itemized as to permit the owners to trade on same to competitors, and thus take possible undue advantage?

8. How many alternates should be included in bids submitted under a plan of payment for estimating?

9. Should bids be opened publicly?

10. Should payments for bidding be made only when all bids are rejected?

11. Should not cubic feet and square feet estimates be included for payment, as competitors otherwise might work out detailed estimates first and then convert same into above units?

12. What provision should be made for re-figuring altered plans?

13. How will each contractor know that another contractor is charging and insisting upon payment of his fee? Is it essential?

14. If this plan is proper for general contractors, shall general contractors extend the same practice to their sub-contractors? How?

15. Will publication of a plan in current technical periodicals bring satisfactory answers; should the letter ballot plan be adopted among responsible contractors; how should a plan be put into operation?

16. Is this plan of duplicate cost of bidding really the most economical for the industry, or should one quantity surveyor be employed by the owner and no charge for pricing such survey then be made by the contractors?

17. What plan do you believe should be advocated for the best service to the public?

PROPOSE DAM ACROSS BELLE ISLE STRAITS TO CHANGE NEWFOUNDLAND'S CLIMATE

"NEWFOUNDLAND is contemplating changing its climate," states a despatch from St. Johns, Newfoundland, recently published in a large number of daily newspapers.

"The climate of Newfoundland would be changed if a breakwater were built across the Straits of Belle Isle, between the island and the mainland, and the cold Labrador current were shunted out into the Atlantic Ocean. Such a dam is being seriously considered. It would cost an immense sum of money but engineers say it presents few difficulties.

"The Labrador current at present is the chief factor in moulding the climate, not only of Newfoundland, but of the Maritime Provinces and New England. Coming down from the Arctic Ocean it pours through the Straits of Belle Island, and, circulating around the Gulf of St. Lawrence, washes with its cold flood the coasts of Newfoundland, Quebec, New Brunswick and Nova Scotia. Then, passing through Cabot Strait, it turns south and sweeps along New England. Its strong southward flow acts as a cold wedge which pries the Gulf Stream away from all these coasts and shunts that ocean river, bearing the warmth of the tropics, off north-eastward across the ocean.

"If the Belle Isle dam is built, the Labrador current would be blocked out of the Gulf of St. Lawrence and, shearing off south-east, would miss the mainland and continue to affect only the north-eastern coast of Newfoundland. The Gulf Stream then would ease in against the continent and, flowing into the Gulf of St. Lawrence, warm all the surrounding shores and islands.

"The Gulf Stream is responsible for the mild winter climate of England and northern France. England is farther north than Newfoundland. If, after cooling off in its long passage across the northern seas, the Gulf Stream is still such a factor in tempering England's climate, it would have an even greater effect, it is believed, in tempering the winter climate of Eastern Canada and New England."

Operation of Slow Sand Filters at Toronto

Ten Thousand Samples Tested During Year 1918 Show 99.7% Average Reduction in B. Coli, 99.1% in Total Bacteria, and 99% in Excremental Bacteria—Pollution of Raw Water Increased 61.9% in Five Years Judged by B. Coli Tests

By NORMAN J. HOWARD

Bacteriologist-in-Charge, Filtration Plant Laboratory, Toronto

THE water supply for the city of Toronto is drawn out of Lake Ontario, the intakes being situated a little more than 2,000 feet due south of the plant. Filtration is effected by means of two modern installations, one being a mechanical plant of the drifting sand type, and the other a slow sand system. As the mechanical plant is being made the subject of a special report, it is proposed to deal only with the slow sand system for the period of twelve months ending December, 1918.

Out of 15,880 samples examined in the laboratory, either chemically, physically, microscopically or bacteriologically, some 10,000 were from the slow sand system.

Bacteriological Results

Tests for the enumeration of bacteria growing on agar and rebipelagar at blood temperature, and for the isolation of the colon bacillus were made on the raw and filtered water throughout the year. The average number of bacteria per c.c. growing on nutrient agar for twenty-four hours at blood temperature was 356.3 in the raw water and 2.2 in the filtered water, a reduction of 99.1 per cent. Excremental bacteria growing under the same conditions showed that the raw water contained 26.5 and the filtered water 0.25 per c.c., respectively, giving a reduction of 99 per cent. The media used in test was neutral red, lactose bile-salt, peptone agar,

TABLE A

Number of Examinations Made During the Year

" " " 1915	10,292
" " " 1916	12,076
" " " 1917	15,041

as used by Dr. A. C. Houston, of the Metropolitan Water Board, London, Eng. For the isolation of the colon bacillus, lactose ox gall was used. The raw water showed the colon bacillus to be present in one cubic centimetre on 121 days (39.9 per cent.). The average indicated number of B. Coli present in the raw water was 11.36 per c.c., whilst the filtered water contained .027 per c.c. The total percentage removal of the colon bacillus in the filtered water was 99.7. Reference to table D will show the complete figures covering the colon tests for the past six years.

Physical examination of the water was made daily, and showed that, whilst the turbidity varied considerably in the raw water, ranging between 1 to 160 parts per million, the filtered water was at all times free from turbidity, the effluent being clear, bright and sparkling. The microscopical examination was not carried out as frequently or as thoroughly as in previous years, due to the extra laboratory work involved by the new mechanical plant. Nevertheless, the observations made at the different seasons of the year were extremely valuable, and often threw light on the fluctuation in the loss of head of the filters, which otherwise would have been difficult to understand.

Amongst the many types noted were the diatoms cymbella, cocconeis, navicula gracilis, stauroneis, epithemia,

himantidium, asterionella, synedra, fragilaria, diatoma, tabellaria, nitzschia sigmoida and longissima, melosira, cyclotella, stephanodiscus, the cyanophyceae microcystis, coelosphaerium, anabaena, the chlorophyceae palmella, tetraspora, scenedsmus, hydrodicton, sorastrum, volvox, ulothrix, the protozoa actinophrys, uroglena, dinobryon, ceratium, vorticella, codonella, coleps, and several types of rotifera, crustacea, and infusoria. There were many other varieties which were not identified. Many of the above mentioned when present are known to be objectionable on account of their imparting a taste or smell to the water. During the summer months, when the water was warm, particularly during August and September, a faint taste appeared to be present in the raw water. The filtered water was practically free from organisms; occasionally there was a trace of amorphous matter, but the taste previously mentioned, whilst considerably lessened, was not completely eliminated. It is doubtful if the taste was noticed by the consumer.

Chemical Examination

Considerable time was devoted to the chemical examination of the raw and filtered water. The test for the determination of ammoniacal nitrogen is practically the only known test for ascertaining rapidly the condition of the raw water. On many occasions this information was most useful in the operation of the filters. The general reduction of the organic matter in the filtered water was satisfactory, the free and albuminoid nitrogen and the oxygen consumed showing substantial reductions. The nitrates increased, pointing to oxidation caused by nitrifying bacteria on the surface of the filters. A further increase in the chlorides cannot be regarded as satisfactory, and is another indication of the degree of pollution that is yearly increasing.

The rate of filtration for the year was 3.27 million Imperial gallons per acre per day, this being slightly lower than in the previous year. The total amount of water filtered was 11,470 million Imperial gallons. In the yearly report for 1916 special reference was made to the quality of the sand, particularly as regards the effective size and the uniformity coefficient. At that time the portable sand washer was being used in the summer months. This practice was discontinued and the washer is now used only during the winter months. The quality of the sand greatly improved during 1918 and is now in good condition.

TABLE C

Excremental bacteria growing on Bile-Salt Agar (Rebipelagar) at 37-39 deg. C., 24 hours incubation, showing monthly maximum, minimum and average number per c.c. in raw and filtered water; yearly average number per c.c. in raw and filtered water, and the total percentage reduction in filtered water for the year.

(4) The total percentage of samples showing B. Coli in one c.c. was 39.9 in the raw water and 0.66 in the filtered water.

(5) The average indicated number of B. Coli present per 100 c.c. of water examined was 1,136 in the raw water and 2.7 in the filtered water, showing a total reduction of 99.7%.

(6) Pollution of the raw water as judged by the B. Coli test has increased by 61.9% since 1913.

(7) The highest temperature recorded in the water was 64 degs. F. and the lowest 33.9 degs. F.

(8) The highest degree of turbidity occurring in the raw water was 160 p.p.m., whilst the lowest was 1. The filtered water was free from turbidity throughout the year.

(9) The chlorides in the raw water were 8.2 p.p.m. in 1913, whilst in 1918, the figures had increased to 9.89 p.p.m.

(10) The total number of filters cleaned during the year was 181.

(11) The average rate of filtration was 3.27 million Imperial gallons per acre per day.

TABLE E

Average Monthly Turbidities, Showing Maximum and Minimum Figures

Month	Raw Water			Filtered Water		
	Maximum	Minimum	Average	Maximum	Minimum	Average
January	24	1	4.0	0.5	0.5	0.5
February	39	1	4.0	0.5	0.5	0.5
March	61	1	8.3	0.5	0.5	0.5
April	160	1	26.5	0.5	0.5	0.5
May	7	1	2.0	0.5	0.5	0.5
June	7	1	1.7	0.5	0.5	0.5
July	3	1	1.6	0.5	0.5	0.5
August	8	1	1.8	0.5	0.5	0.5
September	14	1	2.9	0.5	0.5	0.5
October	7	1	1.6	0.5	0.5	0.5
November	12	1	1.9	0.5	0.5	0.5
December	65	1	18.7	0.5	0.5	0.5

(12) The average amount of water filtered was 31.42 million Imperial gallons, or 50% of the average amount of water daily consumed.

(13) *The maximum and minimum consumption daily during the year was 77.49 and 45.61 million Imperial gallons, respectively, whilst the average daily consumption was 62.72 million Imperial gallons.

(14) *The average daily consumption per capita was 128 Imperial gallons.

Conclusions

For several years past attention has been directed to the continual deterioration in the quality of the raw water. Observations were based upon the percentage number of days in the year that the raw water contained the typical colon bacillus in one cubic centimetre of water examined. The figures for the past six years which read as follows: 1913, 24.6%; 1914, 30.7%; 1915, 31.9%; 1916, 35.8%; 1917, 32.2%; 1918, 39.9%, show conclusively that the raw water is becoming impurer. The slight reduction in 1917 was due to the more favorable weather rather than to any improvement in the quality of the water.

In 1913 the colon bacillus was present on seventy-five days (24.6%) of the total number of days upon which examination of the raw water was made. This figure had increased in 1918 to 121 days (39.9%). From the figures submitted it will be seen that the pollution in the raw water was progressive in character, and that the actual percentage increase in the number of days upon which the water was seriously polluted had increased 61.9% in six years. The normal increase in population and the consequent discharge of sewage into the lake may have been the principal rea-

TABLE F

*Figures kindly supplied by Department of Works.

son for this. This applies not only to Toronto, but to the many cities, towns and municipalities in the vicinity which are daily discharging enormous quantities of sewage into the lake. With the exception of the city of Toronto, little attempt is being made to treat the effluents so as to render them innocuous. As far back as 1912 (city engineer's report) it was clearly shown that the water of Lake Ontario was polluted by currents some seven miles out from the intakes. When these conditions are taken into consideration, together with the various pollutions arising from marine traffic, dredging operations, spring freshets and the frequent pollution following summer storm floods, it will be seen that the contributory causes are numerous. Probably there are no cities on the great lakes where the pollution of the raw water in the immediate vicinity is not yearly increasing, regardless of the steps taken to prevent the discharge of putrescrible matter into the rivers or lakes involved, those responsible for the purification of water supplies depending upon filtration for clarification and chlorine for final sterilization.

While the occurrence of pollution in the raw water is yearly increasing, the degree of pollution is intensifying. As has been the case for several years past, the most serious pollution occurred in the summer and fall months. On forty-seven days the raw water contained the colon bacillus in 1/10th part of one cubic centimetre, on twelve occasions in 1/100th part, and on two occasions in 1/1000th part of one cubic centimetre. Assuming that crude sewage contains at least 100,000 B. Coli per c.c. the last two figures showed the raw water to contain a pollution equivalent to 1,000 and 10,000 parts of sewage, respectively, to each million gallons of water.

Oxygen consumed	34.4%	"
Nitrates	59.2%	Increase

Chlorides and Alkalinity showed little change.

Final Sterilization Always Necessary

The daily examination showed the raw water to be subject to a continuous and increasing degree of pollution, which condition was almost entirely controlled by the meterological conditions prevailing at the time. From this it would seem desirable that early action should be taken to treat sewage that is being discharged into the lake, so that the effluents are rendered innocuous. The remarkable figures obtained by filtration reduced very materially the degree of pollution previously mentioned as occurring in the raw water, and show that the actual results achieved by filtration alone would almost have rendered the water fit for consumption without final sterilization, but it must be remembered that a water that is initially polluted with matter of excremental origin can never be filtered so efficiently as to render it innocuous. For instance, if a water before filtration contained 5,000 bacteria per cubic centimetre and filtration removed 99.5%, there would still be twenty-five remaining, some of which might belong to the pathogenic group, which, if of a virulent nature, might be capable of causing a serious epidemic. The necessity of final sterilization then becomes apparent. Throughout the year the figures obtained by filtration showed splendid efficiencies equalled by few plants on the American continent. At present Toronto is fortunate in having a water supply that is both filtered and chlorinated. The excellent system of chlorination is directed by Col. Geo. G. Nasmith, Director of Civic Laboratories, and consequently the water as finally delivered to the consumers is splendid, being clear, bright and of high bacterial quality.

TABLE H.—FILTER OPERATION

Average Rate of Filtration for the Year.—3.27 million Imperial gallons per acre per day.
Total Amount of Water Filtered.—11,470 million Imperial gallons.
Maximum and Minimum Amount of Water Filtered in 24 hours.—Maximum, 40.04; minimum, 18.58 million Imperial gallons.
Average Amount of Water Filtered Daily.—31.42 million Imperial gallons.
Number of Filters Raked or Cleaned.—181.
Filter runs, length of runs in days completed during each month, showing maximum, minimum and average figures, and yield per run in million Imperial gallons per acre.

Month	Maximum	Minimum	Average	Yield Per Run Per Acre

December	39	2	19.4	65.04

The name of the firm of Brennan and Hollingworth, contractors, Hamilton, Ont., has been changed to the W. C. Brennan Contracting Co.

A good roads association has been organized at Chilliwack, B.C. Following are the officers: Hon. presidents, F. B. Stacey, M.P., Hon. E. D. Barrow, M.L.A., Mayor Ashwell and Reeve Evans; president, W. L. Mackin; vice-president, E. H. Barton; secretary, W. R. Theal; treasurer, G. O. Nesbitt.

The New England Water Works Association will hold its annual convention September 30th to October 3rd, inclusive, in Albany, N.Y. The preliminary program, which will be published in full next week, includes a paper by Norman J. Howard, of Toronto, on the "Operation of and Purification Effected by the New Drifting Sand Filter System at Toronto." The president of the association is S. E. Killam, superintendent of pipe lines and reservoirs of the Boston, Mass., Water Works. The secretary is Williard Kent, civil engineer, Narrangansett Pier, R.I.

The Greater Winnipeg Water Board has decided to wait until next spring before proceeding with the work of underdrainage for a section of the Shoal Lake aqueduct. It is estimated that this work will cost $330,000. It is necessitated by the alkali waters in the soil surrounding one section of the aqueduct. The proposed pipe line to Transcona will likely be built this fall, the councils of all the municipalities interested having tentatively agreed upon the extension. It is likely that the price of 2c. per 1,000 gals., which is now being charged, will be reduced to 1¼c., as the Board has recommended this reduction, claiming that it has found that the water can be sold without loss at the lower rate. All the municipalities interested have not yet agreed to the reduction, so it is being held in abeyance for the time being.

CANADIAN ENGINEERING STANDARDS ASSOCIATION

Visit from Secretary of the British Association—Appointment of Committees and Sub-Committees—Report to be Prepared on Standard National Electric Code

At a meeting of the main committee of the Canadian Engineering Standards Association, held September 8th, H. H. Vaughan presiding, the following new members were appointed:—

J. M. R. Fairbairn, nominated by the Canadian Pacific Railway; H. H. Kelley, nominated by the Grand Trunk Railway; A. F. Stewart, nominated by the Canadian National Railways; F. A. Gaby, nominated by the Hydro-Electric Power Commission of Ontario; A. A. Dion, nominated by the Canadian Electrical Association; and J. Stadler, nominated by the Canadian Pulp and Paper Association.

The lists of members for the following sectional committees were approved:—

Electrical sectional committee, Dr. L. A. Herdt, chairman.

Sectional committee on steel bridges and construction, G. H. Duggan, chairman.

Sectional committee on wire rope, Prof. H. M. Mackay, chairman.

Recommendations as to membership of the following sub-committees were received, and the committees appointed accordingly:—

Sub-committee on steel railway bridges, P. B. Motley, chairman.

Sub-committee on incandescent lamps, John Murphy, chairman.

Sub-committee on transformers, A. A. Dion, chairman.

The secretary reported the progress made with regard to various questions already under consideration, and further reported a number of requests for action on the part of the association. Several of these were approved for further enquiry and report.

The chairman welcomed C. Le Maistre, the secretary of the British Engineering Standards Association, who is now on a visit to Canada and the United States. Mr. Le Maistre described briefly the work of the B.E.S.A., and drew the attention of the committee to certain matters in which his association would welcome the assistance and co-operation of the Canadian Engineering Standards Association, referring especially to proposals which have been made with a view of obtaining some degree of Anglo-American agreement as to screw thread standards. Mr. Le Maistre further pointed out the desirability of international agreement as to rules affecting electrical appliances and fittings, particularly for interior use.

As regards the first suggestion, it was decided to appoint a sub-committee on screw-threads, with instructions to consider and report on Mr. Le Maistre's communication.

Considerable discussion took place on the question of rules for electrical appliances, and the committee agreed that the formulation of a "Canadian Electric Code" was most desirable. The committee then directed that a sub-committee should be called together to enquire and report further as to this point.

H.R.H. the Prince of Wales unveiled commemorative tablets on the Quebec bridge during his recent visit at Quebec. These tablets bear the names of the engineers chiefly responsible for the successful completion of the bridge.

Regina's Board of Trade favors the proposed pipe line from Elbow, Sask., for supplying Regina and Moose Jaw with Saskatchewan river water. A committee has been appointed to interview the provincial government.

A. C. Grant, of the Grant Construction Co., has asked Toronto's city council to excuse him from carrying out his contract to lay a concrete roadway on Keewatin Ave., North Toronto. Mr. Grant complains that he cannot obtain labor even at fifty cents an hour and carfare. He states that he also has a contract in Brampton, Ont., which he will not be able to complete this year for the same reason.

THE BEAR RIVER BRIDGE

(Continued from page 312)

then begun with an orange-peel bucket, through a well in the centre of the dam. As the cofferdam went down, it was built up to keep the top above low water level. The position of the cutting edge was determined daily by obtaining the levels of four points on the dam equidistant from the cutting edge, and the dredging was directed accordingly to keep the dam vertical.

This was quite successful until a depth of 12 ft. had been obtained, when one side of the dam got hung up on a large boulder, with the result that the dam took a list of about 15 degs. from the vertical.

Divers were then sent down to direct water jets around the obstructions and dredging was carried on the outside of the dam on the high side. Finally the dam was straightened up into its correct position at a penetration of about 28 ft. and resting on a bed of coarse gravel and boulders. The total height of the dam is 62.4 ft. containing 130,000 ft. of timber and 1,473 cu. yds. of concrete.

Pier 4, the pivot pier, was sunk in similar manner to the depth of 36 ft. and contains 175,000 ft. of timber and 19,000 cu. yds. of concrete. Pier 5 was sunk to a depth of 40 ft. and contains 142,000 ft. of timber and 1,453 cu. yds. of concrete.

Under-Water Pile Driving

At piers 6 and 7, where the boring showed a considerable depth of mud, it was decided to excavate about 15 ft. and drive piles. After the excavation was complete, there was a depth of 35 ft. of water at low water, and the under-water method of driving piles was introduced.

This method caused considerable discussion on the work, some claiming that it would develop at least 85% efficiency as compared with the ordinary method of driving piles with a drop hammer. I may here say that the average penetration with the under-water method was only about one-half of what was obtained at the same location with a lighter hammer falling through air. In the under-water method, the guide pile and hammer were handled by a stiff derrick operated by a 25 h.p., 3-drum hoist. The guide, constructed of four 3½-in. steel angles, latticed together, was 22 in. sq., inside measurement, and all rivets were sunk on the inside. It was made in 15 ft. sections, capable of being bolted together to give the required length. Lugs riveted to the top section rested on crossed timbers on the cofferdams, and the guide hung therefrom, just clear of the bottom of the excavation and over the spot where the pile was to be driven.

The pile was then inserted in the guide and allowed to drop to the bottom. With heavy piles, as much as 10 ft. penetration was obtained in some cases right at the start. The hammer weighing about 5,000 lbs., was built to give a clearance of about ¼ in. all round inside the guide, and terminated in a truncated pyramid. The hammer was lowered into the guide after the pile and driving commenced, a fall of from 12 to 15 ft. being given. The fall was thus limited, as it was found that the pile heads broomed badly.

Prevented Interruption of Work

The piles used were exceptionally good, but many of them failed to stand up under this treatment. The maximum penetration obtained was 46 ft., whilst test piles, driven from the same location from a scow with a 24,000 lb. hammer and a trolly, gave a penetration of 65 ft.

However, the big advantage of being able to drive under water was that the work could go on at all stages of the tide, and this meant that at high water the driving was being done through 70 ft. of water. The condition of the old bridge was such that anything within reason which would hasten completion of the new could not be neglected.

The length of the bridge is 1,640 ft. The total amount of concrete used was 13,000 cu. yds. The contractors for the abutment and for piers 1 and 2 and 8 to 14 inclusive were Powers & Brewer, of St. John; for piers 3 to 7 inclusive, the Foundation Co., Ltd., of Montreal. G. G. Hare was the engineer for the Dominion Atlantic Railway, and the writer was resident engineer.

EFFICIENCY, PRODUCTION AND CONSERVATION CANADA'S NEEDS OF THE HOUR

CONSERVATION of material, in order to assist in national reconstruction, must find expression in the following eight measures, says a writer in the last issue of "Conservation," the official bulletin of the Commission of Conservation:—

(1) Increase the fertility of the soil and reclaim areas not under cultivation at present.

(2) Protect our forests from fire and reforest denuded areas.

(3) Guard certain species of fish and wild life against extinction.

(4) Exploit our mines conservatively, extracting the maximum output of ore.

(5) Develop our potential resources of hydro-electric power.

(6) Organize our manufactures to secure maximum efficiency and to recover by-products.

(7) Eliminate extravagance in consumption.

(8) Find an economic use for materials now treated as refuse.

This is a succinct statement of a very comprehensive program, and one that must be followed if Canada is to hold her own in the economic struggle. The second phase of conservation necessary for efficiency during the reconstruction period, is conservation of our human resources. As pointed out by the Commission of Conservation, work under this heading must include:—

(a) Efficiency in public hygiene and sanitation.

(b) Sound town-planning schemes and improved housing.

(c) Better roads and better organization of all systems of transportation, so that products may be conveyed from producers to consumers with minimum effort and expense.

Some of this work is beyond the jurisdiction of the Commission of Conservation, but that commission is performing useful service in repeatedly calling the attention of the public to basic requirements. With the active co-operation of the newly-organized departments of Public Health and Public Highways, the good work of the Commission of Conservation will be given a great impetus.

ONTARIO HIGHWAY AWARDS RESCINDED

TWO weeks ago the Department of Public Highways of the Province of Ontario announced the award of four contracts for the construction of 50 miles of the provincial highway; yesterday the deputy minister in charge of the department rescinded the awards and stated that the contracts would not be signed. The reason given is that the lowest tenders received were 50% higher than expected.

The specifications called for bituminous construction, penetration method. The lowest bid received for any section was $32,000 a mile; for another section the lowest bid was $40,000 a mile; while for the other two sections the lowest bids ranged between those two figures. These prices were exclusive of the cost of culverts.

W. A. McLean, deputy minister of the department, declares that the work will be carried out by day labor, and that a great saving will thereby be effected. The department, says Mr. McLean, pays labor 30 to 35 cents an hour, while contractors offer 45 to 55 cents in order to persuade men to enter their employment at once. "Time is more important to the contractor than to the province," says Mr. McLean. "The contractor loses money if he cannot finish the work quickly. The province can wait and engage men from the farms whenever they are willing to work for the wages offered. The fact that the province's plant is tied up for a long period is not considered to be a serious factor, whereas a contractor must keep his plant in more or less constant use."

The fact that the awards have been rescinded does not mean that the roads will not be built, says Mr. McLean, but they will be built at a slower rate and by provincial forces, but, he prophesies, at less expense. The change in policy regarding these awards involves more than the question of day labor vs. contracts, as Mr. McLean intimates that the department may construct water-bound macadam and gravel roads at first and may not surface them in any more permanent manner for a few years. That is, cheaper roads may possibly be built with the intention of using them, after consolidation by traffic, as foundations for more expensive types of construction such as asphaltic or tar macadam or cement-concrete. Mr. McLean states that the better types of surfacing will be laid as soon as the macadam has fully settled and that meanwhile the roads will be well oiled.

FAIR PLAY FOR THE G.T.R.

AS the pioneer railroad of Canada, the Grand Trunk Railway is entitled to the benefits of arbitration in establishing a fair price for its assets and prospects. Conferences are now being held in Ottawa by the prime minister of Canada, Sir Robert Borden, and the chairman of the G.T.R. directorate, Sir Alfred Smithers, and it is thought that the result may be mutually satisfactory without recourse to either litigation or arbitration. Should unforeseen difficulties be encountered, the G.T.R. should agree to a reasonable minimum payment and the government should agree to arbitrate, as there appears to have been a difference of more than $4,000,000 per annum between the G.T.R.'s earlier claims and the rental which the government offered in the first negotiations. The old G.T.R. deserves fair play.

PERSONALS

WILLIAM GORE, consulting engineer on the staff of the John ver Mehr Engineering Co., Ltd., Toronto, has tendered his resignation to that company in order to become a member of the new consulting firm of Gore, Nasmith and Storrie. Mr. Gore was born April 13th, 1871, at King's Lynn, Norfolk, Eng., and received his preliminary education at the King's Lynn Technical School. From 1888 to 1892 he was an articled pupil at the Highgate Iron Works, King's Lynn, and for the following two years was assistant engineer at that plant. In 1893 he won the Norfolk County Council scholarship and in 1894 the Witworth Exhibition scholarship, and entered the mechanical engineering course at the Technical College of the City and Guilds Institution of London, Eng., where he graduated in 1896. For more than a year after graduation, Mr. Gore was chief draftsman of the Western Electric Co., of Woolwich. In 1897 he joined the staff of the late George F. Deacon, consulting water works engineer, and was the latter's chief assistant until 1909, when, upon Dr. Deacon's death, the business was taken over by Sir Alexander Binnie. From 1897 to 1912 Mr. Gore had experience on many large water supply, sewerage, irrigation and hydro-electric projects in various parts of the world, including Great Britain, Russia, Italy, Greece, India and Australia. During that time he designed and constructed a considerable number of masonry dams. In 1912 Mr. Gore completed the invention of what is now known as the Ransome drifting sand filter, and joined the Ransome-ver Mehr Machinery Co., of London, Eng., for the purpose of developing that system of water filtration. When tenders were called in 1913 for a new mechanical filtration plant for the city of Toronto, the London company incorporated a Canadian branch, the John ver Mehr Engineering Co., Ltd., of Toronto, and obtained the contract for the construction of a plant of 60-million Imperial gallons daily capacity. It was stipulated as part of the contract between the city and the company, that the inventor of the process would reside in Toronto during the construction of the plant and until its acceptance by the city. As a result of this contract, Mr. Gore came to Canada and devoted most of his time to the new plant at Toronto Island until its formal acceptance several months ago. During the past few years Mr. Gore, in collaboration with Mr. Storrie, also designed and constructed small filtration units for the Collingwood fisheries, the Dominion Bank building at Toronto, and the Sun Life building at Montreal. He also designed and recently completed a filtration plant of 1,728,000 Imperial gallons daily capacity for the town of Oshawa, and an effluent disposal works for the Robson tanneries at Oshawa. Under Mr. Gore's direction, the ver Mehr Co. is now constructing a small filtration plant at Rockland, Ont. Mr. Gore is a member of the Institution of Civil Engineers of Great Britain, of which he is a George Stevenson gold medallist of the year 1907. He is also a member of the Engineering Institute of Canada and of the American Water Works Association.

G. CORDON COTTRELL, general manager of the Dominion Salvage and Wrecking Co., Toronto, has resigned.

HON. ANTONIO GALIPEAULT has been "sworn in" as Minister of Public Works in the Quebec provincial cabinet.

A. S. CLARSON, who a couple of weeks ago resigned the secertaryship of the Association of Canadian Building and Construction Industries, intends to re-engage in private practice in Montreal. Mr. Clarson was formerly city engineer of Verdun, P.Q.

THEO. J. LAFRENIERE, sanitary engineer of the Quebec Provincial Board of Health, is one of the three men named by the lieutenant-governor of Quebec as members of the provincial housing commission. Mr. Lafreniere is also a professor of sanitary engineering at Ecole Polytechnique, Montreal.

D. H. SCOTT, formerly assistant chief draftsman of the Manitoba Public Works Department, has been appointed chief draftsman, succeeding the late G. H. Baird. Mr. Scott enlisted early in the war and upon his return was attached to the Hospital Commission. He returned to the provincial works department in July.

E. A. JAMES, MAJ. T. R. LOUDON and LT.-COL. C. S. L. HERTZBERG, who have been the partners in the consulting firm of James, Loudon & Hertzberg, Ltd., Toronto, have decided to dissolve partnership. Mr. James will continue the present business, probably under the firm name of E. A. James, Ltd., while Maj. Loudon, Col. Hertzberg and a well-known Montreal engineer will establish a new firm as consulting and supervising structural engineers, with offices in Toronto and Montreal.

NEW CONSULTING FIRM, GORE, NASMITH & STORRIE, TO SPECIALIZE IN PUBLIC HEALTH

ANNOUNCEMENT has been made of the organization of a new firm of consulting engineers, Gore, Nasmith & Storrie, of Toronto, who will specialize in all forms of public health engineering, including water works, sewerage, sewage disposal and bacteriological research.

The partners in the firm will be William Gore, consulting engineer of the John ver Mehr Engineering Co., Ltd, Toronto; Col. Geo. G. Nasmith, director of laboratories of the Department of Health, city of Toronto; and William Storrie, chief engineer and general manager of the John ver Mehr Engineering Co., Ltd.

Both Mr. Gore and Mr. Storrie have tendered their resignations to the ver Mehr Co., but Mr. Gore's resignation will not take effect until other arrangements have been completed by Mr. ver Mehr for the management of the latter's Toronto office. Mr. Storrie's resignation took effect at the beginning of this month. It is not expected that Col. Nasmith will sever his relations with the city of Toronto until the end of this year, and meanwhile the work of the new firm will be carried on mainly by Mr. Storrie.

A detailed record of Mr. Gore's career appears in the "Personals" column of this page.

Col. Nasmith is a graduate of the University of Toronto and has received the degrees of M.A., Ph.D., D.Sc., and D.P.H. (Doctor of Public Health), and as a result of his sanitation work at the front for the British army, he was honored two years ago with the Companionship of St. Michael and St. George. He has been director of laboratories at Toronto for the past eight years.

Mr. Storrie is a graduate of the Glasgow and West of Scotland technical college. He came to Canada in 1909 as resident engineer on the construction of the slow sand filtration plant at Toronto Island. In 1912 he was appointed in control of the water works system at Ottawa during that city's second typhoid epidemic. In 1913 he returned to Toronto to accept the position from which he has just resigned. Early in 1918, Mr. Storrie went to England to take charge of the construction of several concrete ships for which the ver Mehr Co. had Admiralty contracts, returning again to Canada about two months ago.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand or proposed, contracts awarded, changes in staffs, etc.

TENDERS PENDING

Further information may be had from the issues of *The Canadian Engineer*, to which reference is made.

BRIDGES, ROADS AND STREETS

Alvinston, Ont.—Tenders will be received until 2 p.m., September 27th, by Brooke township council for construction of repairs to 3-4 sideroad. Plans at office of clerk, lot No. 16, concession No. 9, Brooke. Commissioners, L. Lindsay, R.R. No. 2, Alvinston and C. Atkin, R.R. No. 1, Inwood.

Bowmanville, Ont.—Petitions for cement walks on George St., from Church to Pinch's Lane; Duke St., from Durham to Base Line; Ontario St., from Albert to Nelson, were granted by the town council.

Bowmanville, Ont.—Town council passed by-laws authorizing the construction of cement walks on Concession, Liberty, Queen and Scugog Sts. Town engineer, Chas. F. Gibson.

Dundas, Ont.—Contract awarded to James A. Vance and Co., of Woodstock, for the erection of a new bridge at Head St.

Islington, Ont.—Etobicoke council are calling for tenders for construction of a four-foot concrete sidewalk on Scarlett Rd., from Bridge St., northerly, 859 lin. ft.

Kingston, Ont.—Contract let to W. H. Harvey by the Department of Public Works, Ottawa, for grading and road work.

Kamloops, B.C.—City Engineer Eric T. Kingswell will report to the city council on necessary repairs to streets. Tenders will be called for the widening of Columbia St.

North Temiskaming, Que.—The Hamilton Bridge Co. have secured contract and commenced construction of steel highway bridge across the River des Quinze. Length, 600 ft., two spans of 240 ft. each and two spans of 60 ft.

Orillia, Ont.—The Grand Trunk Ry. bridge at the Narrows, near Orillia, is to be replaced by a new structure, 344 ft. long, and work has already commenced.

Orillia, Ont.—A by-law authorizing the construction of pavement on West St., from Coldwater St. to Neywash St., has been passed by the town council. Town engineer, J. S. Blickersderfer.

Oxford Centre, Ont.—Tenders will be received until September 20th, for construction of steel and concrete bridge, 22 ft. span, opposite lot No. 8, concession No. 3, East Oxford Township. Engineer, F. J. Ure, Woodstock. F. G. Jackson, clerk, East Oxford.

Revelstoke, B.C.—Construction, under contracts recently awarded by the department of public works, Victoria, B.C., to Angus McDonnell, Vancouver, B.C., has been started on the section from Revelstoke to four miles westerly, and from Arrowhead two miles toward Revelstoke. Wm. Ramsay, resident engineer.

Richmond, B.C.—Contracts have been awarded by the department of public works, Victoria, for construction of surface, 16 ft. wide, on No. 3 road, Lulu Island, as follows: To Harrison and Lamond, 12,000 sq. yds. and to M. P. Cotton Co., 12,100 sq. yds. Approximate cost, $40,000.

Riverside, Man.—The municipal council has authorized the sale of debentures amounting to $84,500 to provide for the draining, grading and gravelling of 81½ miles of roads. Town clerk, E. M. Putnam, Dunrea, Man.

Scarboro Township, Ont.—Township council proposes to open Danforth Ave., from Birchmount Ave. to Kingston Rd.

Sherbrooke, P.Q.—See item under "Sherbrooke" in "Factories and Large Buildings" section of this issue, mentioning bridges for which contracts have been recently received by the MacKinnon Steel Co., Ltd.

St. Cecile, P.Q.—Contract awarded to Louis Cosette by town council for the construction of macadam roads estimated to cost $21,825.

St. Clement, P.Q.—Municipal council has awarded contract to Achille Picard, Beauharnois, P.Q., for the construction of bituminous macadam roads estimated to cost $30,266.

St. John, N.B.—A comprehensive street paving proposition to cover a period of four years and involving the expenditure, if adopted, of from $800,000 to $1,000,000, is to be prepared by City Engineer G. N. Hatfield.

Toronto, Ont.—A deputation of ratepayers from Mount Pleasant district will request the city council to widen Mount Pleasant Rd. to 86 ft.

Toronto, Ont.—City council intends to construct asphalt pavements on St. Clair Ave. estimated to cost $129,032. City clerk, W. A. Littlejohn.

Toronto, Ont.—At a recent meeting of the Board of Control Mayor Church moved that the Assessment Commissioner, the Commissioner of Works and the Finance Commissioner report on the advisability of extending University Ave. from Queen to Front Sts.

Toronto, Ont.—Mayor Church will move for the revival of the by-law (passed in 1914 and repealed in 1917) calling for the extension of Teraulay St. by joning it up with St. Vincent, Chapel Lane, North and Ketchum Sts. to Davenport Rd. The by-law provided for the widening of these streets from College St. to Davenport Rd. to 86 ft.

Toronto, Ont.—A typographical error was made in this column in our issue of September 4th in the address of Lieut. J. G. Murphy, to whom was awarded the contract for one section of the Ontario provincial highway. Mr. Murphy's address is 84 Dominion St., Toronto, and not 28 Dominion St., as reported. Before enlisting in the army Mr. Murphy was with the Edmonton Contracting Co.

Toronto, Ont.—The recommendation of Commissioner of Works R. C. Harris for the construction of brick block and asphalt pavements from Gerrard St. to 410 ft. north of Walpole Ave. on Morley Ave. at an estimated cost of $29,148 has been approved by the works committee.

Tres Saint Sacrement, P.Q.—Parish council has awarded contract to Leger and Charleton for the construction of a macadam road to cost $9,900.

Waterloo, Ont.—Town council is considering the construction of a driveway along the park. Town clerk, James C. Haight.

Winnipeg Man.—The Good Roads Board will call for tenders for bridgework in the municipalities of Woodworth. Ritchot, De Salaberry, Elton, Daly, Mineota, Stanley and Franklin.

Winnipeg, Man.—Contracts have been awarded by the Good Roads Board as follows: Gravelling 12 mls. highway at St. Francois Xavier, to H. E. Walker, $25,000; construction of concrete bridge, municipality of Wallace, to W. F. Manser, $2,740; reinforced concrete culverts, municipality of North Norfolk, to W. Folkhammer, MacGregor, $5,250; concrete bridge, Rockwood, to Schaler Lacour, Winnipeg, $3,275; concrete culverts, Rockwood, to W. Sampson, Winnipeg, $2,425; concrete bridge, Morden, to W. J. Harris, Morden, $2,916; 4 mls. grading, municipality Richot, to A. Berriault, St. Adolphe, $4,600.

York Township, Ont.—Contract has been awarded by township council for construction of Tarvia X pavement on Westmount Ave., from north end of present part to Miller Ave., to Asphaltic Concrete Co., $3,965. Frank Barber, engineer, 40 Jarvis St., Toronto.

York Township, Ont.—Contracts have been awarded by the township council for construction of sidewalks as follows: To Angotti and Smythe, Bernice Cres., N.S., $4,725, Dennis St., N.S., $1,627.25; to National Construction Co., McRoberts St., both sides, $8,288; to Walton and Rowell, Poulton Ave., N.S., $2,900, Torrens Ave., both sides, $5,510. Rejected tenders: Angotti and Smythe, McRoberts, $10,292, Poulton Ave., $5,049.25; Sheridan Co., Bernice Cres., $6,305, Dennis, $2,435, McRoberts, $11,789.50, Torrens, $18,832.20; Johnson Co., Bernice Cres., $4,850, Dennis, $1,750, Poulton, $4,369, Torrens, $7,000; National Construction Co., Bernice, $5,425, Dennis, $2,128, Poulton, $5,846, Torrens, $7,800. Frank Barber, engineer, 40 Jarvis St., Toronto.

York Tp., Ont.—Miles of new concrete sidewalks will be laid before the coming winter. Contracts have been let for a great amount of work and tenders will be called for the rest within a few days. The programme provided for calls for over five miles of walks as follows: Torrens Ave., north side, from Don Mills Rd. to Leslie St., and on the south side, from Don Mills Rd. to Pape Ave.; Keene St., west side, from Sammon Ave. to Mortimer St.; Weston Rd., both sides, Lambton Ave. to Eglinton Ave.; Barr Ave., both sides, Weston Rd. to Brownhill Ave.; Lauder Ave., west side, Miller Ave, northerly, 401 ft.; St. John's Rd., north side, city limits to Jane; Glenholm Ave., east side, Medway to Rogers Ave.; Atlas Ave., west side, city limits to Hurstings Ave., and east side city limits to Normanna Ave.; St. Clair, north side, from city limits to Jane St.; Brownhill Ave., both sides, from Eglinton Ave. southerly 900 ft.; Bernice Cres., north side, from Eileen Ave.; Poulton Ave., north side, from Woodbine westerly 1,942 ft.; Dennis Ave., north side, Weston Rd. to Syndicate Ave.; McRoberts Ave., both sides, from city limits northerly 1,735 ft.; Pape Ave., east side, from city limits northerly 4,000 ft. Clerk, W. A. Clarke, 40 Jarvis St., Toronto.

York Tp., Ont.—Township council intends to construct a Tarvia X pavement on Millerson Ave., from Glenholme Ave. westerly to Lauder Ave., 240 ft., estimated to cost $3,000. Clerk, W. A. Clarke.

WATER, SEWAGE AND REFUSE

Alvinston, Ont.—Tenders will be received until 2 p.m., September 27th, by Brooke township council for construction of drain, concession 8-9. Commissioners, L. Lindsay, R.R. No. 2, Alvinston and C. Atkin, R. R. No. 1, Inwood, Ont.

Bowmanville, Ont.—Town council authorized Engineer Chas. F. Gibson to construct a sewer and water main on George St.

Calgary, Alta.—The Alberta government, with the aid of the Federal government, will put into effect a comprehensive irrigation scheme along lines already determined by Federal government surveys. Acreage possible to be irrigated in Alberta, 5,000,000.

Chatham, Ont.—A sewer will be constructed in Kirk St. City engineer, Mr. Adams.

Chatham, Ont.—Ratepayers will be asked to vote on by-laws providing for extension of waterworks plant, scheme for merging the water commission, extension of parks, athletic park and change of civic government to city managership.

Cobourg, Ont.—A by-law to grant the Douglas Packing Co. $5,000 towards securing an adequate supply of water for their new plant was carried by the property owners of Cobourg recently.

Halifax, N.S.—The city council will shortly call for tenders for a sewer and water pipe trench on Harvard St., and sewer and water extension on Russell St., from Agricola to Robie. A sewer is also to be laid on North Park St., from Cornwallis to Cogswell. City engineer, F. W. W. Doane.

Maidstone, Ont.—Tenders will be received until noon, September 20th, by township council, Sandwich South, for repairs to the following drains: Donovan, Sullivan creek, Sixth Concession, Twelfth Concession and South Talbot. Plans, etc., J. S. Laird, Essex, and John McAuliffe, clerk, Maidstone.

Orillia, Ont.—Town council passed a by-law to borrow $24,000 for waterworks extensions and improvements. Town engineer, J. S. Blickersderfer.

Pelee Township, Ont.—Extensive work will soon be undertaken to improve the Big Marsh drainage system. Tenders have been called and contracts will soon be awarded for dredge cutting and embankment, reinforced concrete and other work at East Side Pumping Station, furnishing and installing a new submerged centrifugal pump in the West Side Pumping Station. Engineer in charge, Alex. Baird, Leamington.

Preston, Ont.—Board of works is considering the construction of sewers from Hamilton St. North to Main St. Town engineer, C. S. Mackenzie.

Regina, Sask.—The provincial government contemplates construction of a joint water works system for the towns and cities, from Moose Jaw to Regina. Water would be obtained by diverting the flow from the South Saskatchewan river, near Elbow.

Sarnia, Ont.—City council adopted the report of the waterworks committee, recommending the purchase of a chlorinating plant for the Point Edward waterworks and a six-inch water main for Cromwell St. City engineer, J. A. Baird.

Smith's Falls, Ont.—Town council passed a by-law authorizing the issuing of debentures to raise $5,574 to extend the waterworks along Queen St., from Thurber to Carthage Sts. Town engineer, J. H. Moore.

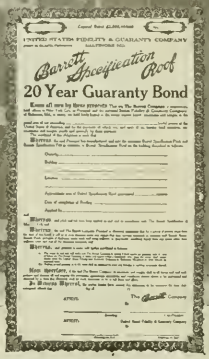
Toronto, Ont.—Trenches are being excavated on the University campus for construction of water pipes to irrigate the large lawns.

York Township, Ont.—By-laws have been passed providing for construction of water works system in Sections A. and B., construction of sewers, streets and sidewalks. Total estimated cost, $211,315.16.

York Township, Ont.—Ratepayers of Birch Cliff district have decided that work on the construction of a local water system should commence at once. A pumping station will be located on lake shore and the area to be served contains three square miles. Estimated cost, $100,000. Reeve, J. G. Cornell. Engineer, E. A. James, Toronto.

York Township, Ont.—Contracts have been awarded by township council for construction of water mains as follows: To Peter Iles, Mitchell Ave., $1,220.28, Morningside Ave., etc., $2,038.88, Amherst Ave., etc., $6,438.48, Northcliffe Blvd., $586.95, Lauder Ave., $3,365; to Murphy Contracting Co., Craydon Ave., $3,937.72; to A. Cavotti, Northland Ave.,

Barrett 20-Year Specification Roof on the Mercury Mills, Hamilton, Ont. Engineer and Architect—C. T. Main, Boston, Mass. Roofers—Dennis and Jocelyn, Hamilton, Ont.



This is the bond that guarantees your roof for 20 years.

Cover Your Investment with a 20-Year Guaranty Bond—

Every one knows that a structure of concrete and steel will endure for a generation and more.

But how about the roof that covers the structure?

Frequently that is not only an unknown quantity but a *liability* rather than an *asset*.

It is a short-sighted and costly policy to put a *poor* roof on a *good* building.

As one of the oldest and largest manufacturers of materials used in constructing roofs, we have done our part to make *all* roofs *good* roofs.

Years ago, for that reason, we induced the leading architects and engineers to unite in the adoption of The Barrett Specification as a satisfactory *standard specification*.

Now we go a step further by sending our Inspectors to check up on the construction, and if they find that The Barrett Specification has been properly complied with, we will, without charge, issue a 20-Year Guaranty Bond *exempting the owner from all further expense for repairs or up-keep on that roof for twenty years.*

This service may be had on all roofs of fifty squares or larger in all towns of 25,000 population or more and in smaller places *where our Inspection Service is available.*

Our guaranty is a real Surety Bond issued by one of the largest Surety Companies in the world. Our only requirements are that The Barrett Specification dated May 1, 1916, shall be strictly followed and that the roofing contractor shall be approved by us and his work subject to our inspection.

Thus, in spite of the fact that we do not build roofs ourselves, we are put in a position where we can guarantee the delivery of the long years of service which these roofs are capable of giving.

A copy of The Barrett 20-Year Specification, with roofing diagrams, sent free on request.

The Barrett Company LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER
ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

etc., $3,086.41, Cliff St., etc., $4,903.50. Rejected tenders, Murphy Contracting Co., Mitchell Ave., $1,656.75, Morningside Ave., $2,586.60, Amherst Ave., $6,769.10, Northcliffe Blvd., $777.80, Lauder Ave., $4,473.50, Northland Ave., $3,328.56, Cliff St., $5,117.50. A. Cavotti, Mitchell Ave., $1,389.88, Northcliffe Blvd., $709.94, Lauder Ave., $4,270.50. Frank Barber, engineer, 40 Jarvis St., Toronto.

York Tp., Ont.—Township council intends to construct 6-inch cast-iron water mains, together with all specials, valves, hydrants, etc., on (1) Belvidere Ave., from Oakwood Ave. easterly to Alameda Ave., 680 ft., estimated to cost $3,900; (2) (a) Forest Hill Rd., from Spadina Rd. southeasterly to Huron St., 936 ft.; (b) Huron St., from Coulson Ave. northerly to Forest Hill Rd., 2,730 ft.; (c) Burton Rd., from Kendal Ave. westerly to the west end, 690 ft.; (d) Claremount Rd., from Bathurst St. easterly to east end, 430 ft.; (e) Westmount Drive, from Bathurst St. easterly and southerly to south end, 1,321 ft., estimated cost, $24,000; (3) (a) Sunnybrae Cres., from Weston Rd. south-west, northwest and north to Bartonville Ave., 1,168 ft.; (b) Denarda St., from Weston Rd. easterly to Marston St., 367 ft., cost, $6,000; (4) (a) Corbett Ave. (formerly Florence Ave.), from Jane St. easterly to east end, 1,774 ft.; (b) Mould Ave. (formerly Hannah Ave.), from Pritchard Ave. northerly to Corbett Ave., 235 ft., cost $8,000. W. A. Clarke, clerk.

LIGHT, HEAT AND POWER

Halifax, N.S.—The Nova Scotia Power Commission has decided to obtain estimates on the cost of developing Indian River, fifteen miles from Halifax and bringing power into the city.

Swan River, Man.—Tenders will be called shortly for an electric power and lighting plant.

Toronto, Ont.—The Toronto Hydro-Electric system will proceed with installation of an electric lighting system in the Woodbine Heights district, York township.

Toronto, Ont.—The Hydro-Electric Commission is experimenting with a new type of lamp, which, if successful, will be placed in general service to illuminate the streets of Toronto. Commissioner Chisholm.

RAILWAYS

Bluesky, Alta.—Ratepayers are preparing petition requesting construction of a branch line railway to townsite of Vanrena, Alta.

Edmonton, Alta.—The Dominion government will consider purchase of the McArthur railways in the Peace river district, to be operated as part of the Canadian National Railways. Premier Stewart, Alberta.

Galt, Ont.—Hydro-Electric Power Commission will have estimates of cost of hydro-radial construction completed in time for by-laws to be submitted by January 1st, 1920. A. W. Mercer, mayor.

Hamilton, Ont.—Controller Halcrow, who has been actively interested in Hydro-Radials since Hamilton carried the by-law at the last election, announced last week that the Toronto-Hamilton Hydro line would be started in the near future, and that the work would be rushed to completion.

Hamilton, Ont.—City council has passed a resolution requesting the Hydro-Electric Power Commission to survey, lay out, construct, build, equip and operate a railway and to acquire lands and yards, sidings and other facilities for railway traffic east of the city; to provide yards for the accommodation of the T.H. and B. Ry. Co., in lieu of the present Kinnear yards. Estimated cost, $300,000.

Hawarden, Sask.—Joint request from the ratepayers of Hawarden and Saskatoon board of trade will be made to the C.P. Ry. for construction of the Hawarden-Saskatoon extention. J. R. Wilson, Saskatoon.

Ottawa, Ont.—It is expected that the G.T.R. Co. will agree to arbitrate question of rentals for their lines in Canada to the C.N. Ry. Estimated annual rental, $3,600,000 to $5,000,000.

Prince Albert, Sask.—The spur tracks from the C.N. Ry. and G.T.P. Ry. into the stock yards will soon be completed. The runways and loading platforms will be constructed immediately. J. M. Paul, managing director, stock yards.

Toronto, Ont.—Plans for construction of the proposed Mount Pleasant car line have been prepared and submitted to the Railway Board for approval.

Windsor, Ont.—Plans are being prepared for construction of hydro-radials from Windsor, connecting the border cities with points eastward as far as Toronto. Sir Adam Beck, chairman, Hydro-Electric Power Commission.

FACTORIES AND LARGE BUILDINGS

Amherst, N.S.—Town council proposes to erect a skating rink.

Amherst, N.S.—Barry D. Best proposes to erect a 3-story brick building on Electric St.

Amherstburg, Ont.—Tenders are being called by the Imperial Bank of Canada for the erection of a new building. Head office, Toronto.

Biggar, Sask.—Plans are being prepared for a modern hospital and 10-roomed nurses' home. J. Melrose Morrison, Regina, architect.

Brantford, Ont.—The G.W.V.A. has purchased the old post office building from the city council and will make extensive alterations. Estimated cost of remodelling, $75,000.

Brantford, Ont.—The Dominion Steel Products Co. has announced that, on account of objections by Mayor Macbride against the closing of Leonard St. for a large extension of the company's plant, the firm had decided not to go on with the contemplated work.

Brockville, Ont.—The town council has passed a by-law making applicable to Brockville the recently enacted Ontario Housing Act.

Chatham, Ont.—Building permit has been issued to the Bell Telephone Co for construction of a new exchange building. Estimated cost, $46,000. Contractors, Secord Bros., Brantford.

Chatham, Ont.—A brick building, 400 ft. long, owned by the Dowsley Spring and Axle Works, was completely gutted by fire last week. Loss, about $50,000. W. G. Sprague, manager.

Chatham, Ont.—The local lodge of the Knights of Columbus have decided to erect a new parish hall.

Cliffdale, Alta.—Tenders will be received until noon, September 21st, for erection of a frame school building. A. L. Hilsabeck, secretary-treasurer, Cliffdale school district No. 3687.

Corbyville, Ont.—Work has commenced on the erection of a new grain elevator. Concrete construction.

Dundas, Ont.—Alexander Motherwell of Canada, Ltd., are making extensive improvements and enlargements to their plant. Two large grain storage bins are being constructed to the rear of the plant and considerable new machinery is being installed. Enlarged capacity of plant, 10 cars per day.

Goderich, Ont.—An 1,100-acre site has been purchased by the Lake Huron Steel Corporation for their new plant here.

Guelph, Ont.—Tenders will be received until September 22nd, by the department of public works, Ontario, for construction of an apiary building at the O. A. College, Guelph. Plans, etc., Bursar's office, O.A.C., and Parliament buildings, Toronto. H. F. McNaughten, secretary.

Halifax, N.S.—The building on Granville St., occupied by the Dominion Express Co., is to have a three-story addition on the south, and the excavation for the foundation is now being made. The addition will be of brick.

Burlington Steel Co., Ltd.

Hamilton, Canada

STEEL BARS

For

Concrete Reinforcing

THE MOST IMPORTANT FACTOR IN CONCRETE REINFORCEMENT IS THE TENSILE STRENGTH AND ELASTIC LIMIT OF THE REINFORCING BAR.

OTHER THINGS BEING EQUAL, STEEL HAVING THE HIGHEST ELASTIC LIMIT, OR YIELD POINT, WILL BE THE MOST SATISFACTORY FOR REINFORCEMENT. WHEN UNDER STRAIN, AS SOON AS THE ELASTIC LIMIT OF ANY REINFORCING BAR IS REACHED, THE METAL STRETCHES RAPIDLY DECREASING IN SECTION, DRAWING LOOSE FROM THE CONCRETE AND DESTROYING THE MONOLITHIC BOND EXISTING BEFORE THIS POINT IS REACHED THEREFORE, THE SAFETY OF THE ENTIRE CONSTRUCTION IS IN DIRECT PROPORTION TO THE ELASTIC LIMIT OF THE STEEL USED.

THE ELASTIC LIMIT OF RAIL CARBON STEEL IS 50,000 TO 60,000 POUNDS PER SQUARE INCH, EITHER TWISTED OR PLAIN, AS COMPARED WITH AN ELASTIC LIMIT OF 25,000 TO 30,000 POUNDS IN SOFT STEEL.

THAT'S WHY RAIL CARBON STEEL, WITH ITS 80,000 POUNDS MINIMUM TENSILE STRENGTH, IS RECOMMENDED AS BEING FAR SUPERIOR FOR ALL KINDS OF REINFORCED CONCRETE WORK.

AT OUR HAMILTON, ONT., WORKS WE BUY SELECT RAILS, AND ROLL THEM INTO RAIL CARBON STEEL REINFORCING BARS IN A PLANT WHICH IS THE EMBODIMENT OF THE LATEST THOUGHT AND PRACTICE.

THESE BARS CAN BE SUPPLIED FROM STOCK IN VARIOUS SIZES, LENGTHS AND SHAPES. WE CAN ALSO ROLL SPECIAL SHAPES AND SIZES TO FIT YOUR PARTICULAR REQUIREMENTS.

Bars bent to shape for Beams, Stirrups, Etc.

PROMPT SHIPMENT

Hamilton, Ont.—Wood, Alexander and James will construct a new warehouse at Ferguson Ave. and King William St. Estimated cost, $280,000.

Hamilton, Ont.—The building committee of the Board of Education recommended to the city council that the bulk tender of W. H. Cooper for the erection of a 12-roomed school on Hunter St. West for the sum of $98,775 be accepted.

Hamilton, Ont.—Permits for construction work totalling $450,000 have been taken out by the Frid Construction Co. Three important works are included. One is the new building on Hughson St. North for the T. Eaton Co., Ltd., a $100,000 structure; another, the $280,000 building for Wood, Alexander and James, at the corner of King William St. and Ferguson Ave., and the third, the new $15,000 building for the Smart-Turner Machine Co.

Kerrobert, Sask.—A new union church building will be erected here. Pastor, Rev. Harold Marshall. Estimated cost, $15,000.

Kimberley, B.C.—Tenders will be received by the department of public works, Victoria, until 12 o'clock noon, September 22nd, for construction of school. Plans, etc., office of government agent, Vancouver and Cranbrook, B.C. and W. W. Burdette, Kimberley, B.C. A. E. Foreman, engineer.

Kingston, Ont.—A plan is on foot for the reconstruction of the Barriefield hutments into permanent barracks. Kingston also has a scheme for a union railway station.

Kingston, Ont.—G. Y. Chown has subscribed $10,000 toward the erection of a public library building conditional on a further amount of $40,000 being secured for that purpose.

Leamington, Ont.—The town council will purchase a site for the erection of a school. Clerk, R. M. Selkirk.
